The great argument for advances is, as is asserted, to secure year after year the same men, men whom you have trained to your standard of work. I sympathize fully with those who are actuated by his motive, but cannot the object be attained by different means? I don't say it can, I simply put the question. I am asked whether I am so simple as to believe that if estate owners do not give advances, the system will die out. Certainly, as far as estates are concerned, it will, but peelers are indebted to kanganies and to everyone who will lend them money. I will detail further on my experience of the system of advances by kanganies.

I do not think I anywhere said that the terms of the three years' engagement are enforced. That the engagement entered into is for three years cannot be denied. That peelers undertake pruning I am aware of, but they might I think be encouraged to do mamoty work by giving each kan-

gany a field of cinnamon to weed, prune, and do everything on contract. They are used to contract work and they like it. Mamoty work on sandy soils is not hard, and they need not work on their contracts during the heat of the day unless they like it. Mr. Jardine is mistaken in supposing that the peelers are so habituated to a sedentary life and in "cool and well ventilated *waddys*" that they shirk open air work. A good many peelers are *Goyiyas* or cultivators as well.

In reply to "Anti-Slavery" I say that the great evil in the system of giving advances is the time of the year when they are given. The temptation to misuse the money at that particular time is very great, and we deliberately put temptation in their way by giving them advances then. I do not deprecate contract service. We guard ourselves by it. Enter into a contract with our men when they actually enter into our service and ratify it by a small advance for the support of their families while they are away.

In my first letter I studiously avoided speaking of myself like the Biblical Pharisee, and saying that I am not as other men are &c., &c. I wrote as if I gave advances myself. Mr. Jardine and his friend have spoken from the standpoint of those giving advances, and have drawn imaginary pictures of peelers "coming and going according to their own sweet will; working when they liked and idling when they pleased," "self-interest prompting them to leave an estate as soon as it became exhausted of the best wood," the peelers would be quite intractable and careless in the performance of his work &c. unless the are under advances which "tend to create an interest in any one estate." Let me detail my experience, which is that of one who has consistently refused to give one cent of advances to his peelers. I have never in any one year failed to secure my whole crop. Can all estates that give advances say the same? The peelers worked very steadily all through crop and did not show the least disposition to indulge in idleness. They were quite amenable to discipline (I am a martinet), and not only did they stay till the last of the crop (the leavings) was harvested, but did the pruning as well. So much for the difference between surmise and experience. Instead of peelers leaving me at their "own sweet will" the difficulty has been to turn out a man for any gross breach of discipline. My kangany from the advances till the end of a season, while to the kangany from the Southern Province I usually had to give a sum barely exceeding R1 per peeler at intervals of a month, over and above weekly advances, but well within the earnings of the men to liquidate his debt in his village for provisions given the men for the New Year or left with their families. The estate from which I write is very popular with peelers, chiefly because their accounts are squared each time peeling is stopped—one year I paid off my men four times—and because the peelers receive R1 each all round for men and boys as a weekly advance. They are able to save small sums out of these advances, to take or send home to their families. When men complain to me that their accounts are squared only once a year elsewhere, and that they in consequence have to undergo great hardships, I always point out to them that the remedy for it lies in their own hands. Don't take advances, and you will receive more weekly advances and have your accounts squared oftener than now.

Do you, Mr. Editor of the *Observer*, still think that "W. J." and his experienced friend have "fairly and finally disposed of" the question of advances after I have detailed my experience? B. [Yes, we do: so far as the vast bulk of cinnamon plantations is concerned. We have the utmost confidence in "W. J.'s" unequalled experience:

he writes from the centre of the great cinnamon district of Ceylon, while "B" is, comparatively, a junior and outsider.—Ed.]

A CURIOUS PARASITE.

Labugama, Aug. 28th.

DEAR SIR,—Can you tell us what this very curious crawling creature (like a thin worm) is? No one here has ever seen one like it before. We found it in the garden this afternoon. I hope it will reach you alive.—Yours truly, C. S. WRIGHT.

[Our entomological referee writes:—"The long slender worm sent by Mr. Wright is a *Gordius aquaticus*, or an allied species, described in Van Beneden's 'Animal Parasites,' page 178:—"It passes its youth in the body of certain insects and leaves its cradle to scatter its eggs abroad. The life of the host is never compromised, and no functional disturbance is observed notwithstanding the enormous size of the worm: they are sometimes a foot long, resembling a violin string, and have long puzzled naturalists. They are often met with in wet weather."—Ed.]

AN ENEMY OF TEA.

August 30th, 1889.

DEAR SIR,—I send you under separate cover some "poochies," well-known, I believe, as an enemy to tea. Will any of your scientific readers kindly suggest a cheap remedy for their extermination? I have seen them on tea bushes for a long time back and took no notice of them, as the injury they did seemed but trifling. Now, however, I find it is getting beyond a joke and serious damage is being done. I have had "podians" picking them out, but that is rather expensive work.—Yours faithfully, W. A. LYFORD.

[Our entomological referee writes:—"The insects received from Mr. Lyford are the caterpillars of a moth belonging to the genus *Psyche*. They attack the leaves, bark and certain parts of trees and shrubs. Collecting them by hand, I fancy, is the best way of destroying them or in mitigation of the mischief they do. On the least approach of danger, they retire into their faggot-like case, and remain motionless until it passes."—Ed.]

A NEW TEA ROLL-BREAKER AND SIFTER.

DEAR SIR,—I wonder some of your regular correspondents have not given you the information that tea planters have at last got a perfect roll-breaker and sifter combined. I put myself in the way of seeing one at work, and I came to the conclusion that the machine is far and away the best and simplest one as yet before the public.

The machine has been invented by Messrs. Walker & Greig's Manager at Lindula, and for a wonder he has been too modest to secure his entire rights. There is now, I hear, a run on the machines; so you may depend, this is not the last you will hear of them. I have ordered one and I know of two friends that have already got them at work. There is no breaking up of the roll by hand: you take the roll from roller and put it in to the sifter and there you are, 200 lb. in 4 minutes and work perfectly done.

I have also seen their new tea sifter, a most complete machine, but I won't say any more in case you will charge somebody for an advertisement. I hear there is to be an engraving and advertisement sent to your paper.—Yours,

OLD HAND.

[Has "Old Hand" seen Westland's Patent at work? We believe it will be hard to beat, but the more of invention we have the better.—Ed.]

TEA CULTURE AND PREPARATION: No. XIV.

ANSWERS TO QUESTIONS.

1. When $\frac{1}{4}$ of field or more has "shut up,"—prune those that have closed.
2. Leaving dummy and 2 leaves on primary shoot. On secondary shoot, dummy and one leaf.
3. From 35 to 40 per cent.
4. Certainly, and thoroughly dry throughout. Not where the tea has been sifted after 1st roll—except where chulas are used.

TEA PLANTED ON OLD COFFEE LAND.

No. H.

- | | | |
|----|---|-------------------|
| 1. | 18 months to 2 years' say | 0 lb. per acre. |
| 2. | 50 per cent 2nd to 3rd year | 75 " |
| 3. | 50 " over 3rd year | 107 " |
| 4. | 100 " " 3 to 4th year | 214 " |

A. E. WRIGHT.

New Brunswick, 7th Sept. 1889.

CACAO IN WATTEGAMA DISTRICT.

Wattegama, 7th Sept. 1889.

DEAR SIR,—I have sent you by this train a cacao pod for your inspection taken from a hybrid forastero cacao tree on Wattegama this day. The pod measures eleven inches in length, thirteen and half inches in circumference and weighed when plucked 3 lb.

The tree stands in what some people called poor soil, is now four years old and measures nineteen feet three inches in height, seventeen feet and six inches in width, and stem twenty-seven inches in circumference at a foot above the ground.

We had a good cacao crop last year and will have a better one this year.—Yours faithfully,

J. HOLLOWAY.

[The pod is certainly a splendid one—13 inches long, 11 $\frac{1}{2}$ inches in circumference, and weighs 2 $\frac{3}{4}$ lb.—Ed.]

TURTLE OFF OUR SOUTHERN COAST.

DEAR SIR,—In reply to your letter of the 22nd instant, I have the honor to inform you, that numbers of Turtle use to come on shore at the Island called Ama Doowa during night to lay eggs. People use to walk in search of them during night to fetch eggs. Meanwhile, if they met any flower turtle they use to take the skin of the said animal and let the animal to sea. This people collect the skin and sell; if the thickest skins, they sold for high price; the skins are bought to make combs and boxes &c. Traders are buying the following articles, Elk and Deer Horn, Hides of Buffalo, Elk, & Deers and Cheeta, for various prices.—I am, dear Sir, your faithfully,

B. H. MUTALIPH.

JOHORE NOTES, Aug. 17th.—*Planting.*—I understand that a Mr. Milne from Ceylon is at present in charge of the estate managed by the late Mr. Parrinton, whose sad end called forth so many expressions of regret and sympathy. The coffee crops appear to be very satisfactory this year: in fact in some cases almost too much so; for I hear of one man whose crop has run quite beyond his machinery power: and on another estate an engine and boiler with other machinery have had to be put up in a hurry to work off the crop. If this sort of thing continues, and there is every hope it may, a few more years and we shall see Johore well up as a coffee producing country.—*Cor., Singapore Free Press, Aug. 19th.*

THE TRADE IN KOLA NUTS in the British settlements of Gambia (West Coast of Africa) is increasing. The imports during the year 1887 were 356,579 lbs. and in 1888 409,735 lbs. The import duty of 1d per lb. on the nuts has recently been reduced to $\frac{1}{2}$ d per lb.—*Chemist and Druggist.*

PLANTING IN WYNAAD.—August 30th.—At last we are enjoying a break, after a most unusually long interval of uninterrupted rain: about ninety days in succession, on each of which rain fell. The actual measurement is by no means excessive, though some parts of the district, notably those bordering on the ghats, have suffered in double proportion to the inland estates. But the great length of time without a gleam of sunshine has caused considerable anxiety, and the present break has only just come in time to save our crops from rotting off the branches. As it is, I notice a most undesirable amount of leaf rot, and rust, the inevitable results of such long continued damp. Crop prospects are moderate or perhaps appear more so, from the fact of our having been led to expect a bumper, as the result of the most magnificent blossom which has been for many years in Wynaad. This, however, but very partially set, owing to the terrific drought of last hot season. When the estates have been highly cultivated, however, the crops are not bad and, if the present prices hold, we may consider our present outlook a fairly cheerful one. It is being more and more forcibly borne upon all practical planters that high cultivation is an absolute necessity. Starving land is no true economy, and those who persist in working their estates on the old principle may expect to have them abandoned in a few years, whilst the improvement wrought in old coffee, (apparently quite worn out) by generous treatment, is little short of marvellous. Young plantations may be made or marred by their treatment during that period when heavy manuring is absolutely requisite to enable them to form strong wood suitable for the bearing of heavy crops. Estates well and regularly manured, will endure the trials of leaf disease and drought, with but small subsequent damage, whilst equally fine looking trees un-nourished will succumb with melancholy rapidity to the troubles that coffee is heir too. I was amused to see a paragraph in your journal, quoted from Ceylon, suggesting figs planted amongst coffee as a means of preventing leaf disease. Most of our estates now-a-days, are shaded by figs, the foliage of which is especially agreeable to coffee, but I have never before heard of them as a preventive of leaf disease. That is, I fancy, considered as tolerably incurable, but its evils effects may, and are—as I said before—considerably mitigated by heavy manuring. The estates generally are looking very healthy in spite of the damp troubles. And this break is splendid for the work, so that our trees are looking as we love to see them, clean, and tidy, after being weeded and handled. Talking of coffee reminds me that my small Liberian patch has really paid its way this year. The wonderful growth and cropping of the trees has at last attracted notice, and I have regretfully had to refuse applications for seed from it, being unable to supply sufficient. In fact I heartily wish I had several more acres of it in bearing. Every spare corner of our estates is now being planted up with suitable stumps for the support of pepper. This has been a splendid season for the cuttings, and far more than the usual percentage of these appear to have struck, whilst those plants which are already established, have thrown out exceedingly vigorous shoots. Cichona is still rather a sorrowful subject; the more so that something has evidently gone wrong with the succibras. Whole patches of these are dying out, from no apparent reason, and are an exceedingly melancholy spectacle to behold. The ledgers seem all right, and possess this advantage, that if of little present value, they at least do not cost much to cultivate, although, be it noted, like all other things, they prefer generous treatment to starvation! * * * Several new openings of forest land have been made this year, and altogether, I think, I may truly assert that the spirit amongst planters is more cheerful and hopeful than it has been for many past seasons.—*Madras Times.*

IMPROVED SUGARCANE.—The Queensland Government have secured supplies of plant cane from Baron De Lissa's plantation in British North Borneo. These were originally from Queensland, but the North Borneo climate had vastly changed the canes for the better.—*Straits Times*, Sept. 4th.

CINCHONA PROSPECTS.—We print on page 257 another long letter from Baron von Rosenberger on the need for a Syndicate of Cinchona planters; but it will be observed that not only have the Uva, but also the Wynaad planters decided that it is impossible to work a Syndicate to check the harvesting and shipment of bark now-a-days from the East. We observe that several of the South of India Planting Companies now bemoan the position of bark in the home markets very bitterly. The Tambrachery Estates Co. Ltd. has had the disappointment of a very short coffee crop owing to drought, and while they got of bark $\frac{1}{3}$ rd more than the estimate or 128,000 lb., the price is so miserably low, that they have determined to hold their stock some time longer. This is the Company for which Mr. Jowett, well-known in Ceylon is manager, and the expectation being of a steady rise in bark—soon, this is what the Directors write:—

“The intrinsic value of the company's property will naturally augment concurrently with the price of bark and, should a steady rise take place from now, the company will be exactly in a position to profit by it, as none of the regular fields of cinchona have yet been touched, and the first harvest from any of these will occur this year, the estimated shipments being 175,000 to 200,000 lb., without including any of the more valuable varieties. The manager, Mr. Jowett, advises that he will not be in a position to make an estimate of the probable coffee crop until September. The drought lasted up to the period of first blossom, and unfavourably affected it on some estates; but the second blossom has apparently been more fruitful, than usual though to what extent cannot yet be stated with any degree of certainty.”

“The Wentworth Gold Company” has, it seems, for some time expected more from cinchona than from gold, but, alas, the long-expected rise in price seems as if it would never come. We read:—

“The new chairman, Mr. Robert Ewing, says it is conceded that the price is now so low that it does not cover the cost of production, and it is unreasonable to suppose that such a condition can long continue; and with a falling off in supply it is natural to expect a rebound in values. Taking these circumstances into account, the board consider it would be a mistake to force the stock they hold upon the market; so to put them in funds to carry on the work of the estate, they have made a call of 1s per share upon the uncalled capital. It has also been decided not to bring home any large quantity of bark this season. The stock in hand costs comparatively little to hold, and a rise of 1d per unit would make a difference on it of over £2,000. This company has 571 acres under cinchona, 156 acres under coffee and cinchona combined, and 15 acres under coffee alone, making 742 acres out of 1,300 acres. As soon as cinchona goes up in price, the managers will liberate the coffee and cut down the cinchona to give the coffee a chance.”

So, Ceylon planters will be able to judge that there are considerable stocks of Indian bark held ready to go on the market, apart from what may remain in local estate stores or in Colombo. During the last few weeks, it is said, Colombo stores have been pretty well cleared; consequently as regards the current season, Ceylon estimates are likely to be out again considerably, for we are in a fair way to see 10 or even 10½ millions lb. shipped before the end of September! Everyone is quite sure “this cannot go on; it is impossible; the country is wellnigh cleared of all bark; there is no more to come; there will be a sudden collapse in shipments”—and go on. But meantime, the bark somehow comes to the front!—Mr. Bell's news from Java is not re-assuring.

JOHORE 31st Aug. Johore has just been visited by Mr. Thurburn of Shanghai, who has been to visit his coffee Estate “Drum Duan” on Gunong Pulau. He is firmly convinced of the future of coffee; and for my part I would rather own coffee than any other tropical product at the present time. The future production of Java will never materially affect the market. Ceylon is exporting barely one tenth of what she did ten years ago; and the manumission of slaves must be a severe blow to the coffee trade of the Brazils. Mr. Editor, can you not give us some figures as regards last year's and this year's crops; and next year's prospects in the last-named country?—*Cor., S. F. Press.*

JOHORE NOTES, 21st Aug.—After goodness knows how many months of rain, we have actually had ten consecutive days of fine weather. Rain however, again fell this morning; but the general appearance of the weather encourages us to hope for more sunshine. As may be imagined with such continual wet, weeds have flourished; and I know of more than one estate that a fortnight ago looked more like a homely old hay-field than a tea or coffee estate! However the last few days sunshine have done us yeoman's service; and the area just cut presents a very different appearance to that weeded previously, where the grass simply laughed at us; and what we pulled up today was growing tomorrow! Besides giving trouble as regards weeds, the weather has been very detrimental to the process of drying coffee; and as the crop season has been in some parts, at its height, the inconvenience experienced has been very great.—*Cor., S. F. Press.*

CONSUMPTION OF RICE IN MAURITIUS.—The Chamber of Commerce and the Brokers of Port Louis have been considering the demand of the colony for rice, and they have reported as follows:—

That the quantity found by both Chambers, viz 252,533 bags should be adopted as the approximate Stock of Rice in the Colony on the 10th June 1889; and that this figure should be taken as a basis for future Returns.

That the quantity of 2,400 bags should be maintained as being approximately the daily consumption for Mauritius and its dependencies, except Seychelles, the Committee seeing no reason to alter this figure, as, had the daily consumption been in excess of this estimate since 1878, when this figure was adopted, there would at present be nothing like the Stock actually existing.

That the exports of Seychelles should no longer be included in the stock on hand, Mahé being now an independent port having a Custom House of its own.

JAVA (CINCHONA) AND THE STRAITS (OLD FRIENDS).—Mr. G. D. T. Bell of Newton returned by the “Yang-Tsé” after his brief visit to the Straits and Java. He speaks very favourably of the comforts of the voyage in the M. M. steamers both ways; he had ten days to spare at Batavia and ran upcountry, visiting Mr. Mundt and one cinchona plantation recommended by him. This was an extensive Ledger plantation of some hundred of acres, trees perhaps 8 to 10 years old, yielding bark of a splendid analysis and *no sign of canker or dying out*. Moreover, and this surely is very important, Java planters are able to plant up in place of the trees they thin out and the supplies put in this way, invariably grow! Mr. Bell noticed too how the grass and weeds were allowed to grow between the cinchona: to cut them down two or three times a year being sufficient. Altogether he concluded Java is especially the country for a permanent cinchona-growing industry. He inspected one of the Government Gardens, but it was of *Succirubra*. Coming back, Mr. Bell met in Singapore, Mr. Parrinton, looking well, only three days before his death from hydrophobia: Mr. Milne had succeeded him in Johore; Mr. Turing Mackenzie is flourishing in the same district, very busy and pleased with his prospects. Mr. Fischer of the Hotel looked well and flourishing.

A CINCHONA SYNDICATE FOR JAVA CEYLON AND INDIA.

We call the special attention of the Ceylon Chamber of Commerce, Planters' Association, and of our merchants and planters generally, to the letter (see page 259) from the Soekaboemi (Java) Agricultural Association. We think no harm but good would result if, at this critical time in the Cinchona bark trade, representative men were chosen in Java, Ceylon and India to correspond with each other on the subject discussed so freely in our columns of late. Baron von Rosenberg of North Travancore, and Mr. Jowitt of Wynaad might well represent the principal Indian Cinchona districts; Messrs. Osborne and Talbot* as Chairmen of the Badulla and Dimbula Planters' Associations—our only districts with Cinchona cultivated to any extent now—together with the Hon. W. W. Mitchell, should represent Ceylon; while the gentlemen who write to us, Messrs. Mundt and Eekhout have already pledged themselves to do all in their power in Java. One matter of great practical importance is, our readers will see, already taken up in Java, namely the regulation and reduction of the export of bark from the Government Gardens; and the Java cinchona planters are evidently well enough off to agree to do what is more difficult to effect in Ceylon. On the opposite Continent, however, large holders of bark can be more easily brought into the compact and something may also be done about the export of bark from the Government Gardens in India. As we stated before on reliable authority, the very fact that Java, Ceylon and Indian owners of bark are moving in the direction of a Syndicate to regulate exports from the East, cannot fail to have an improving effect on the markets in Europe. We trust therefore, that the gentlemen we have named in India and Ceylon will not refuse to second the efforts of Messrs. Mundt and Eekhout; and we would ask Mr. Mitchell who has already shown a practical interest in the subject, by his speech before the Chamber of Commerce, to take the initiative.

AMOY OOLONGS FOR THE AMERICAN MARKET.

A report of Consul Crowell on Amoy Oolongs notes:—There was a shrinkage of about 23,000 half-chests in this season's crop as compared with that of the year before, but their inferiority has been fully sustained in the quality of this year's teas. A large percentage of the Amoy Oolong is poorly cultivated, poorly picked and cured, dirty, and adulterated. "Stuff" it was called by the Amoy commissioner of customs in his last year's annual report, and he added that the stuff "was alone wanted in America." This is, unfortunately, true, for nearly the whole crop of Amoy Oolongs—bad and often unfit for use as they are—are annually marketed in the United States. The American people are better able to use and pay for a good article of tea than the people of any other nation. I am certain it is not the tea-drinking public in the United States that causes this inferior stuff to find a market only in America. It is the greed of importers and exporters that alone makes it possible to impose this vile stuff, by excessive courtesy

* Should Mr. Talbot personally have no interest in cinchona, one of his Committee members from the Agras division of Dimbula could act.

called tea, upon the American public. I have several times called the attention of the Department to the stuff called Amoy Oolong. I now beg to repeat my suggestion with increased emphasis, and to hope that the tea-drinking public at home may be protected against this so-called tea known as Amoy Oolong. I repeat my suggestions at this time, when all the last year's crop has been marketed and before the new crop comes into market, that it may not be thought I have any desire to affect the market of these teas or to accomplish any other purpose except that of preventing them from being dumped into the New York market, and then, by some occult means, imposed on the public.

The law relating to the importation of bad and adulterated teas into the United States is sufficient, if enforced, to protect the public against such spurious teas.

Every invoice of Amoy Oolongs that reaches New York or San Francisco should be rigidly inspected, for anything branded as Amoy Oolong is open to suspicion as being bad or badly adulterated, and hence every invoice of these teas should be most carefully examined at the custom-house. This would afford some protection to the American public. It will make importers and exporters more wary about dealing in the stuff, and it will tend to improve the quality of the future product in this district. The Chinese tea growers and merchants will never improve their method of cultivating, curing, and handling their teas until they find that they cannot sell them without making some improvement.—*L. & C. Express*, Aug. 16th.

PROSPECTS OF GRAIN CROPS IN BURMAH.

The *Rangoon Gazette* hears that in consequence of the rains being unusually late and light that in Lower Burma more especially, it is probable that the amount of land placed under cultivation this season will be smaller than usual. It is true that in Upper Burmah, despite the cattle disease that has done much damage in places, more land is being worked: and here the crop is fortunately not so dependent on the monsoon as on the rise of the Irrawaddy and its tributaries. Still the flood is late, and the river is still lower than usual at this time of the year. It is, of course, impossible to even guess at the quantities that may be ultimately available for export. So much depending on the outturn. A few weeks before harvest makes all the difference between failure and a bumper yield, the actual area under crop having little to do with the result. With anything like an average harvest in the Upper Province of which there seems every hope, the demand for up-river is not likely to be heavy, and the bulk of the local surplus will consequently be available for export—From Siam accounts are favourable; but China and the islands are likely to make heavy draughts in the event of a light yield, as the floods in the one and vague political uneasiness in the other seem to have thrown much land out of cultivation. War in Europe, which is becoming more and more a possibility, will cause a big demand with high prices, and would certainly stimulate production, as a protracted struggle would mean large orders for all cereals. Stocks are low at present and heavy sales for delivery have taken place.—*Indian Agriculturist*.

DISCOVERY OF GRAPHITE IN MICHIGAN.

The discovery of the Baraga Graphite Mine, in northern Michigan, promises to develop into a matter of more than ordinary importance. The mine has been known to exist for several years, but it was not until very recently that the product of it was recognized as carbon, and more recently still that the carbon was of sufficient purity for commercial uses. Graphite comes from this mine in large chunks as it is blasted, and is then easily subdued to a merchantable form. For the purpose of reducing it the same process is adopted as that used in grinding wheat, although there has not yet been any successful experiments in using the

"patent roller process." The old-fashioned burr stone grinds the graphite, and it is afterwards bolted like flour and sold according to its grade of fineness.—*American Exporter*. [Ceylon graphite is sold in lumps and dust, but never ground. The grinding process is performed at the manufactories of crucibles, &c.—Ed.]

NOTES FOR CEYLON READERS.

Ceylon is not enjoying any monopoly in pioneering British grown tea at the Paris Exhibition, if we may judge from a little *brochure* put forward by the Indian Tea Districts Association, wherein it is set forth that "Pure Indian tea of different kinds are sold at moderate prices in prettily-designed packets of various sizes, and small envelopes containing enough for one or two persons furnished to travellers. Large quantities are sent from the depot which has already been opened, No. 204, Rue de Rivoli, and export orders supplied according to each standard direct from London. All prices are arranged with a view of inducing large shopkeepers in Paris and throughout France to take up and push the sale of the teas. As an inducement to accept the agency, advertisement in the Indian Palace and in a small illustrated pamphlet are offered. Considerable labour has been expended upon the production of this little book. It is illustrated in the French style of art, and represents the various classes of society in France drinking Indian tea, the virtues of which are commended in suitable brief letterpress. It is intended to be constantly distributed at the Indian Palace, whilst the Exhibition continues open and in itself should effect a revolution in the French conceptions of India tea." It appears from the above that a retail business has already been commenced in the French capital; this will, of course do something towards relieving the London market of a certain quantity of Indian tea and so help to steady prices all round.

Ceylon exporters of plumbago to the United States will be interested in an announcement recently made to the effect that an immense vein of this substance has been found in Southern California, about twelve miles from Los Angeles and adjoining the town of Crescenta Canyon. Assays of the ore show it to be of superior grade and richness. Specimens assay as high as 80 per cent plumbago.—*Ceylon Advertiser*.

SUGAR CULTIVATION IN QUEENSLAND.

It is only some twenty years since the sugar cane was introduced into Queensland and every effort made to foster the industry by offering bounties for the first 500 tons of sugar made in the colony; and now what do we see, but the Government, urged on by the democratic element resulting from free emigration from Europe, distinctly refusing to continue the importation of Kanakas, and if this course is persisted in, the sugar industry in Queensland *must be abandoned*. Those who are acquainted with the subject know very well that in climates where the cane flourishes best, white labour for certain field operations is an *impossibility*, be the wages ever so high, and it is a lamentable fact that men of capital and energy should be obliged after years of hard work, to shut up their mills and allow the cane fields to go out of cultivation because freedom of labour is not allowed. For further particulars on this important question I would refer your readers to my article in the *Field* of May 4th, 1889.—JOHN HUGHES.

[It may have been right, in view of abuses, to stop the importation of Kanakas (South Sea Islanders), but immigration from India ought to have been allowed. The prospect now is that five millions of property will be sacrificed.—Ed.]

JAPANESE TEA.

The *American Grocer* reprints from some other work the following little note on tea culture in Japan:—The tea-plant is a shrub or bush rather than a tree. I don't know how high it might grow if left unpruned, but it is usually trimmed down to within 4

or 5 feet of the ground. I have seen the tea-plant in various places. The Japanese set the plants, three or four in a hill, the hills being 6 feet apart. It takes three or four years for a seedling to grow large enough to yield a crop of leaves suitable for gathering. The plants live many years, although the leaves are picked off two and three times a year. The first picking is in April or March, the second in June and the last in July. The leaves are thick and glossy. They are gathered in baskets, and placed over a steaming apparatus, and then dried over a gentle fire, in paper* pans. The tea is now sorted, and the different qualities are packed in jars or chests. The wholesale tea buyers who export the article to Europe and America, have warehouses at the shipping ports, where they subject the tea which comes from the fields to a further roasting process, in large iron kettles. They then repack it in such chests as you have seen at the large groceries.

This valuable paragraph is accompanied by an illustration labelled "Drying and Packing Tea," which is—will it be credited?—nothing more or less than a representation of the process of feeding silkworms! And now we suppose a large section of the population of the United States will imagine that in Japan tea is first chopped up small with a kitchen knife, and then packed in shallow little boxes upon layers of caterpillars!—*Japan Weekly Mail*, July 27th.

DURBAN COUNTY TEA COMPANY.

The first annual meeting of the above took place yesterday afternoon, in the Exchange, Smith Street, Mr. O. Dacomb presiding.

The report of the directors stated that the lease of the company's land for 21 years, with right of purchase, had been duly arranged. At their request, Mr. J. L. Hulett, M.L.C., visited the gardens, and testified to their suitability for tea planting, recommending that the whole be taken up by Dec., 1890. By 1892 the crop should produce £2,000, with annual increase. This advice had been accepted. The Manager had now 60 acres planted, and 40 ready; so it is hoped that 100 acres will be under cultivation by December. The hot summer destroyed some of the October plants. The young plants need rain badly now. Seven hundred loads of manure are awaiting use. Sixteen coolies and ten kafirs are now employed. Labour is difficult to obtain, the manager recommends importation from India.

Receipts and expenditure showed a balance of £90.—*Natal Mercury*.

[The scarcity of rain and labour is ominous.—Ed. T. A.]

VALUABLE MANURES.

Mr. Fischer, secretary for agriculture, referring in the *Agricultural Journal* to "A Treatise on Manures," a book lately published by Dr. Griffiths, principal and lecturer on chemistry at the School of Science, Lincoln, says Dr. Griffiths has, according to his statements, in a series of experiments obtained 56 bushels of dry beans from land manured with half a hundred weight of ferrous sulphate (copperas) per acre, whilst other parts of the same land without copperas produced only 35 bushels. The copperas should be superadded to the other manurial agents, and not used as a substitute, as it acts chiefly by rendering insoluble plant food contained in the soil soluble.

According to Berthelot, Gautier, and Dronin the iron oxide formed from the copperas accelerates also the process of fixing atmospheric nitrogen in a soil. In the *Journal of the Chemical Society* experiments have been published which tend to show, that under certain circumstances, not only the quantity but also the quality of a crop is improved by manuring with copperas, which also appears to act as an antidote against various microscopic fungi (Peronospora, a infestans, wheat mildew, &c.) As, however, iron (ferrous compounds) in somewhat large quantities poisons the plants, only an extended series of experiments carried on for a long period of time will solve this question satisfactorily.—*Natal Mercury*.

* Copper?—Ed. T. A.

THE TOMATO.

The tomato is one of the few plants that will pay better on a moderately poor soil. Keep away much fertiliser that makes leaves and late fruit, but use instead some form of alkali-potash, for instance, which acting upon the vegetable matter in the soil will generate ammonia enough to form as much foliage as is necessary. Sulphate of potash is most advantageous. The presence of potash in a sulphate form facilitates ripening by favouring the transformation of the starch to grape sugar. Depriving the plants of a part of their roots or foliage cause them to concentrate their vitality on ripening their fruit, and so make it earlier.—Mr. E. P. Kirby, before the Boston Market Gardeners' Association.—*Natal Mercury*.

FIG CULTURE.

(Extract from "Encyclopaedia Americana.")

Fig-tree (*ficus carica*) is a native of Asia, Africa and the South of Europe, and has been cultivated, from remote antiquity, in the countries surrounding the Mediterranean where it forms a principal article of food in many places. The stem is from 15 to 25 feet high, with a trunk sometimes 2 feet in diameter, giving out a great number of long, twisted, pliant branches, which are greyish and rough when young; the leaves are deciduous of the size of the hand having three to five rounded lobes; the flowers are very small, unisexual, contained in great numbers in a common receptacle, which is fleshy and connivent at the summit, where it is almost closed by a series of little teeth; the male flowers occupy the superior part of this receptacle, and the female, which are the most numerous, the bottom, and all the remaining part of the cavity; each ovary becomes a seed; surrounded with a pulp, which, together with the receptacle, forms the fruit. The fruit is solitary, generally of a purplish color, has a soft, sweet, fragrant pulp, and is much esteemed, being constantly brought upon the table, during 5 months of the year, in the South of Europe. The process of increasing and ripening the fruit is an art which requires much attention. This as it is practised in the Levant, is called "caprification" and is a very interesting process. It is thus described by Tournefort, and travellers in the East. The operation is rendered necessary by the two following facts, viz:—That the cultivated fig bears, for the most part, female flowers only, while the male flowers are abundant upon the wild fig-tree; and secondly that the flower of the fig is upon the inside of the receptacle which constitutes the fruit. It is hence found necessary to surround the plantations and gardens, containing the figs, with branches and limbs bearing male flowers from the wild fig tree thus preparing the way for fertilizing the female flowers in the garden. And from these wild flowers, the fertilizing pollen is borne to the other figs upon the wings and legs of small insects, which are found to inhabit the fruit of the wild fig. It requires therefore a very particular observation and careful study of the wild fruit to know the precise time when the insects will be ready to take wing, or they might be lost. When it is found they are just ready to leave the fig, the boughs are placed as above described, and an abundant crop is the result.* The fig tree, in its wild state, is a low, distorted shrub, bearing fruit destitute of any agreeable flavour. Dried figs are easier of digestion and more nourishing than the fresh fruit and form a considerable article of commerce. The best come from Turkey, Italy, Spain and Provence; those of the Archipelago are inferior in quality. Dried figs, with barley bread, are now the ordinary food of the lower classes in Greece and the Archipelago. The ancients procured a sort of wine from figs by a method which is still in use in the Archipelago. Several hundred varieties are cultivated in Europe, some of which are very excellent. In the United States, the fig is sparingly cultivated in the environs of Philadelphia, but does not succeed so well as farther South. There

* We believe that really this process is unnecessary.—Ed.

are five principal methods of reproducing this valuable tree: viz: 1. By seeds, which is but little employed, on account of the length of time requisite for bearing, and the fruit is not always of as good quality; but it is the only method by which new varieties can be produced. The figs should be first washed in water, and those seeds rejected which float upon the surface. 2. The easiest mode is by suckers, which may be separated from the roots of the old trees. 3. In the month of March or April, branches are passed through pots containing earth, which is occasionally watered to keep it moist; roots are produced with facility, and branches may be separated in the Autumn. 4. A method which requires less trouble, and is most in use, is the following: In March or April, a bough about 2 feet long and two years old is selected; the largest of its branches is reserved for the future stem, and the others are extended in the earth and give out roots; care should be taken to cover at least two-thirds of the bough with earth, otherwise the terminal shoot is not developed. 5. Grafting has been neglected, on account of the facility with which the fig may be reproduced by these two last methods. When used, a mixture of wax and turpentine is employed to prevent the flowing of the sap. The tree does not bear transplantation well, and consequently this is not often attempted. Almost every variety bears fruit twice in the season.

The species of *ficus* are shrubs or trees, with alternate leaves and branches, and having a milky, and more or less acrid juice, inhabiting the intertropical regions of the globe, a few species excepted, which are found in warm climates, though without the tropics. More than 100 species are known, the most remarkable of which are the following. *F. Sycomorus*, a large tree the fruit of which is eaten in Egypt and the Levant. The wood is said to be incorruptible, which would seem to be proved, as the cases containing the Egyptian Mummies are made of this tree. *F. Indica* (Indian fig or Banian tree) has been celebrated from antiquity, from its letting its branches drop and take root in the earth, which, in their turn become trunks, and give out other branches, a single tree thus forming a little forest. *F. Elastica*, the juice of which yields *Caoutchouc* or gum elastic, has not been long known, and is a native of the mountains of Nepal. This latter tree would probably succeed in the United States and make a valuable acquisition.

BARK AND DRUG REPORT.

LONDON, August 15th.

CINCHONA.—The periodical auctions held on Tuesday were the smallest held for several months, the catalogues only consisting of—

	Packages	Packages
Ceylon bark	673 of which	605 were sold
East Indian bark	220	220 "
South American bark	215	215 "
Java bark	81	60 "
African bark	56	56 "
Total	1,245	1,156 "

At the commencement of the auctions it appeared as if the prices paid at the preceding sale would not be improved upon, and as a matter of fact a few parcels of ordinary Ceylon bark which had been put up at the auctions of July 30th were now disposed of at unaltered values. But when the better grades of Ceylon and the Java and the East Indian barks were reached, competition became much brisker, and a decided advance on the previous sales' rates were established. This advance was rather irregular, and increased towards the close of the auctions, but we may put it at an average of from 10 to 15 per cent at least, the unit ranging from 1½d to, occasionally 1¾d per lb. Upon comparing the catalogues of Tuesday's sales with those of the auction of July 30th we find that a few lots were offered, apparently identical with those shown, and partly sold at the last auctions, or consisting of packages of the same pile, and presumably the same analysis. A comparison between the prices realised on those occasions is of a certain value as a guide to the position of the market:—

	July 30th	Aug. 13th
1 B Ceylon original succirubra shavings ...	1½d sold	1½d sold
7 B " rend. offic. chips	4½d to 5d sold	4½d to 5d
8 B " orig. succ. chips	2d sold	3½d to 4d
26 B Java orig. ledger. chips	6½d to 7d sold	8d
22 B " orig. ledger. branch chips	3d refused	3½d
12 B " orig. ledger. root	6½d asked	7½d
8 B East Indian rend. crown shavings	4d asked	4½d
4 B " orig. "	1¾d asked	2d

The following are the approximate quantities purchased by the principal buyers:—

	Lb.
Agents for the Mannheim & Amsterdam works	80,681
Agents for the Auerbach factory ...	69,234
Agents for the American, French, &c., works	61,074
Agents for the Brunswick factory ...	14,907
Agents for the Frankfurt o/M and Stuttgart works	9,818
Messrs. Howards & Sons ...	5,719
Sundry druggists, &c... ..	6,617
Total sold ...	248,050
Bought in or withdrawn ...	22,028
Total quantity catalogued ...	270,078

It should be well understood that the mere weight of bark purchased affords no guide whatever to the quinine yield represented by it, firms who buy a small quantity of bark by weight frequently taking the richest lots, and *vice versa*.

SOUTH AMERICAN BARK.—Two hundred and fifteen small bales of cultivated Bolivian Calisaya quill, altogether weighing 12,085 lb., were offered and sold, one good bright lot, rather split at 8d, the rest, dull and irregular quill at 5d to 6½d per lb. The quality was rather below the usual standard.

AFRICAN BARK.—Another parcel of cinchona from the West Coast of Africa, imported via Lisbon, was offered and sold at 3½d to 4d for weak long thin and irregular Succirubra quill, and 2d to 2½d for low to weak broken Calisaya quill. The whole weighed only 3,108 lb., and every bale was country damaged. Our imports from all sources since the last report have been 1,151 packages.

CUBEBS.—Over 240 packages have been imported this week, but four-fifths of this is said to be in transit only. Holders still quote £24 to £28 according to quality. The cultivation of cubebs is being taken up with a great deal of energy in Java, and the director of the Buitenzorg Botanical Gardens reports a strong demand for seed from several quarters.

QUININE.—The market at the close of last week entered from a passively firm state into one of very considerable activity, and heavy transactions have been reported daily at gradually advancing prices. The reported sales in second-hands total up to about 160,000 oz., nearly half of which is put down to the Brunswick, and about one-fourth to the B & S brands. About 60,000 oz. are said to have been sold on the spot at 12½d to 12¾d, and ultimately at 13d for bulk; November at 14d; December delivery at 13d to 14d; January-March at 13½d (early in the week); and February at 14d per oz. Today the market closed rather quieter though the makers' agents are selling very cautiously, and quote 1s 3d per oz. for December delivery. Last night an offer of 13½d is said to have been refused for a small lot on the spot, and today 13½d is reported to have been paid.—*Chemist and Druggist*.

CEYLON TEA IN AMERICA.

We are indebted to Mr. F. F. Street for the following:—

"Colombo, 9th September 1889. The following interesting extracts from a letter from New York written by Mr. Lenyon Parsons, formerly of Colombo, will I think interest some of your planting readers.

"My idea in writing to you is to get ready in case Ceylon Tea comes to the front here. We are ready to receive consignments both of *tea* and *cocoa*, which information if not of use to you pass on to some one to whom it will do good. I have always taken an active interest in Ceylon tea here, holding Murray's agency (of Philadelphia), but I find the grocers will not use it; hence the jobbers will not. When the public ask for it, the grocers will, then the jobbers, and then is the time for consignments. These do not I believe pay just now. It is a mistaken notion of the Ceylon people that this market is not being tried because it is, especially by representatives of London firms. I tried it myself with Murray's tea, but grocers will not take it, as they make more money out of cheap trash. This is the experience of others here besides my firm. As I happen to know some prominent grocers, I know what I am talking about. Of course the right thing is to start a retail place here and advertise. New York city is the place to begin, for the simple reason that if the public buy the tea the grocers and jobbers will, and these latter people will advertise it, through their travellers or "drummers" as they are called, of their own free will, out West. I saw a Canadian writing something about vested interests here in the Ceylon papers. There are none that will not at once disappear, when once the profit of an enterprise is shown. He might have known that in this city, at least, dollars are dollars! Show the men here that they get more for their money by purchasing Ceylon tea than Chinese and they will help you along. I always have a stock of Ceylon tea, from Murray, on hand for personal friends, and find 90 per cent of them want nothing better and *eagerly* ask for it. Having an American partner I am well acquainted with the likes and dislikes of the people here; and without that knowledge it would be much better to start an enterprise in the North Pole as far as the profit is concerned.

"The Ceylon people seem to be stumbling in the dark about the way to start a Tea Company here: surely business men must know now that they can apply to business firms and get full information in all they want to know. When I saw that a plan was on foot to sell tea in conjunction with earthenware for the purpose of pushing the interests of Tea! it made me think the Island had suffered in some way from the heat."

"I hope this new Company will prosper, as I am anxious to see Ceylon come to the front."

TEA-DRINKING IN AMERICA.

To the Editor of the *Englishman*.

Sir,—With reference to a statement in a recent issue of the *Englishman* on a matter of some importance to many of your readers, you might explain that there is no duty on tea imported to the United States in British owned vessels, or, in fact, in vessels of any country having treaties with the United States.

In order to create a market here for Indian teas, the people must first be taught how to prepare the tea. They have been accustomed of "stew" the rubbish sent here from Japan, and, in fact, have come to like it, so that it is difficult to induce even private housekeepers to take the little trouble necessary to make an infusion of Indian tea, fresh each time it is wanted for use.

The hotels and restaurants, which are the chief consumers of tea, draw each customer's supply from a huge boiler which is kept stewing all day long, and to which a handful of tea and a kettle of water is added as occasion demands. Indian tea prepared in this fashion is, of course, undrinkable, but until the public demand something different the hotel-keeper will not change, even if you supply him with Indian tea for nothing.

A. S. M.

San Francisco, California, U. S. A., July 24th.

LOCAL BUILDING MATERIAL.—BRICKS.

If there be one description of material used in building operations in Ceylon which requires improvement in manufacture more than another, it is the important item of bricks. Taking by far the larger proportion of the supply of these which is ordinarily worked up in our buildings, it may be said that they are but little more reliable, as regards their soundness and consequent capacity for withstanding pressure, than are the unburnt and merely sun-dried bricks which are used in the construction of native huts. Indeed, were it not for the ravages of the white-ant which tunnels so freely in the latter, it might be said that the unburnt brick would be as well adapted for use in the majority of our buildings as is the professedly harder burnt brick with which we are supplied. This conclusion would certainly have held good up to very recent times; but of late years the erection of dwelling-houses of more than one storey has caused the imposition of greater weight on the bricks used than was formerly the case, and the question of quality has therefore become much more important than it has hitherto been. Certainly, it cannot be said that the desideratum has as yet been supplied. The quality of the bricks obtainable in most parts of the island—we speak of outstations especially—is lamentably inferior, and we believe that much might be usefully done in the way of improved methods, both of preparation of the clay, the course of moulding, and the subsequent firing.

It is undoubtedly the case, that, as a rule, the clays of our island are deficient in that plasticity which constitutes the main qualification for producing really good bricks. Much may be accomplished, however, towards overcoming this primary defect by a more thorough weathering and tempering of the clay. We doubt very much if the first process, which is so important an element in the manufacture of bricks in England, is ever given the least attention to in this island. The clay is placed in the moulds as soon as dug out, and the result is that our bricks are so full of the faults which lead to the cracks which, after burning, are to be observed in most of them. No clay should be used which has not been spread and exposed to the weather for at least a month, and at the expiration of that period all "lumpiness" in the clay should be destroyed either by pounding or, better still, by being thoroughly trodden over by buffaloes or elephants, the latter animals at one time—and still?—being extensively employed by our Public Works Department for this purpose. During this operation watering should be done sufficiently to restore the moisture evaporated during the process of weathering. It may be said that to adopt these conditions must largely increase the cost of the bricks; but we have been told that the immunity which would be secured by them against breakage during handling and transport would go a long way towards redressing the increased cost of manufacture. It seems probable that our local demands may never be so great as to render it desirable to employ machinery either for puddling the clay or for moulding it subsequent to that operation, and as regards the second process it is universally admitted that a good hard-mace brick is superior—even if more costly—to the one produced by machinery. It was this consideration which led to the discontinuance of the use of the brick machines imported by the Ceylon Government some thirty years back or so.

It may be further urged that experience has shown that hitherto our supply of bricks, even of inferior quality, suffices for the uses for which

it is employed; but, as we have pointed out, the tendency to increase the height of our buildings makes it desirable that that quality should now receive improvement. With better bricks the thickness of walls may be materially reduced, and as in many situations the cost of transport of these to building sites is heavy, it is evident that a reduction in the number of them to be used must result in considerable economy. Then, again, there are many purposes to which bricks are applicable which demand qualities far surpassing those which may be needed for mere house building, walls constructed for the last-mentioned purpose being—owing to the wide use of verandahs—generally sheltered from the effect of damp. But they are needed for cisterns, tanks, walling for canal and river embankments, lining for wells, and many other purposes for which thorough soundness is a desideratum. Here in Colombo, it may be admitted, the ease with which cabook has been obtained has caused this question of the quality of our bricks to be very much disregarded, but the quarries available for the supply of this material are daily becoming more exhausted within the area which admits of economical transport. The sooner therefore our brickmakers endeavor to overcome the faultiness of their present procedure, the less likely it will be that the diminishing supply of cabook will be injuriously felt. Beside this consideration there is the further one that, bulk for bulk, cabook work is inferior in strength to well-built brickwork, while the indurated clay is never a reliable material in any situation exposed to the action of moisture. Nor can the resistance that really hard brick would oppose to burglarious entry through walls be overlooked in the light of many recent experiences in Colombo.

We have referred to the weathering of the clay which we would recommend for adoption. That is the first and main improvement we would suggest. But our present methods of firing are exceedingly crude, and cause the loss of a very considerable proportion of the bricks burnt in clamps. It may be admitted that wood can never be as efficient a firing as is the small coal used at home. The latter more evenly distributes the fire and does not burn out under a strong draught in the open as does wood. This comparative disability might be remedied if kilns were more commonly employed than they are. With them the strength of the draught may be regulated and a more slow and even burning secured. We feel perfectly certain that were the hints we have given followed up, although the first cost per thousand might be in excess of what it is at present, the results would more than compensate for its incurrence.

COFFEE IN JAVA.—The *Soerabaya Courant* of 22nd August says:—"The east monsoon has at last set in properly during the past three weeks, and that is very fortunate, as it would have been a very bad lookout for the coffee, since it has continued a wet year all through. Most of the coffee lands however have suffered extremely from the coffee leaf disease, and the only remedy of real benefit for lessening that is dry weather."

TOBACCO.—Reports to hand per "Paknam" from North Borneo state that this year's crop of tobacco is most promising. The tobacco grown by Mr. Van de Hoeven on the Labuk river is splendid and a great success, and upon some of the other estates the tobacco is coming on well. The labour question is becoming more serious every day, and active measures are being taken to meet this difficulty, which makes itself felt also in this Colony and Deli to some extent.—*Straits Times*, Sept. 4th.

CONSUMPTION OF QUININE IN THE STATES.—The United States should be the future saving of cinchona, as of tea, planters! We read in the *Chemist and Druggist* of Aug. 24th:—"The imports of foreign-made quinine into the United States between January 1st and August 3rd have been 1,877,614 oz. against 997,200 oz. during the corresponding period of 1888. In St. Louis and other districts liable to malarial fever quinine is said to be in better demand this year than in any previous season."

THE MANUFACTURE OF QUININE IN INDIA.—It has often been questioned—says the *Madras Mail*—whether a factory for the manufacture of quinine could be profitably started in India, and up to the introduction of the process now in use at Naduvatom, the answer has been in the negative. Now, however, tangible results have been achieved, as the 10 lb. jars of sulphate of quinine, equal in purity to Howard's, which may be seen at the factory, should convince the most sceptical. The next question is, can the drug be produced in paying quantities; or is it—like most of the gold in Wynaad.—undeniably there, but too expensive to produce? ***We are still confronted with the anomaly of stringent orders against private plantations being held by Civil Servants, whilst the collective head of those Civil Servants owns large estates,—which, had they been disposed of when they should have been, would have realised a very large sum, but which are now probably reduced in value 75 per cent by the fall in the price of quinine. It is the duty of Government to foster an industry, but not to compete with it, and prices are so low now that even the possibility of competition is sufficient to deter private enterprise. There would be no fear, were a guarantee of non-competition given by Government, that the price of quinine would be unduly raised, as the imported article would always preserve a fair balance, and, if one factory made a good profit, others would soon start up to share and to compete with it.

DESTRUCTION OF COCONUT BEETLES AT THE STRAITS.—On page 271 we reprint from the *Straits Times* an article on the draft bill for the destruction of coconut beetles in the Straits Settlements. Our contemporary entirely approves of this bill, but in a footnote to the extract we point out some serious objections to the measure, and express a doubt as to its receiving the sanction of the home Government. We also give the remarks of the *Pinang Gazette* and the *Straits Independent* on the proposed bill, and it will be seen that, while the former considers legislation on the subject necessary but that the bill needs modifying, the latter paper condemns the measure *in toto*. The editor says:—

It is very much to be regretted that prior to framing Bills of the nature of the one which forms the subject of our remarks, steps are not taken to ascertain the views and opinions entertained by planters and other practical men competent to express an opinion on the subject at issue. He also refers to Ceylon evidently in the following:—

We believe that in all countries where there are coconut trees these beetles do attack the trees to a greater or less extent. There is a British colony, not far away, where there are some of the largest coconut estates in the world; they are owned by Europeans as well as natives, and we know also that they are likewise troubled by these beetles. But we have never heard of any of them having applied to the Government for special legislation to free them from the pest; in fact, we think that if a Bill on the lines proposed here were attempted to be introduced in that colony the natives would rise in open rebellion, because they would sooner sacrifice their own lives rather than allow a single coconut to be cut down. Certainly the bill will have to be considerably modified ere it can be passed.

VANILLA.—The new *Mauritius* crop, which is known to be very short, is now due at Port Louis. At auction to-day only a few tins offered, and were partly sold at high prices.—*Chemist and Druggist*.

THE DWARFED TREES OF JAPAN.—The French are much interested in the dwarf trees shown by the Japanese horticulturists at the Exhibition. There are exhibited Thuias, Pines, and Cedars, said to be 100 to 150 years old, not higher than 18 inches. Hence one can have small forests in flower-pots, and a collection of Fir trees in a balcony. They are puzzled to conceive how these vegetable deformities are produced by patience and labour. Each branch as it shoots is said to be embedded in earth and retained in position by props or supports and bands. The curvature is made at right angles, and the upper part of the branch continues to grow while the other withers and dies. Every time a young sucker or shoot appears it is treated in the same manner. It is by thus stopping the development and forcing the tree to take various contorted forms, that they are able to produce these curious abortions. This has to be continued by several generations of horticulturists, if we are to believe. Whether there is anything to admire in such dwarf trees is a question of taste: but a sight of them explains the fantastic and unnatural forms of the plants which the Japanese produce on their lacquered trays, on their bronzes, and their embroideries.—*Gardeners' Chronicle*.

LIMES OF WESTERN EUROPE.—Mr. C. S. Sargent, in the *Garden and Forest*, says that, "I can find no distinguishing characters in the bark, in the habit of growth, or in the flowers, which in all three species are destitute of the petaloid scales that occur in those of our American species, or in the winter buds of these trees as they are found growing here; but in the leaves and in the fruit they are clearly distinct. The following characters, therefore, may be found useful in enabling cultivators who cannot always readily refer to the old figures to distinguish the different species:—

"CONSPECTUS OF THE SPECIES.

"Leaves pubescent: fruit prominently four-ribbed at maturity. . . . 1. *Tilia platyphyllos*.

"Leaves naked, except in the axils of the principal veins: fruit destitute of wings.

"Leaves ample, the base more or less oblique, green on both surfaces: tufts of hairs pale: shell of the fruit thick and tough. . . . 2. *T. vulgaris*.

"Leaves small, sub-cordate or rounded at the base, pale on the lower surface: tufts of hair, rusty brown: shell of the fruit thin and brittle. . . . 3. *T. ulnifolia*."—*Gardeners' Chronicle*.

EUGENIA JAMBOLINA.—The value of Jambul in cases of diabetes has not so far been conclusively proved, and I therefore give all the information I have been able to secure, in order to enable the profession to form some sort of opinion upon a drug which, if it really performs what is claimed for it, would be hailed as one of the most important additions to recent *Materia Medica*. It will be seen from the reports which follow that in many cases Jambul does certainly appear to have been of benefit, whilst in others it failed entirely. To account for this strange uncertainty in the action is, with our still imperfect knowledge of the chemistry of Jambul seed, somewhat difficult. Some explanation may be looked for by workers in the process of drying the seed, but although this may be a correct view to take, there is the fact that seed taken from one bag received from the East Indies has yielded totally opposite results in the hands of medical men. It is no longer a subject of doubt that Jambul seed has the power to prevent the transformation of starch into saccharine matter, and I am greatly indebted to Dr. T. A. E. Balfour, of the Royal College of Physicians of Edinburgh, and his co-worker, Dr. G. Sims Woodhead, for important evidence on the behaviour of Jambul in the presence of Starch, and also on the results obtained with it in a case of diabetes.—*Christy's "New Commercial Plants and Drugs."*

THE COCONUT BEETLE AT THE STRAITS.

On Saturday we published the text of a Bill which has been drafted with the view of crushing out, or at least greatly mitigating, a pest which has been found dangerous to a considerable Singapore industry. Everywhere in Singapore, but more especially near the shores, are to be seen great plantations of coconut trees, and from the owners of these there has long been complaint of the ravages of certain beetles which are now dignified with the names "oryctes rhinoceros" and "rhynchophorus ferrugineus." The beetles are as deadly as their awful names would imply, and almost since he arrived in Singapore, Mr. Ridley, the Director of Gardens and Forests, has been engaged studying their habits, alike in the coconut plantations and in the laboratory; while from all sides he has been having suggestions as to the origin, cause, and habits of the insects. The result is a Bill which has been drafted by Mr. Bonser from Mr. Ridley's notes, and which will be introduced into the Legislative Council as soon as possible. The theory of the Bill is that the beetle breeds in accumulations of decaying rubbish generally, but particularly in dead or decaying coconut trees, and also now in trees that are not yet dead but which have been successfully attacked by the insect. The Bill therefore provides that the owner of any coconut tree attacked by the beetles shall cut it down and "consume it with fire" which latter, by-the-way, is a troublesome thing to do, for coconut timber does not burn easily. As this compulsory destruction is for the public, as well as for the individual, benefit, the owner, in needy circumstances, may be paid compensation to the amount of five dollars a tree. Further, the Bill sets forth that no person may keep on his premises "dead coconut trees or stumps.....or other accumulations of refuse.....or other matter which would be likely to harbour the said beetle," and it imposes penalties for so doing, and gives the Garden and Forests department power to remove such refuse at the offenders' cost, and to enter on land for such purposes. The rubbish clause, it may be noted, may be used to remove the stuff which is accumulated in certain tanneries, and which is alleged, although of that we are not sure, to be a fruitful breeding place for the coconut beetle. There can be little doubt that this Bill will meet with general approval, even if there be a demand for amendment in detail. In theory it is much the same as the home legislation which is intended to protect animals from certain contagious disease, and from the same legislation the principle of compensation is probably borrowed. No doubt there may be some difficulty in enforcing all its provisions, but that of course is merely a matter of employing an efficient staff. The object to be attained, the stamping out of the coconut beetle, is of importance, and is indeed essential to the profitable continuance of an industry in which a great many deserving people are interested; and we will all be glad to hope that the provisions of the Bill will have the effect desired.—*Straits Times*, August 19th.

[The object sought is very desirable, but we doubt if it can be attained by the heroic legislation proposed, and the sanction of which by the home authorities we doubt. The law is open to the objections that it might be used as a means of oppression, and that, if strictly enforced, the keeping of manure heaps for the fertilization of lands will become impossible.—Ed.]

THE COCONUT BEETLE BILL.

The chief feature of the measure, which has been drafted by the Attorney-General, with, we understand,

the assistance of Mr. Ridley, the head of the Forest Department, is the cutting down and burning of all coconut trees attacked by beetles. We have the authority of a very experienced planter for saying that it is not only quite unnecessary, but also would be absolutely ruinous to adopt such a course. It is quite impossible to keep beetles out of coconut trees altogether. They exist in every plantation, but, with proper care, do little harm. On many large estates coolies are kept for the purpose of catching and destroying these insects; on others the owners contract with the pluckers to examine the trees when collecting the nuts, and destroy the beetles. With these precautions, though beetles are always there, they do little harm. On the other hand there are plantations where little care is taken, and the trees suffer accordingly. Even, however, where plantations are badly attacked, if the owners set resolutely to work destroying the beetles, the trees will soon recover and give as much fruit as ever. This being the case, it would be cruel to enforce the destruction of trees simply because they are attacked. It would mean unnecessary ruin to many. While pointing this out, however, we by no means think that legislation on the subject is unnecessary. Owing to ignorance or some other cause, a vast number of trees are being destroyed by beetles, without any effort on the part of their owners to preserve them; and as these trees become breeding places for beetles, which swarm into and attack the young trees in neighbouring plantations, it is necessary that measures be taken to deal with the owners of plantations who do not attend to them—not for their own good, but for the protection of their neighbours. Badly kept plantations, however, are neither the only, nor the worst, breeding places. The beetles breed principally in manure heaps, chaff thrown out from mills, and such like rubbish. This has been recognized by those who drew the bill, and there is a most useful clause dealing with people who, after receiving notice from the Director of Gardens and Forests to destroy such heaps, still keep them on their premises. We are glad that Government is taking the matter up. It is of great importance to the colony, and particularly to this Settlement, to protect coconut trees from the ravages of beetles; and although the bill is faulty, it is on the right lines.—*Pinang Gazette*.

THE PROPOSED COCONUT TREES PRESERVATION ORDINANCE.

The provisions of the draft Bill published in the *Government Gazette* of the 16th instant for the "Protection" of Coco-nut trees from the "ravages of certain beetles," savour very much the recommendations of our local contemporary for getting rid of hydrophobia, and we are exceedingly sorry to be obliged to comment adversely on the proposed measure, because its provisions are not only drastic and unreasonable, but such as will never secure the end the Bill has in view. By the 2nd section of the proposed Ordinance the "owner or person in charge of every coconut tree which is attacked by the beetles" is required "forthwith to cut down such tree and to consume it with fire so that the beetle and all eggs and larvæ thereof may be totally destroyed." No person at all acquainted with the management of coconut plantations or of trees that are attacked by beetles would make a demand of such an unreasonable and absurd nature. In this Settlement cocoanut plantations are mostly owned by Chinese, and it is naturally to the interest of every such owner to protect his trees not only from the ravages of beetles, but everything else that may affect them injuriously. Hence every proprietor of a coconut plantation provides himself against these drawbacks. In the case of attacks by beetles, the owners either have in their employ a number of men who have made the matter their special study, or engage the services of such as they may require; these men are employed in examining the trees, destroying the beetles as well as their eggs and larvæ, and in stuffing the places attacked with a quantity of salt and earth,

both to prevent the tree from dying and save it from future attacks. If an enquiry were instituted, we feel confident that it would be found that all the owners of coconut plantations invariably employ men of this kind, and that their trees are duly protected from attacks of beetles by the care and attention paid to them by those skilled in getting rid of the vermin. It would be an extreme case, indeed, where they would resort to the necessity of cutting down a tree. Whenever they do so it is simply to get rid of an useless tree, and with the object of protecting others, because the latter are looked after without reference to any injury a single tree may suffer from. Now in the case of these plantations, it would be unjust and unreasonable to require the owners to "forthwith" cut down a tree that may be attacked, because they would be compelled to destroy such a tree, although they might save it if they were not interfered with.

We have said that the obligation imposed by the Act is also absurd. We say so because it does not necessarily follow that by cutting down the tree the destruction of the beetles will be secured. The very act of cutting a tree down will induce the beetles that are on it to fly away to another, upon which they will commence their operations anew; and, as a consequence, every tree on an extensive plantation would have to be cut down without any benefit to anyone, and without the proprietor receiving any compensation, as the owner of an important plantation cannot be considered to be "in needy circumstances."

If there be any neglect in attending to the protection of coconut trees from the inroads of beetles it must be, and, as far as our information goes, it is on the part of the Malays, the aboriginal natives of the place, who own small gardens with coconut, among other trees in them. These people are by nature too apathetic and indifferent to their interests in other respects to care for a few coconut trees. They cannot feel the loss caused by the destruction of a tree or two, so long as they have something else to fall back upon; and so far as they are concerned we believe it will not matter them a whit whether the trees are destroyed by beetles or by the subsequent action of the Government. We cannot, however, understand that either for the protection of these or any others who neglect their plantations by allowing beetles to cause havoc in them with impunity, the owners of all coconut estates who do all that is necessary to protect their interests should be subjected to loss and annoyance by interference with their properties in the way the proposed Ordinance intends to do, either as regards the cutting down of their coconut trees or the removal and destruction of "dead coconut trees or stumps or coconut timber rubbish heaps or other accumulations of dung vegetable refuse," which the owners of such properties might have collected at considerable expense for manuring the trees or other useful or necessary purposes. In one sense laws of this nature may be looked upon as attempts at interfering with the legitimate rights of Her Majesty's subjects.

It is very much to be regretted that prior to framing Bills of the nature of the one which forms the subject of our remarks, steps are not taken to ascertain the views and opinions entertained by planters and other practical men competent to express an opinion on the subject at issue. As regards the proposed Bill under discussion, while we readily accord our Attorney-General and the Head of the Forest Department the possession of all the talent and qualifications which they are reputed to possess, we do not hesitate to say that the Bill would have been framed on other lines altogether if they had condescended to invite an expression of opinion on the part of owners of coconut estates and others who by long experience in the management of their properties are possessed of information. Such a course would have furnished those two gentlemen with most valuable information, of which they were evidently ignorant at the time they framed the Bill. With the present scare for fresh legislation, it would seem as if our law framers had not the time to

make enquiries or that they think it beneath their dignity to be influenced by any other than their own particular views on matters calling for legislation, however uninformed and inexperienced they might themselves be on those matters.—*Straits Independent and Penang Chronicle.*

PAPER MILLS IN INDIA.

The paper Mills industry in India is one of yearly growing importance in the considerable addition it makes to the extent of local manufactures, and the consequently diminished requirements from foreign markets. It is only under the present outlook of the relations of silver that any economic calculations can be projected from any data which can be made to show that the people of this country will need less of the manufactures and productions of other nations owing to enlarged indigenous productions, throwing a large weight in adjusting the balance of trade on silver imports and India Council's drawings.

Paper manufacture by steam machinery was first commenced in India by the late John Marshman at Serampore. Working by a sort of rule-of-thumb process with anything but the most modern machinery—and no scientifically tested process—the highest success scored by the mills was the well-known "Serampore paper." Even that was attained with great difficulty, owing to the effect of climate on the bleaching medium used. After various vicissitudes the mill was broken up, and the King of Burmah became the happy possessor of the machinery, lock, stock, and barrel. There are now nine Paper Mills—five in the Bombay Presidency, two in Bengal, one at Lucknow, and one at Gwalior. Three of these are under private, and the remainder under Joint Stock Association auspices. These mills manufacture blotting, brown, and white cartridges, white country paper, writing and foolscap papers, and colored coarse papers. The materials used are wheat and rice straw, rags, various kinds of grasses, old jute, and hemp rope, or bagging, wood-pulp and waste paper. It is needless to say that the supply of rags is of too precarious a character and limited extent to admit of any extension of the quantity of any of the finer class of papers these mills can manufacture. The invested capital in these mills totals up to nearly £500,000. The largest mill is at Bally, and produces yearly about 3,100 tons of paper. The value of the yearly production of all the mills collectively is ₹29,00,000, and they give employment to about 3,500 people. The sale of the Indian-made paper is yearly increasing, and under more skilled superintendence, and the improved machinery which has recently been imported, the class of paper turned out is of a better quality, and commands a larger sale than hitherto. In the last five years, the value of the paper turned out from the Indian Mills has risen from ₹18,00,000 to ₹24,40,000. There is no apparent effect from the local industry on the value of the imports into India from foreign markets; the expansion of the trade has been very great, and the consumption is now very large. In 1867-68 the value of the paper imports was ₹28,50,000; in 1877-78, ₹30,50,000, and in 1888-89, ₹40,26,921.—*Indian Daily News.*

TOBACCO ENEMY.—Read letter from H. Caine, Esq. Tobacco Expert, dated 13th April 1889. Abstract.—Reporting on the parasite "Bodu" *Phelipæa Indica*. Resolution—dated 3rd June 1889, No. 267. Mr. Caine's report, together with extracts from the correspondence which took place in 1883 and 1884 on the subject will be published in the form of a bulletin for general information. Although no doubt the unfavourable conditions of soil to which Mr. Caine alludes may often predispose tobacco growing on it to attacks of bodu, there can be no doubt that the parasite is propagated by seed, and that it is necessary to remember this in making any suggestions for extirpating the pest. The matter will call for Mr. Caine's further attention when he next visits the Godavari.—*Madras Board of Revenue.*

CHINESE WHITE WAX.

The British Consul at Ichang, in his report for the year 1887, which has only recently appeared, thus speaks of Chinese White or Insect Wax:—"The steamer export of white wax (not bleached bees' wax, but the insect wax produced by the coccus *Pe-la*) has increased greatly. This curious and beautiful substance, though widely used in China, and though known to science, and repeatedly noticed in books on China, seems to be unfamiliar in our home market. Its high price has been against it, but the price has gone down greatly. According to my information the price at Kia-tung-Fu (in Sze-ch'wan, on the Min River, some 700 miles up-river from Ichang) has lately been about 1s. per pound avoirdupois. At Ichang there is at present no wholesale market for the article, but the wholesale cost, as got for local consumption, is stated at about 1s. 3d. per pound. Allowing for duty, freight, commissions, &c., the article might be placed on the home market at about 1s. 6d. per pound. In view of its beauty, hardness, and high melting-point, it might be acceptable in the candle manufacture, to serve as a coating or otherwise. Not knowing whether samples are readily to be got in our country, I think of sending a sample to the Society of Arts in London."

The writer of this report is, perhaps, not aware that the wax has appeared commercially in this country, though only very occasionally.

In Shantung, it seems, especially in the neighbourhood of Lai-yang, where the trees are plentiful, the insects are bred, and the wax produced. The insects are put on in the spring, and the wax is gathered at the end of the summer, after which the insects are collected, and preserved indoors till the following spring. At the Kia-tung-Fu the wax-farmers about the end of April, convey the very prolific female insects from the breeding districts to the wax-district. The journey is performed on foot, and occupies about a fortnight, being performed only at night, as exposure to the heat of the sun would forward the hatching of the eggs, which must not take place till the females have been attached to the trees, which are either those of *Fraxinus chinensis*, or *Ligustrum lucidum*. Six or seven of the insects are wrapped together in a Palm-leaf, and attached to the branches, where they soon give birth to a multitude of young ones, and then die. The young insects swarm over the twigs of the trees, which they puncture in all directions, with the result that they are soon completely incrustated with the white wax. No care is necessary while the insects are on the twigs, as nothing ever touches them, not even ants. About the latter end of August the twigs are cut off, and boiled in water, in which the wax melts and floats on the top. It is afterwards re-melted, and poured into pans where it cools into a translucent, crystalline, somewhat brittle white mass, not unlike spermaceti. The exports of this wax from Shanghai in 1879 amounted to 6,542 piculs.—JOHN R. JACKSON, Museum, Royal Gardens, Kew.—*Gardeners' Chronicle*.

JUTE AND ITS USES.

The development of the Jute industry in this country is one of the most marked in the history of any vegetable fibre. Dundee, as is well known, is the centre of this now flourishing trade, and it has been associated with the jute manufacture since about the year 1822. Jute, as is well known, is the fibre obtained from the stems of *Corchorus capsularis* and *C. olitorius*, belonging to the natural order *Tiliaceæ*, natives of India, where it has for a very long time been used for making rice and sugar-bags. When first introduced into this country it was used for the coarser kind of work, such as sacks, bags, &c., but it was soon shown that the fibre was capable of being converted into fabrics of a very fine appearance, and after being dyed was applicable to carpet weaving. It is still largely used for this purpose, but its use has also been extended in the direction of art tapestries and such-like printed fabrics; and more recently jute has been applied to a large

number of uses, for which hemp has hitherto been in demand. The jute exhibits of Messrs. Cox Bros., of Camperdown Works, Dundee, at the late Glasgow Exhibition gave an excellent idea of the rapid development of the trade, for besides a very great improvement in carpet weaving and sacking, there were shown numerous finely-finished samples of window-cords, ropes, and twines, equal in appearance and finish to those made from the best hemp. Since the exhibition, specimens of these manufactures have been liberally presented to the Kew Museum. A very good idea of the importance of the jute trade may be had from a description of Messrs. Cox's works, from which the following notes have been gathered.

The whole premises, which are built in a most substantial manner, cover an area of 28 acres; a railway runs into the works from the Caledonian line for the direct conveyance of the jute, coal, and other materials; and it is stated that, notwithstanding all modern improvements have been adopted in the machinery, as many as 90 tons of fuel are consumed per day.

The jute fibre arrives packed by hydraulic pressure into bales weighing about 400 lb. each, which are landed from the vessels in the Dundee docks into the railway wagons, and conveyed direct to the works; from here the bales are taken as they are required to a house called the "batching-house," where they are broken up and the qualities assorted. The fibre is then subjected to a mixture of oil and water to facilitate its subsequent treatment. The successive processes of carding, drawing and roving reduce the filaments to certain degrees of fineness, and prepares them for the next process of spinning into yarn. The spinning mills contain over 20,000 spindles, and the weaving sheds 1,000 power-looms. "About 120,000 bales of jute of 400 lb. each are annually used, which is one-eighth of the consumption of the town of Dundee and district, and about one-fourteenth of the total imported into Great Britain, which includes much that finds its way to the Continent. Besides large quantities of every size of yarn sold to the trade, the length of cloth annually produced is from 30,000,000 to 40,000,000 yards. Even a partial enumeration of the woven products of jute manufactured at these works shows how widely the fibre is made to enter into the commercial, agricultural, social, and even personal life of the world." The following are some of the articles enumerated: sacking, tarpaulins, rick covers, sacks, and bags for all purposes, horse blanketing, mattress cloth or bed ticks, furniture cloth, embroidery cloth, matting, hearthrugs, carpets, curtains, table and bed covers, and various other articles, to manufacture which as many as 5,000 hands are employed.—JOHN R. JACKSON, Museum, Royal Gardens Kew.—*Gardeners' Chronicle*.

DRUG CULTIVATION IN JAMAICA.

The director of the Jamaica public gardens and plantations in his annual report for 1888, which has just been issued, observes that in cool places, under the shade of bananas, *Nutmegs* thrive well in Jamaica. The trees bear heavy crops, but the fruit is small. *Cacao* does remarkably well along with the nutmegs, and the trees also bear heavy crops of fine pods. A sample of cacao was cured at the Hope gardens in May last, and forwarded to Mr. Bravo, chocolate manufacturer, Kingston, who pronounced it equal to cacao which he imports from Venezuela. Mr. Bravo manufactured the sample into chocolate and exhibited it at the Kingston flower and horticultural show held in June, and competent judges declared it not inferior to the best chocolate imported from France. The sample of cacao was cured strictly in accordance with the instructions given in Mr. Morris's pamphlet on "Cacao—How to grow and how to cure it." Only one half of the mass, however, was "clayed," and Mr. Bravo is of opinion that the process is not at all necessary, the unclayed portion of our sample being in every way equal to the "clayed."

Cinnamon grows luxuriantly at Hope. The young trees were raised from seeds obtained from plants of one of the best varieties brought from Ceylon,

therefore they can be recommended. It appears, like the mango, there are numerous varieties of Cinnamon many of which are of little value. The *Kola nut* grows fairly well, but has not yet fruited. The gardens supply seeds, when in season, for persons wishing to take up the cultivation of this plant. *Cardamoms* are not a success at the Hope gardens, the plant thriving best in moist, shady situations from 1,500 to 3,000 feet above sea level; but *Vanilla*, as might be expected, grows and flowers freely.

The *Tea* plantations have received careful attention. A small amount of tea manufactured at the gardens was submitted to a firm of tea brokers in London, whose report was of a very favourable character. There are three areas under cultivation, one at Latimer, where the plant is perfectly naturalised, one at Upper Buzza, and one below the garden. In future it is proposed only to cultivate the latter area to supply from time to time leaf for experimental manufacture. The other plantations will supply a sufficient number of plants for those who wish to experiment with the growth in different parts of the island. From the Blue Mountain ridge down almost to the sea coast on the north side the conditions are favourable to the growth of tea; extensive planting is not recommended anywhere in Jamaica, so long as labour is scarce. Tea is made only from the very young leaves, which burst out all over the bush once in two, three, or four weeks, according to the season. If these leaves are not picked at once they grow too large for manufacture. It is thus necessary on a tea plantation to have an abundance of cheap labour available at an hour's notice. Possibly the severe restrictions that are being placed on immigration in the United States and elsewhere may lead to a portion of the stream being diverted to Jamaica. Certainly the tea industry, which has grown to such enormous proportions in Ceylon, is impossible in Jamaica in the present state of the labour market, though all other conditions are extremely favourable. The plant has become naturalised, springing spontaneously from self-sown seed; and the manufactured leaf, which received a gold medal at the Philadelphia Exhibition in 1877, still maintains its reputation, being quoted at a much higher price than the Ceylon tea.—*Chemist and Druggist.*

SOUTHERN INDIAN DIAMONDS.

The Annual Report of the Geological Survey of India and of the Geological Museum, Calcutta, for last year, has just been issued, and under the heading Peninsular India there is a brief survey of the Madras diamond fields in the Bellary and Kurnool Districts, of the Madras gold-bearing rocks, and of the coal fields in the Nizam's Dominions. Dr. King, Director-General of the Survey of India, in his remarks about the diamond fields, says that during one of his recent tours he again visited them, more especially with a view to the elucidation of the occurrence of diamonds at Wajra Karur, the district where the Madras Presidency Diamond Company is at present conducting mining operations, but where, as Dr. King says, no outlier or remnant of the recognised diamond bearing beds (Banaganpillis of the Kurnool series) exist. The object, on the part of Dr. King and his associates, was the discovery of the original source or parent rock for diamonds; for it "gradually became evident that the gems known to occur in the peculiar gravelly shales near the base of the Banaganpillis sandstones may really be only pebbles just as much as the water-worn districts with which they are associated." Dr. King says he hopes that such an original source is about to be discovered by private exploitation an allusion probably to the work of the Madras Company. This Company is working steadily on. Small stones have been discovered in some numbers, but the larger and more valuable stones still remain hidden. Mr. Bruce Foote is apparently of opinion that diamonds do not exist in the rock about this part and that being found only in the surface soil, they are only "part, of the superficial *débris* having been derived from a long disappeared upper

portion of the same neck rock which had passed through some carbonaceous deposit which, in past ages, has also been worn off the face of the country. The neck above-mentioned is one of igneous rock, said to occur among the gneisses which bears some resemblance to the kimberlite (*var. peredilite*) or blue (miner's term, not a blue clay) of the "Cape diamond fields," in which some of the Wajra Karur diamonds are said to have been found. Dr. King however prefers as yet to consider that these diamonds are from the *débris* of outliers of Banaganpillis sandstone which once existed near or at Wajra Karur. But he concludes by saying that in the meantime no diamonds have been detected in the specimens of "neck" rock which have been treated by himself and his colleagues.

Wajra Karur is about sixteen miles distant from Banaganpilli, and the diamond-bearing strata covers the old Cuddapah rocks as with a thin skin. That diamonds were found in this locality in some abundance in former days appears from the fact that many Guzerat merchants dwelt here, and carried on a trade in diamonds, and that after the district was ceded thirty diamond mines were in operation. As however, between 1803 and 1838, the annual average revenue derived from the working of the mines was only Rs. 600, the owners allowed their leases to gradually expire. During the above period also only seven diamonds weighing more than a pagoda each were found. At Banaganpilli, in Kurnool, Dr. King made an inspection several years ago, but saw no diamonds *in situ* nor did he hear of any diamonds being found for four or five days at a time. The diamonds which were brought for his inspection, and which were said to have been extracted from the mines at Banaganpilli, were "disappointing on account of their minuteness, flaws, and dirty colour." No stones of a greater value than Rs. 400 were found there. Dr. King was able to trace the extension of the diamond-bearing stratum for several miles to the west beyond the region wherein it was worked. There are several other places in the Kurnool, Kistna, and Godavery Districts where diamond mines have been worked, notably at Raolconda, Kollur, Malavilly, Bhadrachellum, &c. At Kollur, in 1669, is supposed to have been discovered the Great Mogul diamond, originally of 289 carats belonging to the Emperor Aurungzebe, and subsequently to Shah Jehan. It has also been suggested by some native writers that diamond known as the Kohi-noor, or 'mountain of light' was so named in consequence of Kollur being the place where it was found. This famous gem was possessed in turn by Shan Jehan, Nadir Shah, Shah Soojah, Runjeet Singh and Dhuleep Singh and it was confiscated by the East India Company in 1849. It was sent to England in the charge of Colonel Mackeson and Captain Ramsay and presented, on the 3rd July, 1850, at a levee, by the Chairman and Deputy Chairman of the Company, to Queen Victoria from whom it is now claimed by the "proud and implacable foe of England."—*Madras Mail.*

THE POOR PROSPECTS OF COFFEE IN BRAZIL.

As Brazil is India's foremost rival in the coffee trade, any information regarding the crop prospects in that country ought to interest coffee planters in South India and Ceylon. Some fourteen months ago we published some extracts from a home paper containing a forecast of the season's coffee prospects, which had been compiled by Messrs. Lacerda and Co., of Havre. As this firm's views seem to have been verified to a remarkable extent, it is desirable to show what the same firm thinks of the coming season. This we are enabled to do thanks to a long communication with which we have been favoured, together with statistics on the coffee trade issued by some of the most eminent firms in Europe. For last year it was estimated that the outturn of Brazilian coffee would amount to 4½ million bags of Rio de Janeiro

and 2½ million bags of Santos, but the estimate for Rio de Janeiro was slightly too high, and from the latest information received it appears that the total for the two crops amounts to 6½ million bags. In the two coffee districts of Sao Paulo and Rio de Janeiro it has been found from long experience that the crop-bearing capacities of the trees differ considerably. In Sao Paulo trees begin to bear when they are four or five years old. At first the crop is very small, but after six years the crops are heavier, and between the fourth and sixteenth year each branch bears a crop every year. The crop is regularly good in one year, and middling the next; but from the sixteenth to the twenty-fifth year this regularity changes; the crop is good one year, little or nothing the next, and the following year middling, and then again follows a good crop, a bad crop, and middling crop in regular succession. The order changes again from the twenty-fifth to the thirty-fifth year. The tree takes longer to get into full bearing, and the crops are less regular. After the thirty-fifth year the only trees that bear are those that are planted in the very best soil. Such trees produce a poor crop, and it certainly does not pay to work them, now that slavery has been abolished, and all labour has to be paid for. If the soil is not of the first quality the trees will not bear after the twenty-fifth year. In Sao Paulo the planters use little or no manure, and the soil is gradually becoming impoverished, which is beginning to tell on the crops more severely every year. On the plantations in the Rio de Janeiro province the trees begin to bear later than in Sao Paulo, nor do they hold out so long. The estates are amongst the mountains where the soil is less rich, and where the trees have in consequence to be renewed more often. With these facts as to the order of crops before them it is easy for those interested in the Brazilian trade to estimate pretty accurately what the out-turn should be in any year. Unless frost, or some other contretemps intervenes, crops are produced in the order mentioned above, and on these data the out-turn for the year 1889-90 has been estimated, and will be found to be 4 million bags, as compared with 6½ millions last year. But even this low figure will be found probably too high, as a season of drought occurred at the beginning of the year just when rain was most needed.

The question of labour has become a most pressing one to Brazilian planters. Even with slaves the planters had found it hard enough to make things pay since 1881, when prices were so much reduced. But slavery was abolished last year, and the cost of working has as a natural consequence considerably increased. In Sao Paulo a system of labour recruitment was quickly organised before matters came to a crisis, but in the Rio de Janeiro province labour has not been procured fast enough to take the place of the liberated slaves. The consequence is the planters are all at sixes and sevens, and, far from replanting tracts where the trees are out of bearing, sufficient labour cannot even be found to carry on the work required for the trees that are bearing full crops. Things are gradually righting themselves, however, and replanting will soon commence, but as such trees will not come into bearing for another five or six years, no very great augmentation of out-turn may be expected before then. In fact a considerable decrease may be looked for, because the number of trees that are getting too old to bear crops is very considerable, owing to the extensive planting that took place between twenty-five and thirty years ago. This ought to be good news for Indian coffee planters, and it must lead them to hope that the recent bad times in coffee planting are not likely to recur for some years at all events. By a series of calculations, which are too detailed to reproduce here, it has been estimated that the total amount of coffee from all sources which will be placed on the world's market from March, 1st 1889, to July 1st, 1890, will be 13½ million bags. From statistics furnished by several eminent continental firms in the coffee trade, it appears that the average annual consumption for the last six years amount to 10½ million bags, so that

if these figures are applied to the 16 months from March 1st, 1889 to July 1st, 1890, considerably more than 14 million bags will be required. But only 13½ million bags will be put on the market during that period, so that the supply will not quite meet the demand; the natural consequence will be enhancement of prices. But besides this, the average demand ought in the ordinary course of events to be somewhat higher this year, because of the abnormal tightness in the market last year. Buyers were keeping back and would only buy what they actually required. They were waiting for lower prices, and kept up the supply by indenting on reserve stocks. These reserve stocks have now pretty well been exhausted with the result that they have had to be replenished by buying in the open market. This is the cause of the recent high prices. By examining carefully the present and prospective state of the coffee trade one arrives at the conclusion that high prices will probably rule for a long time and without interruption. The low prices that have ruled during these last few years have had their effect in reducing the out-turn in all parts of the world, so that those planters who have held on are likely soon to reap the reward for their patience. Java and Ceylon which formerly were wont to produce a large amount of coffee, have not had the patience to wait for the time when the reaction from the too keen competition would set in, and in every coffee-producing country the estates that have been abandoned, or planted with other commodities, such as tea, are almost innumerable. The days of unremunerative prices for coffee are evidently past and a revival of coffee planting enterprise in this country during the next few years may be expected.—*Madras Mail.*

VEGETATION ON THE LIME SOILS OF THE MEDITERRANEAN.

I believe that it is an acknowledged fact that a lime soil contains in abundance the mineral constituents required by most plants, and that with sunshine and water it may be considered a naturally fertile soil, even in the partial or total absence of manure, natural or artificial. Such is, undoubtedly, the case in the Mediterranean area, where most of the mountains and rocks—indeed, nearly all the principal geological formations—are formed by secondary limestones.

Throughout this region—the Genoese Riviera—on the islands, and on the shores of Mediterranean, manure is very little used except in the vicinity of towns, for a very good reason: it is both rare and very expensive. Compared with the northern parts of Europe, there are very few cattle or domestic animals in the sparsely populated regions, and artificial manures may be said to be all but practically unknown. The peasantry live all but exclusively on corn or Maize flour, Beans, Chestnuts, farinaceous Dates, Olive oil, fruit and wine, consuming very little animal food, often none at all. In this all but vegetable diet they find all the elements of nutrition required both to produce heat and force, and to repair the wear and tear of the organic machinery, the body; carbon, nitrates, its mineral constituents, &c. These food habits, producing vigorous, strong, healthy organisations, prove that the theory that attributes the generation of heat and force in man wholly to nitrogenous food in the shape of animal substances is a mistake. Heat and force are principally generated from the carbon of the food, as in a railway engine; animal food does little else but repair the wear and tear of the machinery in the body, and should not be taken in excess, as it generally is with the well-to-do.

In these southern regions, exposure to the atmosphere, and to the intense heat and light of the sun seem to renovate the soil, to renew its vitality and fertility to a considerable extent, and to enable it (provided the supply of water be abundant) to reproduce the plants specially suited to lime soils. The requirements of such plants, however, are not very great, as evidenced by the history of the Ivy, which grow with vigour everywhere on old mortar of walls with-

out soil; on these lime soils it is most luxuriant, and has repeatedly continued to grow with me on walls and rocks when the earth-roots had been completely severed. The large-leaved African variety which I brought from Algeria, where I found it flourishing in the ravines in the sunshine, grows with marvellous vigour; in about eight years it entirely covered two sides of my old tower, 60 feet high, and I was obliged at last to destroy it, lest it should actually eat up the tower, the old mortar of which supplied it with sufficient nourishment to make it all but independent of its roots. I began by cutting it away up to the first story; but this sharp practice did not seem to make much difference, it went on living and flourishing as a parasite; so I ruthlessly, but to my very great regret, destroyed it entirely.

I do not mean to convey the idea that the value of manure is not fully recognised in the Mediterranean areas as a means of renovating exhausted soils, and of securing and increasing cereal or other crops; indeed, manure is preserved, both animal and human, as preciously as in China. Except in large towns, frequented by strangers, there are no wasteful water-closets, and all that comes from the soil is conscientiously returned to it. In that respect, with all our vaunted civilisation, we are really behind the Mediterranean and Chinese peasantry, although it must be acknowledged that their mode of dealing with this source of agricultural riches is objectionable to our fastidious tastes. The disinfection by earth as taught by Moses, and by Mr. Moule—a Chinese missionary, I believe—is still all but unknown with us, although generally practised in the Mediterranean area, in a way. The practical fact is, that I am growing a number of plants in my lime-soil on the Riviera with marvellous success without any manure at all, and that they seem to get on without it as well as the Ivy. This fact may throw some light on the traditional Mediterranean agriculture, showing, as it does, that heat, sunshine, and water do more there than they do in the north to prevent and repair soil exhaustion.

My garden consists of about 7 acres of rocks, precipices, terraces, all but overhanging the Mediterranean, fully exposed to the southern sun, and protected by high mountains from the north-east and north-west. There is very little vegetable soil of any kind, and what there is, is principally composed of the break-up of the limestone rocks, under the influence of the sun, of the spring and autumn tropical rains, and of atmospheric influences generally. Although heavy rains fall in the spring and autumn—some 25 inches on an average, which is more than the average rainfall of Middlesex or Surrey, as it falls tropically—that is rapidly, in sheets, mostly for a few hours only at a time; and as it seldom rains at all from April until October, the climate, like that of Mexico, Australia, and the Cape, is a dry one. Water in such a locality is deficient, often absent. To remedy this deficiency, following the custom of the country, I have built for storage fourteen tanks or reservoirs. Moreover, I have bought for five hours a week, in summer, the privilege of using a permanent spring, which comes out of the rocks in a neighbouring ravine, and gives life to the village and territory of Grimaldi, in which I am located.

This spring belongs, during nine months of the year, by mediæval prescription, to the owners of some olive mills, where the peasant proprietors have their olives crushed and the oil extracted. During the three summer months, July, August, and September, the spring is divided in hours, every week, among the landowners, and is held by them as a property. Land being valueless for sale unless water goes with it, my neighbours took advantage of my ignorance of this fact to sell me land without the water, so I have had to purchase the water separately from others. The quantity which this spring gives me every week—about 50 cubic metres or yards—in the summer, during the five hours each week, is quite insufficient for my wants; but the fact of my being a co-proprietor gives me a hold on the spring during the winter months, if not wanted for the olive mills. I am the only one who waters after heavy rain in order to water the rocks, as I tell my neighbours; so

I manage to repeatedly deluge the place and the terraces and rocks during the winter, and to fill all my tanks, containing some 700 cubic metres, before the summer season begins. Thus, on my system of deep watering, I am radically changing and fertilising the entire property, making an oasis of it. I may add, that I have had a luminous irrigation idea. There is a high road between me and the sea, a steep ascent, which becomes a torrent-bed in heavy rains. I have obtained permission from the authorities to place a small dam on the gutter, which is on my side of the road, and carries the rain-water to the sea; as also to make a culvert under the boundary wall. By this means, when it rains heavily, I get a regular rivulet of water from the road into the lower part of the property, an abandoned quarry, which I am rapidly changing into a garden or forest of Cypresses. The lime-loving Cypresses which I have planted there, in a mere rubble of loose stones, are growing like Asparagus: *Cypripedium excelsum*, *C. elegans*, *C. argentea*, *C. Lambertiana*, *C. macrocarpa*, *C. penula*, and last, but not least, the lovely *Pinus C. canariensis*. I am very proud of having thus introduced "a Nile," with its cataracts, and soil-loaded water into my quarry of stone rubble. Without this irrigation it would never have grown anything but Aloes and Agaves, and now it is fast becoming a small tropical forest, bidding fair to rivalise the old quarry of Latomia at Syracuse in Sicily: *parva componere magnis!* I expect to grow many plants there which do not succeed on the rock soil, and to enlarge the area of Rose culture, and that without manure.

The Roses I named (May 4) as succeeding well were the Banksias, the Bengals, some Teas, such as Safran, Madame Falcot, Gloire de Dijon, Ohromatel, Maréchal Niel, Fortune's Yellow, do perfectly without manure. Indeed, I never give them any at all, and they bloom luxuriantly every year, producing flowers fit for a flower show. I have several Gloire de Dijon plants, ten or more years old, at the bottom of a half-sheltered moist rock, and also of a sun-exposed wall, which are covered every year with splendid blossoms in autumn and in spring, flowering indeed, but sparsely, all winter. These are grown in the lime soil without manure, never having had an ounce since they were planted. We merely renew the old wood occasionally by pruning out old woody stems, and letting new grow, which they do to a height of 10 or 12 feet. The flowers grow on the new shoots 3, 4, or 5 feet long, like garlands, a very beautiful sight. Really the originator of the Gloire de Dijon ought to be made a baronet and have a pension for life. I believe that it is the most vigorously constituted Rose growing. It seems to succeed everywhere in all climates, and apparently in all weathers. I have seen it flourishing everywhere out-of-doors from the north of England to the Mediterranean.

I have, I may mention, a large bed of Safrano, Falcot, Nabonnaud, and Bengals, some twelve years old; about 30 feet long by 14 broad. The plants are all old plants, which have never had a handful of manure since they were planted. The soil is merely roughly dug up and left loose twice a year, in spring after they have flowered, and in autumn after their rest from heat before the rains. They flower magnificently twice a year in autumn and in spring. Just now the bed is a mass of bloom, all but concealing the foliage. In September, after their rest, my gardener prunes them down to about two or three feet from the ground, cutting into the one, two, or three years' wood, according to size and direction. The Banksias, single and double; the Fortune, yellow; the General Lamarque, which all give in spring a perfect river of branches and bloom, never receive an ounce of manure from year's end to year's end. The latter two are scarcely pruned. Under such circumstances it would really be a waste to manure, where manure is so costly and so difficult to obtain.

I tried an experiment last autumn with a bed of three year Boubrinski, a very sweet red Tea, which flowers all winter with us, and is much esteemed. One-third were left alone, the second third had their roots pruned all round, and manure added in the circular trench made for that purpose. The other third

were lifted bodily, root pruned, as advised by some Rosarians, and replanted in a mixture of manure and leaf mould after eight months' growth. I find the Roses left alone, without trenching or manure, by far the most vigorous; those trenched and manured, the next best; and those taken up and replanted in rich soil the worst as regards both growth and flower. The month of May has been unusually rainy and moist, and our Roses have been flowering luxuriantly. For the last few days heat has appeared, max 74°, min. 60°, sky hard blue, sun burning. Most of the Roses are withering. Usually the withering of the Roses from heat occurs by the 10th of May, when we feel it time to depart for pastures new.

We have an economical but very useful plan of using manure; a handful or more is placed at the bottom of the hole where the plant is to be placed, and the roots of the latter spread on it. I recollect on one occasion, Dr. Hogg paying me a visit, and being surprised with the luxuriance of a plant in flower. He asked me to allow my gardener to dig it up, and we found the roots clinging to and all round the manure thus placed, forming, indeed, a ball with it. Thus was its luxuriance accounted for in an apparently poor soil, I recollect Dr. Hogg being also much struck with the extreme vividness of the colour of the flowers, which he attributed to the intensity of the sunlight—no doubt the true explication. Photographers say that the light is four times as intense at Nice, at midday, as it is in Paris.

Under these local conditions, the difficulty of obtaining vegetable mould and manure, and the unmitigated lime character of the soil, I am gradually limiting outdoor cultivation to lime-loving plants, eliminating such as do not do well in it without any alien element. My notion of a garden is for everything to succeed, to be vigorous, healthy, happy. I have been too much saddened throughout my professional career by invalidism and bad constitutions to stand them in the garden. All that does not thrive with me is rooted up, and made away with. On another occasion I shall have something to say about some plants, such as the *Linum trygynum*, the *Russelia juncea*, &c., which must be lime plants from the marvellous way in which they flourish with me.

In conclusion, I would add that gardening on these sunny lime rocks overhanging the Mediterranean is intensely interesting. I have a small staff of local helpmates, into whom I have instilled an interest into all we do: so I and my men, we ramble about the rocks, make tanks, build walls (no longer in mortar, but in loose stones), dig and delve round the old tower, looking for the treasures no doubt buried somewhere, hundreds of years ago, by some mediæval Italian freebooting Captain Kidd, pirate by sea, robber by land, who made the tower his stronghold. We have not yet found the treasure, but, like the husbandman in *Æsop's Fables*, we fertilise the land. At the time of the earthquake, a great facing of rock on a mountain 1,000 feet above me fell off with a great crash, tumbling into the ravine below, and revealing a cavern as large as a chapel, in the bowels of the mountain. There are many such caverns up and down in the rocks. So now we are blasting away, in likely directions, hoping to find *Sinbad the Sailor's* cavern, if not full of diamonds, at least of stalactites, and perhaps of *Capitulus veneris*, our commonest Fern, should light penetrate.—HENRY BENNET, M. D., Torre di Grimaldi, Ventimiglia, Italy, June 1.—*Gardeners' Chronicle*.

THE WATER REQUIRED FOR RICE CULTIVATION.

What is the quantity of water required excluding absorption and evaporation, but including rainfall, to produce the best results in rice cultivation in India? Considering the enormous irrigated area in this country, and especially that under rice, the question is one of great importance. It will be hardly credited, however, that it cannot be answered with any pretence to accuracy. The engineer, it is true, is guided

by the more or less empirical rule that two cubic yards per hour per acre are required, exclusive of the rain falling on the area irrigated. The rule has not been deduced from scientifically conducted experiments; the cubic yards are supposed to be the average quantity that the cultivator will draw when left alone, from his source of supply, whether tank or river channel. In fact, at times he uses a great deal more than that quantity, and when the supply falls low, a great deal less. Observations made from time to time have shewn that the amount varies from one to four cubic yards per hour per acre. If one cubic yard is sufficient, it is manifest that with four cubic yards, there must be enormous waste, and this in a thirsty country were every cubic yard worth its weight in silver. The ordinary reader will appreciate the difference more readily when we state that for three months' crops on 10,000 acres a provision of over 86 millions of cubic yards would have to be made at the higher limit; at the lower 22 millions only. For a six months' crops the quantities would be 144 millions, and 36 millions, respectively, or, in other words, if one cubic yard per hour per acre is sufficient to produce a fair average crop of rice, 144 millions of cubic yards of water would be sufficient to irrigate 40,000 acres in the place of 10,000 acres at the higher rate. The importance then of the question will not be contested. We are aware that experiments have been made under the orders of Government on several occasions, but they have not been scientifically nor continuously conducted, and they have been far too few in number. Deductions made from a few ill-devised experiments are worse than useless for they tend rather to mislead than to enlighten. Besides they have been entrusted to some engineer constantly on the move, whose attention could not therefore be continuously given to them. The question is one for the agricultural chemist rather than for the engineer. The rôle of the latter should be confined to the designing and making the works necessary for the accurate measurement and distribution of the water required for the experiments; otherwise he should have nothing to do with them.

Hitherto experiments made in India have erred in several directions. The chemistry of the subject has been much neglected. No analyses have been made of the soils of the plots experimented on nor of the manures used, nor of the water supplied; these are serious omissions, as without the knowledge such analyses give, it is impossible to say how much, and what manure should be used. In fact an analysis of the soil and of the water and its contained slit would often indicate that manure was unnecessary, as the water carries with it all the nutrient substances either in suspension or solution, required for the growth of the plant. In parts of Normandy where meadows are irrigated, it is found when the supply is large rising sometimes to what appears to us here in India the enormous quantity of 200 litres per second per hectare, or 400 cubic yards per hour per acre, no manure is necessary; when, however, the supply is small or deficient, the quantity of manure required increases as the water supply decreases. In the south of France irrigated land has to be very heavily manured, as the supply is often not more than 2 cubic yards per hour per acre. French experiments have established that the fertilising power of water depends upon the volume of water used, within a certain maximum limit of course; and that knowing the chemical composition of the water, especially the quantities of nitrogen and phosphoric acid held in solution, and the volume of water available, and comparing these with the weight and chemical composition of the gathered crops, a balance may be struck, and the exact amount of manure required fixed in each case. But experiments have made no use for further irrigation of the surplus water run off the experimental blots. A first irrigation,—we again turn to the French experiments,—absorbs about 30 per cent of the nitrogen and phosphoric acid in solution, so that the water run off is not so rich as it was, but is still rich enough to be used for further irrigation. What we want to know then is, how much surplus flows

off after a first irrigation, and what further area it can usefully irrigate before being finally discharged or absorbed.

That the irrigating duty of this surplus is often very great in this country is shown by the great differences that exist between the areas irrigated per square mile of drainage basin of purely rain-fed tanks which are situated close together, and subject therefore to the same yearly rainfall. The areas irrigated per square mile vary from 20 to 100 acres. Some part of this great difference may be explained by the fact that the larger and the deeper the tank the greater will be the area per square mile of drainage basin proportionately irrigated under it, but probably much of the difference is due to the greater use made in some cases than in others, of surplus water flowing off fields after first and second irrigations for watering fields on a lower level. In Tanjore, the lower we go down in the Delta the less is the out-turn per acre of cultivation. It would be interesting to ascertain how much of this is due to the poorer soils found towards the coast, and how much to the fact that the water supplied has been already used in irrigation in the higher parts of the Delta, and is therefore less rich in nutritive qualities. It is known for instance that water charged with carbonic acid—as water always is when it has been used once or twice in irrigation—does not part so readily as unused water, with the nitrogen held in solution. All this goes to support the opinion already expressed that the question to be solved is one for the agricultural chemist rather than for the engineer, unless indeed the latter happens also to be a qualified chemist, a combination not likely to be found. Experiments have erred in making no distinction between the methods of irrigation adopted in this country. In one method the field is submerged, that is, a basin is formed, and the water, to a depth of 3 to 6 inches, is impounded therein, and only renewed when it has been nearly absorbed and evaporated. In another a continuous stream of water is kept up, and the plant continually comes into contact with fresh supplies of water, and therefore finds more food to assimilate. It has been found in France that the former method only requires one-fifteenth of the water required in the second. Although this proportion, on account of the greater evaporation, would not be so great in India, yet the forced adoption of the method of submersion in times of scarcity and in bad years might lead to the saving of large areas of valuable crops at critical periods. Another point which has not received proper attention is the degree of permeability of soils experimented on. The more permeable the soil, the greater the consumption of water. In the Vosges where the supply of water provided for the irrigated areas is always great in granitic soils, which are of a very absorbent nature as much as 102 cubic yards per hour per acre are consumed, whilst for non-absorbent soils the supply falls to 40 cubic yards.

The solution of the question then which we set out by asking is one of the utmost importance to the engineer who has to design and carry out works of storage and distribution to the land owner and cultivator whose interest it is to get out of the land without exhausting it as much as it will produce; and, on grounds of health to all those who have to live near or surrounded by rice fields. Nadult de Buffon in his valuable work on the Italian irrigation system cites two cases tending so shew that when the water supply is abundant and sufficient rice fields cease to throw off miasma, and therefore to affect injuriously the health of those living in their neighbourhood. We cite one only of these cases. In Java before the construction of the dam across the Poorang, near the town of Somabaga the supply to the surface irrigated was not more than 408 cubic yards per hour per acre; fever and malaria were then prevalent. But immediately the volume of water was increased by the action of the dam to 612 cubic yards, all sickness disappeared. It will be observed that these quantities are greater than are supposed to be required in India. The Government, then, would do well to undertake the kind of experiments necessary

to solve the question we have raised, exhaustively and conclusively. We have only been able to indicate a few of the omissions of the past, but we have said enough to shew that further experiments are highly desirable. Before the experiments are commenced, rules for the guidance of those in charge of them should be carefully drawn up, both to prevent the repetition of mistakes, and to allow of practical deductions being made from facts that may be established. The record of experiments made by French and Italian Engineers might be usefully taken as a guide to the way in which such experiments should be conducted.—*Madras Mail*.

CEDAR PENCILS.

THE manufacture of Red Cedar pencil-wood has for years been almost exclusively confined to Florida, where this tree (*Juniperus Virginiana*), grows to a large size and in great perfection. The business has been in the hands of a large foreign house, which supplies a good part of the world with lead-pencils, and has been profitable. Large Cedar timber, straight grained, and of a suitable quality for pencil-stuff, has become scarce in Florida, along the streams on the west coast, where the best was found; and factories are springing up in different parts of the south, especially in Alabama, where, at Gurley, sawing pencil-stuff is already a considerable industry. The best Red Cedar, however, now left will be found near the Red River, in Texas, and in the Indian Territory, where this tree attains a greater size than it reaches in Florida, while the quality of the lumber is not, probably, in any way inferior.

The world has become so accustomed to using pencils made of Red Cedar, that it will not readily adapt itself to any others. The supply of this lumber of suitable quality, however, is not large in proportion to the demand, and cannot hold out many years longer.

The Red Cedar is the most widely distributed of North American Conifers, and in some parts of the country it is one of the most common trees; but it is in a few favoured localities only that it grows in a way to produce the straight-grained material essential for pencil-making.

The distillation of oil of Cedar, for which there is now a large commercial demand, from the sawdust and other refuse, has been profitable in the pencil-mills at Cedar Keys in Florida, and might be carried on to advantage in other parts of the country. It can be made, of course, from wood of the poorest quality.—*Garden and Forest*.

TEA AND OTHER MACHINERY.

THE BLACKSTONE ROLLER.—Facts are very stubborn things, and those to which Messrs. W. H. Davies call our attention in their important letter in another column afford irrefragable proof of the capability of the 'Blackstone' roller. We are particularly glad to see this testimony, because we heard quite lately of a case in which the machine was complained of. As we have had a good deal of experience of machinery of many kinds we have found that machines are themselves sometimes very stubborn things.

We call to mind the case in our own experience of a huge machine which was supplied to an eminent engineering firm who, after prolonged trial, declared it to be a failure. As it had already been fully tested before it left the manufactory, it was certain that the fault was in the treatment it had been subjected to. Therefore a foreman was sent from the factory to see what was the matter. Before attempting to work the machine, the emissary examined it carefully, and found that it was very slightly off the level. Adjusting it carefully in this respect, and having satisfied himself that it was otherwise in order, he set it to work and proved it to be altogether perfectly satisfactory both to himself and to the purchasers. The fault was not in the machine, nor in its construction,

but the slight error of level caused the beautifully fitted parts to lock, and thus prevented its working. On such seeming trifles the success of a machine may often depend. We are further reminded that on a recent visit to a tea factory we were informed that the Fairbank weighing machines were not reliable. As this was a most unexpected result we endeavoured to ascertain the cause, and soon found that the machine was being used on a table considerably out of the level which of course interfered with the due working of the mechanism. With regard to the Blackstone roller, of which we ourselves have very little knowledge, we can only remind those of our friends the planters who may happen to possess it that they should consult the maker with regard to any difficulty they find in the working of it.—“Ceylon Independent.”

LAUREL-NUT OIL.

BY DAVID HOOPER.

The Alexandrian laurel (*Calophyllum Inophyllum*, L.) is distributed throughout India and Malaya, and is especially abundant on the western coast and in the native state of Travancore. The Hindustani name of the tree is Sultan Champa, the Tamil and Malayalam name is Punnai. Its thick green and glossy leaves resemble those of a laurel, but the tree is far removed from this family of plants, as it is really a Guttifer, belonging to the natural order Clusiaceæ. The fruit is about the size of a bantam's egg when ripe, and of a greenish yellow colour; when dry it is brown or black and has a hard wrinkled surface. The seed, consisting of two white closely united hemispherical cotyledons, loses in drying 30 per cent. of water, and the dried seed yields 68 per cent. of fixed oils. This oil is largely used for burning, and is occasionally used for making varnishes and soap. In medicine the oil is employed either alone or mixed with more powerful remedies as a liniment for rheumatism, and is applied to ringworm and various skin eruptions. The tariff valuation of laurel-nuts in Travancore is R7 per cwt. and the oil R8 as against coconut oil R14 per cwt. The value of the exports of laurel-nut oil from Travancore during the past five years has been as follows:—1882-83, R74,314; 1883-84, R68,767; 1884-85, R48,997; 1885-86, R78,845; 1886-87 R57,148. In 1886-87 63 cwt was exported from Alleppey. Dr. Watt says that although this oil cannot compete with castor oil for industrial purposes in the Calcutta market, it fetches about four times the Calcutta price of castor oil in Burma.* In the Colonial and Indian Exhibition † held in London in 1886, this oil was shown from India, Ceylon, Straits Settlements, Queensland and Fiji. It is known out of India as domba, dilo or ndilo oil.

Laurel-nut oil is greenish-yellow, bitter and aromatic, but it has not been investigated chemically. Lépine found a sample to have the sp. gr. 0.942, and to solidify at † 5°. During a recent visit to Travancore, I found a large trade being done in the nuts and oil of *Calophyllum Inophyllum* in the village of Neyoor, about sixteen miles from Cape Comorin, and here I purchased a sample of oil for examination. The oil was similar in appearance to some I expressed myself from some freshly dried almonds obtained from Neyoor. The following notes give the results of a chemical examination of the oil made with the assistance of Allen's 'Commercial Organic Analysis.'

The oil had a greenish-yellow colour, thick consistency, fragrant odour and bitter taste. It commenced to congeal at the temperature of 19° C., and became quite solid at 16°, when it had a specific gravity of 0.9315.

The free acidity of the oil was found by shaking a weighed portion with alcohol and titrating the solution with normal alkali, using phenol-phthalein as an indicator. One hundred grams of the oil required 1.89 grams of caustic potash to neutralize the free acids.

The oil was saponified by boiling a weighed quantity for one hour with alcoholic potash, and the excess of alkali was determined by titration with normal hydrochloric acid. It was found that 100 grams required 19.6 grams of KHO to convert it into a soap; the saponification equivalent was therefore 285.6. The soap solution in alcohol, allowed to stand for a few hours partially crystallized into lustrous white scales.

The volatile fatty acids obtained by Reichert's distillation process were very small in quantity, 2.412 grams of oil required the equivalent of 0.1 c. c. of normal alkali for saturating the volatile acids, which is equal to 0.23 per cent. of KHO.

Two drops of sulphuric acid added to 20 drops of the oil gave a red coloration with orange streaks; after stirring the whole became an orange-brown mixture. The oil shaken up with an equal volume of nitric acid, sp. gr. 1.4, formed a light reddish-brown emulsion; after standing for an hour the oil separated with a rich mahogany brown colour, and the lower acid liquor was red. Treating the oil according to Poutet's elaidin Reaction, and working at a temperature of 20°, the mixture of oil and nitric oxide solution congealed in two and a half hours; after twenty four hours it remained as a firm butter-like solid of a dull lemon colour, and yielding to the pressure of the finger.

5.045 grams of the oil were on November 7 exposed to the air in a watch-glass under a bell-jar, and weighed daily for one month. The increase in weight was just appreciable after the exposure; the weight on December 7 was 5.047. This quantity of oil heated in a water-oven at 93° for eight hours gained 0.006 gram only.

The insoluble fatty acids amounted to 90.85 per cent. They crystallized into radiating tufts of acicular crystals, having a melting point of 37.6°, and a specific gravity of 0.9237 (solid) at 16°, and of 0.8688 at 90°. Their mean combining weight, obtained by titrating the washed and dried acids with normal alkali and using phenol-phthalein as an indicator, was found to be 283.1. A lead soap of the fatty acids was made by decomposing the potash soap with a hot solution of lumbic acetate. After washing and drying, 1 gram was weighed out and shaken up with ether; the oleate of lead, or soluble lead soap, weighed. 44 gram after the ether had been rapidly driven off. The lead soap insoluble in ether was decomposed, and the purified fatty acids had a melting point of 58°.

The oil agitated with 85 per cent. alcohol removed the green colouring matter and a sticky extract possessing the peculiar melilot-like odour and the bitter taste. This extract amounted to about 7 per cent.; it was almost entirely soluble in dilute alkalies with an orange colour, precipitated unaltered on the addition of acid, and was perfectly soluble in ether and chloroform. The green mass was boiled with water and the filtered liquor evaporated had the odour of coumarin, but no rhombic crystals of coumarin could be observed in the slight residue when examined under a microscope. The alcoholic residue was crystalline, and contained some free fatty acids of the oil.

The conclusion arrived at from the examination of the laurel-nut oil is that it cannot be regarded as a drying oil, nor altogether as non-drying, but must take up an intermediate position between the two. In endeavouring to classify this oil with those that have already been investigated, the task is not difficult. Most of the experiments exhibit in a very striking manner a strong relationship to those of the cotton-seed oil group. The saponification equivalent, the high melting point of the fatty acids and the free acids are very remarkable, and the sulphuric and nitric acid tests are particularly allied to those performed upon cotton-seed oil.—*Pharmaceutical Journal*.

JAPAN RICE.—A prominent dealer says:—"The half has not been told respecting the merits of the Japan rice. It is the equal of the Carolina head in grain and color; in food properties it outranks all other styles; in price it is far below any similar and competing grade of domestic or foreign. These facts probably account for its phenomenal sales and popularity."—*American Grocer*

CINCHONA PROSPECTS: A VISITOR
FROM JAVA.

Ceylon has a visitor at present from Java in the person of Mr. J. Wijinschun-dom who is interested to a considerable extent in cinchona, as well as indigo, sugar, and coffee. Our visitor is a member of the Soekaboemi Association and trusts that one or two representative Ceylon cinchona planters may visit Java this year to devise means for putting the Cinchona Syndicate in working order. The export of bark from Java next year he puts at 3,000,000 half-kilogrammes, about 3,300,000 lb., averaging fully 4 per cent or equal to about 6,600,000 lb. of the average quality of Ceylon bark. Mr. Dom is surprised to find that so little is done with grafting in Ceylon: in his fields he gets one man to do 200 to 300 grafts a day of Ledger or high class hybrid—all selected by careful analysis—on ordinary hybrid or succirubra stocks and with scarcely any failures. Mr. Wijinschun-dom speaks of coffee in East Java as looking very flourishing at present and a good deal is being done with tea, tobacco and indigo; but sugar is under a heavy cloud with disease in the canes and other drawbacks. He mentions a curious circumstance in his experience as an indigo planter of the much less quantity extract he is able to get from his leaves, than is got in India. The return of crop per acre in leaf is much heavier than in India, but in extract it is less. Our visitor is going on to India to learn somewhat of the different processes followed in Indigo Factories there. Meantime this exceptionally intelligent Java proprietor—speaking English well—is determined to see all he can of "Cinchona" in Ceylon. We tried to dissuade him from travelling in the present weather so far as Uva and after all perhaps to see but poor fields, so much having been cut down. Oh! but that will be a great satisfaction to me and my Java friends, to be able to say that so much has been cut, that little is left—was the substance of his reply. So, Mr. Wijinschun-dom has started for Nuwara Eliya intending thence to visit Udupussellawa, Badulla district, Madulima, and in coming back, the Agras division of Dimbula. The less evidence he finds of Ceylon being able to keep up her recent exports of bark, the better pleased he will be. We bespeak all due attention to our visitor. He ought to be shown somewhat of the ravages done by an attack of caterpillars on some cinchona fields in Uva. We have heard of one case where a clearing of considerable extent, after the trees had been shaved once or twice, was nearly killed out by an attack of caterpillars eating the leaves and so affecting the sap that the tree died and the bark which could scarcely be separated, was useless. In connection with cinchona in Java, Mr. G. D. T. Bell, in a letter received today, wishes to correct one or two inadvertent slips in our account of his visit. One was that there was a large extent under cinchona in Java. Mr. Bell writes:—

"I had in fact no opportunity of learning what amount of cinchona there is growing in Java, and I only wished to say that from what I saw and heard, the cinchona was strong and healthy and generally gave a very much higher percentage of quinine than that in Ceylon. You also mentioned that I saw Mr. Mundt. I did not see that gentleman but Mr. Van Komunde, the Director of the Government Cinchona Gardens, to whom you were kind enough to give me a letter of introduction and who gave me no information as to the quantity of cinchona in the Island."

TOBACCO IN NORTH BORNEO.—The following is from a reliable quarter as to the progress making with tobacco in North Borneo:—

A report was current in Hongkong that the Darvel Bay and Marudu Bay tobacco of last year's crop had been most favourably priced in Europe. We expect to hear the report confirmed via Singapore. The reports of this year's crops are favourable all round, more especially on the Segaliud river in Sandakan Bay. Another tobacco company has been formed in Hongkong to plant on the Kiribatangan river. A good deal of building is going on in Sandakan, and a small but steady influx of the artisan class of Chinese from Hongkong, irrespective of estate labourers. Both Malay and Chinese coolies are in great demand for the estates.

THE STRAWSONIZER.—A Colombo correspondent writes:—"I see your London correspondent takes up the 'Strawsonizer.' Our London folks called at the Company's office, but they were not able to get much information. However, they write as follows:—'At present none are being made, and it is very difficult to see how it could be of any use amongst tea or coffee on an average Ceylon estate.' I send you the supplement to *Bell's Weekly Messenger* on the machine, but my friends have formed a poor opinion of it and write plainly on the subject. They were told in the London office that 'arrangements were being made' for its manufacture."—*Bell's Weekly Messenger*, however, bears splendid testimony to the value of the machine, from "all sorts and conditions" of press and agricultural authorities. There must be a great deal in the Strawsonizer when it is the subject of repeated praise in the *London Times*, *Agricultural Gazette*, *Farmer's Gazette*, *Mark Lane Express*, and from Professor Munro, D.Sc., F.C.S., Mr. Charles Mitchen, Agricultural Adviser to the Committee of Council for Agriculture, and Dr. Frear, Messrs. Sutton. We are not convinced that a machine used for hops, vines &c. cannot be advantageously adapted for coffee. It might be made of a size to be drawn by coolies along coffee estate paths if not among the bushes. Our correspondent should ask his London friends to apply again and to make enquiry at one or other of the public men who testify to the admirable work done by the "Strawsonizer."

PROFESSOR DRUMMOND ON THE AFRICAN ELEPHANT AND IVORY.—In a review in the *British Trade Journal* of Professor's Drummond's "Tropical Africa" we find it stated:—

On the question of ivory Professor Drummond remarks that the African elephant has never been successfully tamed, so that his strength is a failure. "As a source of ivory, on the other hand, he has been but too great a success. The cost of ivory at present is about half-a-sovereign per pound. An average tusk weighs from twenty to thirty pounds. Each animal has two, and in Africa both male and female carry tusks. The average elephant is therefore worth in pounds sterling the weight in pounds avoirdupois of one of his tusks. I have frequently seen single tusks turning the scale upon ninety pounds, the pair in this case being worth nearly 100*l.* sterling—so that a herd of elephants is about as valuable as a gold mine. The temptation to sacrifice the animal for his tusks is therefore great; and as he becomes scarcer, he will be pursued by the hunter with ever-increasing eagerness. But the truth is, sad though the confession be, the sooner the last elephant falls before the hunter's bullet, the better for Africa. Ivory introduces into the country at present an abnormal state of things. Upon this one article is set so enormous a premium that none other among African products secures the slightest general attention; nor will almost anyone in the interior condescend to touch the normal wealth, or develop the legitimate industries of the country, so long as a tusk remains." The author believes that when the elephant is exterminated one stage in the abolition of the slave trade will be reached, this being due to the fact that for every tusk the Arab trader purchases he must buy, borrow, or steal a slave to carry it to the coast

IMPROVED PADDY CULTIVATION.

We call attention to the report furnished on page 288 by the Assistant Agent of Matara, as to a considerable extent corroborative of what Mr. Elliott wrote on the subject of Paddy cultivation from the experiments instituted by him. Of course, Matara (with Batticaloa and Madampe districts) has always been regarded as about the richest rice-growing division of the island; but Mr. Baumgartner's experiment shows how great is the scope for improvement even among the farmers under the premier Assistant Agency. Here are three typical cases brought before us in which the usual return of crop has been increased 50, 60, and 100 per cent without the aid of manure or special means of any kind, save the due attention to careful work which first-class farming ought always to ensure. In the first case, the competitor in place of 6 fold, his usual average, got 20-fold, or a crop of 40 bushels per acre. In the second instance, the two bushels sown became 46½ bushels in crop or 23-fold instead of the average of 15; and in the third case the return in place of being 10., was 15-fold. We congratulate the Assistant Agent on the beginning he has made in competitive trials which cannot fail to become increasingly popular, year by year. As in the case of the Matara Agricultural Show, though Mr. Baumgartner may find working independently of the headmen discouraging at first, yet it is certain to issue in results of a very satisfactory and lasting character. A certain degree of improvement may be expected to follow each succeeding attempt; and we trust to see the Paddy-growing Competition established as an annual institution not only in Matara, but in all other rice-growing districts, as another, and not the least potent, means of stirring the people to pay more attention to their farms and the best mode of rice cultivation.

AN ENGLISH RUBY COMPANY FOR
BURMA:—WHY NOT A LONDON GEM
COMPANY FOR CEYLON?
NO. VII.—THE UPPER BURMA RUBY
REGULATIONS, 1887.

Shortly after the deposition of King Theebaw from the throne of Mandalay, followed by the annexation of Upper Burma by England, the Government began to take into consideration the rules and conditions under which the local trade in the world-famed rubies of Burma should be regulated. Their deliberations resulted in the promulgation of the Upper Burma Ruby Regulation, 1887, with the rules published by the Chief Commissioner of Burma, a measure which, though brief and concise in its form, requires as much study and attention to enable the reader to grasp its provisions as any of the old legal forms of a hundred years ago. Its provisions are moreover of a very stringent character, and in some points of so arbitrary a nature, that the local authorities at Mandalay were forced to admit a few months ago that they did not believe they could be enforced in their entirety. The first effect of the publication of this Ruby Regulation was almost a paralysis of the trade in gems, at any rate in Upper Burma, and to a great extent also in Rangoon. It added also emphasis to the generally prevalent friction between the rulers and the ruled, which unfortunately seems year by year to be intensifying rather than diminishing throughout the newly-annexed territory. The Ruby Regula-

tions however are chiefly of interest to us as bearing upon Streeter's concession in Burma. Of this concession no mention whatever is made in the publication itself, or any provision made for any Company or Companies apart from licenses granted to individuals; and unless some special act has been since passed in favor of Mr. Streeter's Company, it will be seen that the last shadow to a claim for monopoly in ruby mining, put forward on behalf of that Company, entirely vanishes from the scene. It will be remembered that the London Correspondent of the *Observer* justified Mr. Streeter's assertion of monopoly on the ground that the Company alone were entitled to the exclusive right of using explosives, and machinery without which nothing could be done of any importance in gemming operations. Bearing this in mind we turn to the Ruby Regulation, and the first thing that bears upon the subject is the announcement that the regulation extends to the whole of Upper Burma, except the Shan States, but "nothing therein shall be construed to take away or derogate from any right established to the satisfaction of the local Government." The latter part of this is delightfully vague; "any right established to the satisfaction of the local Government" opens a very wide field indeed in opposition to monopoly. Again it is on these very Shan hills, which are expressly exempted from the scope of this regulation, that the thousands of square miles of ruby-bearing country are situated and on which there is practically an unlimited field for gemming operations. Turning to preliminary definitions, we find "precious stone" means ruby, sapphire, or spinel, and includes any other stone which the local Government may declare to be a precious stone. "Stone" tract means a tract which the local Government has declared to be a local area in which precious stones are found. "Native," used with reference to stone tract, means a person who was born, and during the five years immediately preceding the commencement of this regulation has habitually resided in the stone tract. The phraseology of these regulations is in many instances peculiar, with an utter absence of ordinary legal terms.

Section 3 provides that "except as permitted by rules under this regulation, no one shall—if he is not a native of a stone tract, reside therein; dig for or raise any precious stone in a stone tract; cut or dress any precious stone, possess any precious stone in a stone tract or, for the purposes of trade, in any place beyond the limits of a stone tract; buy or sell, or be otherwise a party to the transfer of any precious stone, or transport any precious stone.

Section 4, however, provides that the local Government may make rules consistent with this regulation to permit on such payments, if any, as it thinks fit and to regulate all or any of the above-mentioned prohibitions as well as (sec. 5) granting licenses "to do anything permitted by the rules to be done." Let us now turn to the "rules under the Upper Burma Ruby Regulation," a notification from the Revenue Department, and follow up this part of the subject first. Sec. 3. A person who is not a native of a stone tract may reside therein with the written permission of the Deputy Commissioner, subject to such condition as the Chief Commissioner may prescribe.

Section 4. Stones may be dug for or raised in pursuance of a license either (sec. 5) ordinary or extraordinary. An ordinary license shall be a license to dig for or raise precious stones by the native methods, and shall not authorize the use of any explosive substance or machinery and (sec. 6) may be granted to any native of a stone tract or with the previous sanction of the Commissioner,

to any person who resides in the tract with written permission, and may not exceed one year in duration.

An extraordinary license shall be a license to dig for or raise precious stones by any method, and may with the previous sanction of the Chief Commissioner be granted by the Deputy Commissioner to any person, (sec. 9) for such period, in such form, on such conditions and in consideration of such payments as the Chief Commissioner in each case directs.

Following the above there are a number of regulations regarding the *modus operandi* of ordinary licenses for gemming, which would be of interest should the Government of Ceylon think it advisable to regulate the native gemming operations, now left to themselves and worked at the option of the owners or leasees. There is nothing more said about extraordinary licenses, which we accordingly find in this position. Permission may be granted by the Chief Commissioner, to any person, for any period, and under any condition he chooses, to carry on gemming operations by use of machinery and explosives, or by any other method they may think fit. This effectually disposes of the straw at which the drowning monopoly attempted to grasp—it has not left to it even this one remaining claim; the exclusive right by the Company to employ explosives and machinery, has no more existence in reality than any other of the many fictitious advantages claimed on its behalf by the promoters.

Returning now to the Ruby Regulation (sec. 5, 2) "A license to dig for or raise precious stones in a stone tract may impose on the holder thereof the condition that he shall, at the option of the authority granting the license, sell at his own valuation to that authority all or any stones which he or any person permitted by the license to work under him finds or raises, or pay on that valuation to that authority such duty in respect of the stones as the local Government directs." The local Government is empowered to "grant by lease, or other appropriate instrument, with respect to all or any stone-tracts or to any stone-tract, the right to exercise this option; and (sec. 16) if in the opinion of the local Government, the acquisition of any land on behalf of such grantee is desirable for the purposes of this regulation, the local Government may at the request of the grantee, proceed to acquire the land under the provisions of the Upper Burma Land Acquisition Regulation of IX of 1886, and on payment by the grantee of the compensation awarded under that Regulation, and of the charges incurred by the Government in connection with the proceedings, the land shall vest in him subject to such conditions, if any, as the local Government may prescribe."

This portion of the enactment would seem to be specially framed for the benefit of prospectors. Anyone disposed to speculate in gemming may travel about and see what is going on. When he finds diggers—with licenses—doing well on some particular spot, he applies to the local authorities for a grant of that land, and under certain regulations in due time acquires it, with a right to the gems found by the license holders, whose claims terminate within a twelvemonth of date of their licenses, leaving him free to do as he likes.

Authority is also given to summarily search for stones liable to confiscation whenever the authorities have reason to believe from personal knowledge or information given by any person, including entrance to building, vessel, or place, breaking open doors and removing obstacles to entry; detention, search and arrest of the suspected person and any person in his company.

A police officer, railway servant, carrier of goods or anyone in his employ, who is aware of the commission of any offence, or the intention to commit an offence, shall be legally bound to give immediate information, orally or in writing, to a Police Magistrate or to a police officer above the rank of a constable.

By way no doubt of showing that the Government intend enforcing these regulations and making all the profit they can from the natural resources of the newly acquired territory, it is enacted, that imprisonment for a term of one month for the first offence, and for 6 months for any subsequent offence, as well as fine, will follow the person who "in contravention of this regulation resides within a stone tract, or digs for, or raises any precious stone, or possesses any precious stone in a stone tract, or for the purposes of trade, in any place beyond the limits of a stone tract, or buys or sells, or is otherwise a party to the transfer of a precious stone, or transport any precious stone, or fails or refuses to comply with any provision of any rule under this regulation."

It shall be presumed in a prosecution, until the contrary is proved, that any stone for which the accused person is unable to account satisfactorily, is a stone in respect of which he has committed an offence, and (sec. 8) liable to confiscation. Whether the person charged is convicted or acquitted—the stone may be confiscated on the decision of the magistrate.

If a stone is seized—and the offender is not known or can't be found, the stone may be confiscated after a month's notice to give opportunity for its being claimed, and "when a stone not in the possession of any person cannot be satisfactorily accounted for, it is, under similar conditions, confiscated." The magistrate, Deputy Commissioner or other officer may, instead of ordering the confiscation of a stone, give the owner an option to pay, in lieu of confiscation, such sum as the officer thinks fit."

It would seem from these, and many others of the rules and regulations, that, the officials of Upper Burma should serve an apprenticeship to a jewel-dealer's business to enable them to appraise the value of the precious stones with which they will have to deal. The want of such technical knowledge must without doubt be often injurious to the due and just administration of the act under reference, and it is no matter for astonishment that in the absence of such technical knowledge its promulgation has not been received with much favour by the inhabitants of the country placed under its provisions, a country, it must be remembered which we have only recently annexed, where our authority is by no means yet firmly established, and where all the actions of Government are looked upon with dread or suspicion. The mistakes already made by those in authority have been both grave and numerous, and it will not be surprising if the terms of the Ruby Regulations in any case—cumbersome and expensive to work—were very considerably modified within a short period, and in all probability, all restriction will eventually be removed as they have been in this island.

OEYLON TEA IN THE NORTH OF SCOTLAND.

A well-known planter writes to us :—
"I send you the circulars of Brehner & Grant, the largest wholesale tea dealers in Aberdeen. The one in 1886 represents my views written when I came last from Europe, and you will see their firm then

recognised the excellency of Ceylon tea. In their circular of 1888 they express greater confidence than ever; and in a private letter from Mr. Grant, he says they had put 2,000 half-chests of Ceylon tea last year among their customers. I do think now that Ceylon tea is now fixed on a firm basis. All we want now is *quantity and quality combined.*"

From the circulars we quote as follows:—

(Established 1828.) 48 St. Nicholas Street,
Aberdeen, April 2nd, 1886.

CEYLON TEA.—The rapid development of Tea growing in Ceylon, the high reputation it has acquired, and the growing taste for it among consumers, has induced us to give special attention to Ceylon Tea. Until 1884, separate statistics were not kept, but we give below the figure—since Tea was grown in Ceylon as an article of export—sent us by a well-informed correspondent resident there. We also give the acres planted.

* * * *

Anyone studying these figures will see at once the great importance of Ceylon Tea as an article of commerce. We commend them to the attention of our friends. From the fact that several local men are resident in Ceylon, with whom we are personally acquainted, we have exceptional opportunities of acquiring information, and of securing the produce of the best gardens. Some of our correspondents are now shipping regularly. We may add our opinion as to the merits of Ceylon Teas. Some of them combine the best points of both China and Indian Tea, and are therefore admirable self Teas: others, from their great body and fine flavor, make a valuable addition to any blend. We will be pleased to submit samples on hearing from you.

BREBNER & GRANT.

48 St. Nicholas Street, Aberdeen, August 1888.

"I called for a cup of Tea."—*Pepys*, 1661.

TEA.—The consumption of Tea in this country since its introduction by Dutch merchants from 1645 to 1660, when it was first known in the London Coffee Houses, has grown to enormous proportions.

INDIA.—Until 1860, China practically held the field, for, although Tea had been grown in Java, &c., was discovered in Assam, and the first experiment in Tea growing was made by the Indian Government in 1835, Indian Tea was hardly known as an article of commerce before 1860. Last season India exported 86,000,000 lb.

CEYLON.—Ceylon Tea was first offered on the London market in 1880. On the whole, it got a favourable reception from the Trade; but many of the Teas, fresh when brought, soon become flat and lost flavour rapidly. This created a prejudice against Ceylon Tea, which probably even yet has not entirely disappeared. In our opinion, these results were largely attributable to want of knowledge on the part of the Planters. With an article of such delicacy as Tea—requiring knowledge of plucking, withering, fermenting, firing and packing—it would have been Utopian to have expected Tea perfectly matured and manufactured at first. Ceylon Tea must still be selected with knowledge; but, with careful selection, Ceylon produces some of the finest Teas we have ever handled, combining the strength of the finest Indian with some of the delicacy of the best China Tea.

Two years ago we issued a circular giving statistics of Ceylon Tea, based on carefully-sifted information. Our estimates of the crops have been verified, and it is probable our estimate of 30,000,000 lb. for next season will fall short of the actual production.

CHINA.—The Finest China! Must it be said these are not what they once were. Two years ago we had some fine Tea from China, with great quality and delicacy in the cup, but lacking the body and fragrance of some of the old clipper-shipped Teas—Teas by the "Lammermuir," the "Cairngorm," and other famous clippers, which some of our older friends will still remember.

BREBNER & GRANT.

Our correspondent adds:—"I think Messrs. Brebner & Grant are Ceylon benefactors." Certainly and their names will appear. Aberdeen should be well supplied now: we notice that "Old Colonist"'s latest address is "Tea Planters' Depot, Old Quay,

Aberdeen." The following advertisement appears in the *Northern Advertiser*:—

IMPORTANT.

Whereas it has been brought to the notice of the Tea Planters' Association that certain unscrupulous vendors are in the habit of mixing our teas with a large proportion of spurious leaf: We hereby intimate that we have found it necessary for the better protection of our interests to open Direct Agencies, where Genuine Ceylon and Indian teas can be guaranteed, and sold to the public in any quantity, from ounces to tons, at 1s 8d per lb. upwards.

ABERDEEN AGENCY—
THE PLANTERS' DEPOT.
A. R. Gray's Buildings, Upper Quay.

THE "MAZAWATTEE" BRAND OF CEYLON TEA.

ONE OF THE LARGEST BUYERS OF CEYLON TEA—A VISIT TO MR. DENSHAM—HIS RESIDENCE—"MAZAWATTEE" NOT PLAGIARIZED FROM "MARIAWATTE"—SOME ACCOUNT OF MR. DENSHAM'S BUSINESS IN CEYLON TEA—BLENDING AND PRICES—CEYLON VERSUS CHINA—THE MOST "LUSCIOUS" TEA IN THE WORLD—THE PACKET TEA TRADE—A VISIT TO THE BONDED WAREHOUSES—WORKING OF THE TEA MACHINERY—HOW TEA PACKETS ARE MADE—MR. DENSHAM ON CEYLON OOLONGS—SOME SAMPLES OF INDIAN TEAS—THE MARKET FOR CEYLON TEA.

LONDON, Aug. 21st, 1889.

Several London tea brokers in the Mincing Lane salesrooms pointed out to me Mr. Densham, the "Mazawattee Brand" tea dealer, saying he was one of the largest buyers of Ceylon tea, doing much good to our island by his extensive transactions in the article and his wide advertising of it. I was introduced to him, and went by invitation to see his place, which is excellently situated in commodious buildings on the opposite side of the street to the Mark Lane station, with a wide square between it and the Tower of London, a good view of which is obtained from the upper windows.

Mr. Densham told me he has been visited by several Ceylon men. He says the idea of plagiarizing anything from "Mariawatte" never entered his head when selecting "Mazawattee" as his brand. He went on for a time in three rooms, without a brand, but as his business grew he was advised that a brand was desirable and also found that the whole building of six large floors was necessary for his rapidly expanding requirements. He has lately engaged the adjoining warehouse of eight similar floors in addition, and this: he expects soon to have fully occupied, so rapidly is he progressing.

At present his daily output is about 100 chests, the great bulk of which is Ceylon tea, of which I saw several leading marks. All his high-priced teas, viz., @ 2/6 and 3/ a lb., are entirely and purely Ceylon tea; the lower priced qualities @ 2/ and 2/2 a lb. are blended with Indian and other growths which supply the briskness and pungency lacking in the lower qualities of Ceylon, but I was assured the bulk of the tea used is Ceylon. He points out that it is necessary to have blends such as he has adopted and affixed prices at which he may stand to lose sometimes, though not often,—much more frequently, of course, the result being the other way,—as by this means alone can a uniformity in quality be assured, uniformity being a great desideratum with his constituents.

I annex two sentences from a short article on tea in a small book entitled "The Ladies' Handbook of the Language of Flowers and Precious Stones" he issues with his packages:—"China has long since ceased to send us her finest teas, and we now to a great extent depend upon India

and Ceylon for our quality. The development of the cultivation of tea in Ceylon, during the last five or six years, has been enormous, and we now obtain from that island a certain proportion of tea that rivals the fine old China teas. It has rested with the Mazawattee Ceylon Tea Company to take advantage of this new production of fine tea from Ceylon, and to supply a want long felt. By skilful selection and blending of the finest Ceylon growths, they have given fresh life to the taste for fine tea, which had become so nearly extinct in this country. They have more than 3,000 agents throughout the United Kingdom, and there is now no excuse for people to drink rubbish themselves or to give their friends such a wretched apology for tea as should bring a blush to the face of every right-minded nation."

Here is a copy of the label:—

Mazawattee:

A high class tea

from the sweet-scented island

Ceylon

which produces

the most luscious tea in the world.

"Maza," I am told, is short for "Mazadhar," an Indian word in unison with "luscious" which was on the label before the adoption of the brand.

The business is essentially a packet one, the blend, price, and frequently the grocer's name being on the label, a large stock of labels being on hand for the packages of constituents. "Loose teas," that is blends in chest and half-chest quantities, for those who retail in small quantities are also available. Nothing is omitted that is necessary to be done, to meet the requirements and gain the support of "the million," whom of course it is the interest and bounden duty of growers and caterers alike to endeavour to reach and satisfy.

Mr. Densham claims to be the originator of the packet business, and many of those who predicted failure, ridiculing the idea, are now active competitors: so much so, that there are large packet-making and blending business, carried on in some of the bonded warehouses. I have personally witnessed some very interesting and busy scenes there, and saw even China tea being put into pretty canisters and packets for export.

By the way, on my visit to some of the bonded warehouses to see the reweighing and repacking and rebulking processes of tea as done there I passed through the Jews' market in Whitechapel and under the gas lamp in Castle Alley of infamous and notorious fame as being the scene of "Jack the Ripper's" latest disgusting tragedy. The Jews' market is a rowdy place, well stocked though it be with excellent provisions and requirements of all sorts for the outer and inner man; and numerous policemen and detectives in and out of uniform are moving about to preserve order.

It is interesting to see the gradations in Mr. Densham's premises from small hand-power mixing, sifting and cutting machines to the large ones now in use driven by a gas engine and capable of each holding eighteen chests at a fill, finishing the work in about 45 revolutions of the machine. Many means for economizing labour are used, such as lifts and shoots, and spaces are marked with the name of each firm of carriers, where each evening the driver can see what loads are ready for him to carry away. The lead is cut by the manufacturer in sizes to suit $\frac{1}{2}$, $\frac{1}{4}$ and 1 lb. packets, so there is little waste.

What interested me as much as anything was the rapidity with which the packets were made up. Three boys at one table make three thousand two hundred, one-quarter lb. packets in a day; the work being divided as follows:—

One boy preparing packet;

" " weighing and filling;

" " pressing with lever and closing.

The labels are put on by separate hands; and the packets being of uniform size put on trays of known capacity are easily counted and quickly packed in boxes for removal and dispersion by van and rail all over the country.

CEYLON TEA.

P. S.—I have omitted to mention that Mr. Densham expressed himself pleased with some of the "oolongs" which have come from Ceylon lately, and said he wished there was more of this kind available. A prize for "oolongs" might be offered at your local Shows. I was shown samples in a broker's office of Neilgherry "Flowery Pekoe" purchased at 15s. a lb. and "Orange Pekoe" purchased at 10s. a lb., 15 lb. of each variety, for the Indian Court at the Paris Exhibition. There is a brisk market in London for your finest teas; competition for them being very keen.

CEYLON TEA.

BARLEY GROWING IN THE NAWALAPITIYA DISTRICT.

Our Kandy correspondent writes:—"The Ratemahatmaya of Uda Bulatgama (Nawalapitiya district) has by way of experiment tried to plant barley from seeds received from the Brewery Company, at Nuwara Eliya. The garden where the barley has been tried is in Weligoda, on the Dolosbage road, about one and half mile from Nawalapitiya. The result has been a great success. The ears of corn are well formed, eight inches in length, and the R. M. expects a good crop almost immediately. The extent down is about $\frac{1}{2}$ of an acre. The R. M. has been distributing seed to others in the neighbourhood and is willing to advise those who will undertake to plant the grain. Unfortunately, the recent rains have damaged the corn a little—but the stalks are still 4 feet high and present a very good appearance. The stems, he says, are like hill paddy. The R. M. thinks the best season to plant is in February. The plant require very little moisture. Three months time is all that is required for the plant to grow fully. The R. M. will gladly give information to persons desiring it. Some specimen of the ears of corn are left at the Nawalapitiya resthouse for inspection of Visitors. Mr. Giriagama the Ratemahatmaya is a very intelligent headman and deserves great credit. The natives of his district and of other districts would do well to follow his example in this respect."

NEW USE FOR TIN CANS.—Scraps of tinned iron have long been a waste product, whose application, for any purpose worthy of the intrinsic value of the metals contained in them, has been an unsolved problem. It is true that scraps of this kind have been cast, but the hardness and granular structure render the metal fit only for use as weights. Also, to a slight extent, the tin has been removed by electrolytic processes. "But," the American Manufacturer says, "there has not been any definite use of this product as a material manufacture until its recent use for nails. Scraps of tin are cut by dies into rectangular bits, with a length of about three times their width. These scraps are then fed from an automatic hopper between dies, when they are squeezed first to square form, like a nail, and then headed. Nails of this kind are well fitted for many purposes, being free from tendency to rust, also light, very rigid, and capable of being driven into the hardest wood without buckling."

ERNEST TYE, 14, St. Mary Axe, E. C.

FROM THE CINNAMON DISTRICT.

Kadirava, Sept. 13th.

After the week of rain from the 4th to the 10th, it looked as though we were to have a little fine weather. The 11th was bright and warm and so was the 12th all day, but at night the rain fell in torrents, and this morning my gauge measured 4.50 inches. Clouds are succumbing away towards the Peak, and occasional rumblings of thunder presage I fear another downpour tonight. The winds and clouds are from the south-west.

14th, 6 a. m.—Rainfall last night 4.83; total for 13 days 18.78 inches! "Oh dear, what can the matter be!" With wind and rain from the S.-W. this cannot be the north-east monsoon. What is the weather report from Madras? If the N.-E. is on it must have burst there before it reached us. Poor "goyiya," I pity you! The "maha" crop just ready to be reaped will be considerably damaged, and much of the "yala" recently down will be either washed out or rotted. Much privation must result, and probably sickness too. Government Agents should be watchful and note the first signs of distress amongst their people; and the medical authorities also be ready so that should it unfortunately become necessary, timely relief may be afforded. A very wet September does not necessarily mean a dry October, November and December: in fact it serves to point the other way; see rainfall returns on page 432c of your Directory for 1887-88, notably for the year 1877.

A VISIT TO THE GEM MINES IN SABARAGAMUWA.

[FROM OUR MINING CORRESPONDENT.]

On reaching the mines the first thing that strikes the eye is the large mass of what appears to be clay of a light brown colour, heaped in an inclosure boarded round and containing many tons, which to the casual observer seems nothing more than ordinary earth or puddled mud, but when washed from the mud it presents a very different appearance, being composed of

GEM GRAVEL.

At the time of my visit everything about the mouth of the shaft was smothered in clay, even the workmen were overhead and ears in it. The gravel was being transported from every side, underneath the ground, to the bottom of the shaft, and on its reaching the top it was spouted down to the washers, to where we made our way down a breakneck path till a platform was reached, erected for the purpose of receiving the gravel as it came down the spouts. Under this platform was a cradle into which it was thrown by the men in attendance. The cradle is about 20 ft. long by 3 wide laid in a sloping direction with a spout of water entering at the top, and at the bottom there is an iron grating through which the water is allowed to escape. Several men are posted along the front with mamoties to work the gravel backwards and forwards till pretty free from mud, then lift it up as required by the

basket men, who stand in a line in a dammed up piece of the stream and finish off the washing in the usual way.

WATCHING THE MEN

in the trough was the brother of the mine owner and another relation, and on the opposite side where the baskets were to be searched were seated the representative of the land owner and another relation of the pit-owner in a small hut with a bamboo about 2 in. in diameter, and one foot long stuck in the ground in front of them for receiving the gems. I was asked to take a seat beside them, and gladly accepted a bowl of strong tea to warm me up, for it was blowing and raining as it only can do on the Morawak Korale side of the Gap.

THE SEARCHING OF THE BASKETS

when brought up by the washers to the feet of those two men was really amusing, and was certainly the most interesting part of the proceedings. The baskets with about $\frac{2}{3}$ full of washed gravel, out of which all large stones and rubbish had been thrown during the washing, after careful examination, were brought into the hut, laid down, tilted up, and a search began by turning up the coat sleeve at the same time folding up the forefinger and thumb of the right hand and plunging the remaining three fingers into the gravel near the edge: it was thus turned over little by little till every particle was thoroughly examined and every gem of any value picked out and dropped into the bamboo in front of the two examiners who appeared to be most eager and anxious in their search as well as the bystanders. When all was finished there was a rush for the baskets, which were emptied out down the stream, and all the residue in the shape of dallam, small gems, &c., were carefully gathered for sale by the lb. to the dallam tambies. I watched this interesting work for half-an-hour, then asked to be shown what was in the bamboo, which was reluctantly handed to me for examination. I found on emptying out the contents that I had a handful of gems mostly sapphires, for the purity of which those pits are famous. Amongst them was a beauty, a little larger than a pea, of peacock blue without a flaw: this was the most perfect of the lot, the others being irregular in shape and defective in color. The rain now became so incessant and heavy that the men complained of hunger, and looked like so many drowned rats. A retirement to the midday meal was consequently suggested, and we made our way to the lines, at the end of which was an office, where I was invited to walk in, hoping to obtain some more substantial information than I had already gathered, from the books of the establishment. I raised no objection and walked in: when seated at the writer's table I had my eye on the

GEM BAMBOO,

which was very carefully emptied of its contents on to a piece of foolscap paper, counted, valued, and sealed with the mine owner's monogram; but before doing so, (by the bye I was surprised to see) several very small gems selected and put into a small white bottle which already contained a good collection. I asked what this performance was for (having observed some manœuvring being gone through), and was informed that they were an offering to Buddha: without this no success would attend their labours. Out of each packet the samy must get his lot, which is taken and presented to the temple figure of Buddha. After sealing, a ledger was produced and an entry made: "No. 9. 50 precious stones, value R500," which I think was a low valuation for the lot, for I am sure the good gem which was found during the time I was present was worth at least R250,

about R100 per carat. The other eight parcels were all valued at a little over R500 each, and had all been sent down to Rakwana to be sold by auction. I learnt afterwards they had realized R1,250, from the pit owner's books in Rakwana, who was not present during my visit to the mines.

THE CAUSES OF ABANDONMENT.

It must be remembered that I am only mentioning the gravel of one pit: the other had not been touched, and only about one-quarter of the one in question had been washed, and had realized the handsome sum of R1,250 towards defraying an expenditure of R2,500. The washing was expected to continue for six weeks longer, and should a large gem be found its value alone would cover the whole expenditure of both pits, which is reckoned not to exceed R5,000. There is therefore little doubt that the steady daily return from the gravel washed shows clearly that the gemming enterprise, even in the primitive native way, pays when followed perseveringly. When the heavy N.-E. monsoon rains begin those pits will be abandoned on account of the water; if nothing else. You may say—what else would cause abandonment. Well there are many things unforeseen which turn up: sometimes rock, large boulders, a spring of water too large to contend against, and last, but not least, the failure of the stratum of gravel, which sometimes becomes smaller and smaller, from six feet to one or two inches, when the great distance from the shaft and other reasons compels abandonment. After ten, fifteen, and twenty fathoms have been tunnelled in every direction, all these obstacles could doubtless be overcome with the modern scientific mining appliances and especially by the use of the diamond drill which would enable the miner to find deeper gravel and strike in other places when lost.

ALL GEMMING OPERATIONS ARE SUSPENDED

during the heavy rains which prevail for the first few months of each monsoon, as it is found impossible to keep the water down, at any great depth. At the time of my visit there were six mines being worked, averaging from seventy to one hundred feet deep, which ought to give a handsome income to the land-owner, as the lessee told me that he had paid R10,000 for his 1-5th share of the gems dug out of the above mentioned pit and others during two years' working.

I was asked to go down the rope into one of the mines, but declined with thanks, when I was told that six men were buried alive on Everton by the roof of a tunnel falling in: this would not have prevented me, however, but the slippery mud on the rope.

SOME STATISTICS.

I was then informed that five gallons of oil is daily burned in the lamps used by the miners, and that five bushels of rice were cooked for them daily, besides being paid at rates varying from R1 to 25c each. It also costs over R20 per diem to keep the water down, and R3 worth of rope only lasts for two days; it is being steadily manufactured at the mines. I saw them at work during both my visits in the usual primitive way. The mine owner remarked to me that he thought a chain would be more economical, but he did not think his men would like to work with one. Small tunnels are driven into the shaft to admit light and air,

HANDAPANELA.

I was told that accidents sometimes happen by large rocks rolling down on the top of men who employ themselves washing out the gravel or sand in the stream after heavy rain, where they sometimes come across good catseyes washed down from the forest above, Handapanela, the lease of

which is now offered for sale for gemming purposes, for five years, by Government. Only cats eyes are found in this forest near the surface, but doubtless other gems would be discovered deeper down.

ABANDONED PITS REOPENED.

When passing through Everton Estate, I observed a number of abandoned pits being reopened, so that the whole Gap looks like a fishing village with so many ships' masts, yards, and stages formed by the machinery used by the natives for taking up the water. It is an upright pole with a beam lashed to the top; to this at one end is an upright stick used to fasten the bucket and at the other end is a lot of stones to act as a lever balance and weight, to help the man to bring up the water. This contrivance is rather amusing and ingenious. Sometimes a man is to be seen running along the yard, as it might be called, from one end to the other, as the water is being brought to the surface, if the barrel is a large one. Some of the old pits run into each other and cause disputes as to who is to work them: of course the landowner is called to the rescue, whose decision is final and binding. The whole of Everton Gap presents a very wild aspect, between a background of very precipitous rocky forest and scrub on the one side, and a network of abandoned gem pits and subterraneous passages, enough to frighten anyone to look into them, on the other. I should not care to be the owner of the herds of cattle to be seen about there, for they cannot very well increase in number with so many traps, but it is wonderful how the animals manage to avoid the holes.

THE INTEREST IN GEMMING

is extending in the Morawak Korale. I hear that Mr. Perera, Justice Dias's superintendent, was lucky in finding a good gem the other day, and intends prospecting further. It is said that some parts of Mr. Dias's property are very rich in precious stones, as well as many other parts of the Morawak Korale district; so that some anxiety to begin on their own hook is showing itself amongst the residents.

VALUABLE FINDS.

A splendid catseye and sapphire were found in a pit on Aberfoyle estate, long noted for its large and pure sapphires. I heard, that £5000 was refused for the gems, and that the pit had only cost the five partners a few bushels of rice each, besides the usual ground rent of £10. On Aberfoyle the digging is mostly surface work, no deep shaft sinking has been attempted like that on the Everton side. Success can hardly be depended on in washing the "illian" found only a few feet deep, and it becomes, therefore, more or less gambling. Those who sink deep shafts don't consider the surface "illian" worth wasting time and labour upon.

SALE OF GEMMING RIGHTS.

I hope the gemming right over the 400 acres of land to be sold by Government will not be longer delayed than necessary, to give time for communication with London people, as the whole land has been overrun by illicit gemmers for many months past, who have, it is said, found some magnificent catseyes, and it is well-known that some wealthy native gemmers applied for the land, as well as Europeans, long ago. There will doubtless be strong competition for it.

NOTES FROM LOWER MATALE.

September 12th.

The abnormal weather of this year has amply compensated for the losses of the last, by

reason of the long-continued spells of dry weather, and tea is now seen at its best, in the low flat lands round about Matale and Ukuwala. Mr. Hodgson's clearing with its eighteen months' old field of indigenous Assam is about the most luxuriant growth to be seen anywhere.

Italiadde has changed hands at an advance of the figure it realized a few months back, indicating that a demand for land is setting in just now in that direction. This property will go into tea as part of Mr. E. Storey's clearing.

TOBACCO too has done well in places where the soil was rich and loamy, but chena lands overgrown with lantana do not produce, on being cleared and planted, the same size of leaf as clearings of older jungle growths.

CAO is no new product in Matale and its neighbourhood, but it will grow satisfactorily only in choice spots and under shade. "The Grove" and the "Glen" at Ukawala, new clearings scarcely two years old, have many plants now already in crop. Being of the Foresterio varieties the different coloured pods clinging to the stems of the young trees present a very pretty picture, but the difficulties of the first year or two are never absent anywhere and gaps are always visible in the best planted fields of cacao. If cacao planting may be treated by the enthusiastic gardener as a fine art, quite apart from its financial and grosser aspect, then verily it is a "joy for ever." The same acre will answer the demand over and over, monsoon after monsoon, and give the planter his opportunity for indulging in the pleasant occupation of supplying, shading, hunting for white ants, staking and so forth. But once established, shaded with jak or the wild fig, which ultimately fertilize the ground for the cacao, a steadier and less troublesome product there is not to be found. Then also it is a joy for ever.

PEPPER has proved a great success in the district. But its planting is not taken up with earnestness owing to the success of the other products.

MESSRS. J. S. FRY & SONS have taken a portion of old Bristol Gaol for their ever-growing cocoa business.—*Chemist and Druggist*, Aug. 24th.

THE AUERBACH QUININE-WORKS have made a profit during the financial year 1888-9 of 184,126m.—9,263l.—*Chemist and Druggist*, Aug. 24th.

FARMING IN CALIFORNIA.—M^{rs}. Modjeska adds to her other accomplishments that of being, if not a skilful, at all events a lucky farmer, for her ranche in California is turning out splendidly. Fortunately, as it happens, she and her husband Count Bozenta, did not plant vines, and so have escaped the terrible pest which, it is thought, must have been imported from Australia, and which is devastating the Californian vineyards. Their oranges, walnuts, and olives are all doing splendidly.—*Globe*, August 23rd.

GEMS IN CEYLON.—The *Sunday Times* of Aug. 25th has the following:—

A recent arrival from Ceylon brings news of the discovery of "gem-pits" in that island so productive that a European syndicate has been formed to take them over from the present holders and work them under the name of the "Ceylon Gemming Company." An alexandrite, that beautiful sherry-coloured stone that shines pink by gaslight, said to be valued by its possessor at £25,000, is one of the latest products of these "gem-pits." What a fascinating word that is! And how delightfully suggestive of Sindbad and Rasselas, the Epicurean, and the Seven Champions, and of, in fact, any of the stories of j-wel-treasure. As the alexandrite is of a green colour by daylight and dark red by artificial light, the writer's "sherry-coloured stone" must be something else.

Correspondence.

To the Editor.

CEYLON TEA IN SWITZERLAND.

819 Neuwiesen-Strasse,
Winterthur, Aug. 30th, 1889.

DEAR SIR,—Will you please add my name to your list of benefactors of the Ceylon Tea Industry. Last winter I had the pleasure of staying in your island, and since July 1st. I have begun business on my own account, one branch of my line of business being the sale of genuine Ceylon tea. The majority of the population of Switzerland preferring by far coffee to tea, the results obtained by me so far, are not great, but I hope, that this will improve. If you wish, you may ask information of my character from Messrs. Volkart Brothers, through whose medium I buy my tea.—I am, dear sir, yours truly,

CHARLES OSSWALD.

[Mr. Osswald's name will be added to our published list. He sends us a copy of his German circular "On Ceylon Tea and on the Use of Tea in General," in which a sketch is given of the rise of the tea industry in Ceylon, directions are given for the keeping and preparation of tea, and an extract is added from Dr. Wiel's "Dietetic Cookery Book for the Healthy and the Sick," consisting of some remarks on tea.—Ed.]

CEYLON GREEN TEAS IN AMERICA.

Colombo, 9th Sept. 1889.

DEAR SIR,—I was much pleased to learn, from Mr. Deane's letter appearing in a recent issue, that his green teas, are so favourably reported on from America, fully confirming the opinion I expressed at the time of manufacture that they were teas possessing a character especially suitable for the American taste. Beyond reporting on and classifying the teas in question and pointing out any little defects they had, I had very little to do with the favourable result obtained. I certainly gave Mr. Deane a full report on the tea quite in a business way, but beyond this the entire credit is due to Mr. Deane himself, who was wonderfully successful in obtaining from the first what was wanted in green teas for the American market. In fact I may say that in the whole course of my experience of the trade I have not come across green teas with a better cup character than that possessed by Mr. Deane's Kintyres. Without Mr. Deane's permission, which I hope for the information of his brother planters he will accord, I cannot of course send you a copy of the report on his teas. I may however mention without any breach of confidence that I have received samples of similar teas from several other planters, and that I have, in my reports, strongly recommended the parties interested to make a small break of similar teas with a view to testing the market.

Speaking generally the green teas I have seen in Ceylon have been a much greater success from Olongs.—Yours faithfully,

F. F. STREET.

PADDY CULTIVATION IN THE MATARA DISTRICT.

Matara Kachcheri, September 9th, 1889.

SIR,—As being of public interest in connection with the recent discussion as regards the possible profits of paddy cultivation, I have the honour to annex a statement showing the results of cultivation of 3 fields which entered into competition for the

prizes offered in the enclosed notice published in September 1888. I attribute the absence of competition to indifference on the part of the headmen.—I am, sir, your obedient servant,
H. P. BAUMGARTNER, Asst. Govt. Agent.

NOTICE.—PRIZE PADDY CULTIVATION.

With a view to encourage improved systems of paddy cultivation, sums of R100 and R50 are offered as *First and Second Prizes* respectively, for the largest yield in bushels per acre from any extent of paddy land in the Matara district, cultivated for the forthcoming Yala harvest. Any system of cultivation may be adopted and any description of paddy be sown.

CONDITIONS.

1. The extent cultivated shall be not less than one acre.
2. Within ten days from the date of sowing competitors shall give notice to the Assistant Government Agent of their intention to compete and shall state the name and extent of land sown.
3. Not less than five days prior to the date of reaping, competitors shall furnish the Assistant Government Agent with a statement in writing giving the name, situation, extent and boundaries of the field to be reaped, the date on which it is to be reaped, and the name and place of abode of the proprietor or cultivator.
4. No second prize will be awarded if there are not three or more competitors.
5. Any competitor disregarding, or committing a breach of, the conditions will be disqualified.
6. The Assistant Government Agent with the District Mudaliyars shall form a Committee for the purpose of ascertaining the yield of competing crops and of awarding the prizes.
Their decision on any matter of dispute to be final.

SUGGESTIONS.

Experience has shown that the yield is always increased by the use of the Howard's Cingalee plough (which will be lent on application to the Assistant Government Agent) in the preparation of the soil when dry, and if the field be afterwards cross-ploughed when wet with the native plough.

An interval of not less than six weeks should be allowed to elapse between the completion of ploughing with the improved plough and the commencement of cross ploughing with the native plough.

If in addition to the above process in the preparation of the soil, the paddy is planted out, instead of sown broad cast, the yield will be still further increased.

H. P. BAUMGARTNER, Assistant Government Agent.
Matara Kachcheri, 3rd September 1888.

RESULT.

No. 1.—Competitor: J. P. Gunatilaka; land Otuirikonda in Kapuduwa; extent cultivated: 4,640 square yards or about 1 acre; reported ordinary yield per acre 12 bushels or six fold;—method of competition in cultivation, planted out not sown broad cast;—competition yield: 40. 1. 6.;—competition yield per acre: 40 bushels.

No. 2.—Competitor: Don Dines Abeyegoeratne; land: Neluwala in Siyambaladuwa; extent cultivated: 5,650 square yards or 1 l. 6th acre;—reported ordinary yield per acre: 30 bushels or 15 fold;—method of competition in cultivation: partly planted;—competition yield: 54. 1. 0.;—competition yield per acre: 46½ bushels.

No. 3.—Competitor: Vidane Arachchi of Godagama; land: Tota Kumbure in Hittatiya;—extent cultivated: 2,610 square yards or about ½ acre (half was entirely damaged by flood);—reported ordinary yield per acre: 20 bushels or ten fold;—method of competition in cultivation: planted out;—competition yield: 15. 2. 4.; competition yield per acre: 30 bushels.

No manure used in any of these fields, nor extraordinary expenditure incurred, except on account of the additional labour required for planting.

H. P. BAUMGARTNER, A. G. A.
Matara Kachcheri, September 9th.

THE COTTON INDUSTRY.

Such industries which are dealt with elsewhere as coal mining, iron manufacture, steel manufacture, and engineering and building, employ almost exclusively male labour; even mining, in which, in spite of strenuous endeavours by well-meaning philanthropists to the contrary, females are employed upon the surface, the female labour only represents between one and two per cent. of the total persons employed, being about 10,000 in 600,000. But in the cotton industry the great bulk of the people employed are females, and it is well for a district like Lancashire there should be side by side with industries for men means of occupation for women. In a very able paper on cotton machinery (and the cotton industry is widely different from iron and steel manufacture and mining in respect to the amount of machinery employed; in cotton practically everything is done by mechanical appliances; the hands employed become mere supervisors of the work that is being done) by an eminent Lancashire man, Mr. John Platt, of Oldham, he gives some remarkable figures showing the progress made in cotton manufacture during the century commencing 1760. In that year, the total value of cotton yarn produced was £200,000 as against £85,000,000 a hundred years later. In 1760, the total weight of cotton imported was 3,870,000 pounds as against 1,083,000,000 pounds in 1860. The value of one pound of No. 42 yarn in 1760 was ten shillings and eleven pence as against eleven pence a hundred years after. The value of one pound of No. 100 yarn in 1760 was thirty-eight shillings as against two shillings and six pence in 1860. In a century the value of yarn produced per year increased 425 times, the weight of cotton imported per year increased 285 times, and the selling price per pound of yarn was reduced from twelve to fifteen times. The total number of spindles employed in the cotton manufacture of Great Britain was given in the latter year as 36,000,000, increased to the present time, 1889, to about 42,000,000 spindles; and taking them as spinning on the average No. 32 yarn, when each spindle produces 22½ hanks of 840 yards each, this would represent a regular production of 64,000,000 miles of yarn per day of ten hours when in full work, or a length of thread equal to more than four times round the earth every minute. To this we may add nearly 20 per cent as the increased development up to the present year, 1889. An eminent friend of the writer and a large cotton spinner puts the quantity much higher than given here, and estimates our present power at considerably greater even than we have given it. We employ in the United Kingdom, in the cotton industry, over 500,000 people, which is within measureable distance of the 600,000 persons employed in the mining. We have more spindles at work than all the rest of the world combined. We have in the United Kingdom over 42,000,000 as against 23,000,000 on the Continent of Europe, and 23,000,000 in America.

The raw cotton comes to us directly from the United States of America, the crop of which, probably, exceeds that of all other countries put together. The cultivation of the cotton plant in America has attained its present magnitude in less than a hundred years, and is at the present time expanding very rapidly; the area of land now under cultivation being near upon 20,000,000 acres. In a favourable season this would represent a crop of 10,000,000 bales, and in an unfavourable season 5,000,000 bales free and, consequently, more intelligent labour is now employed; cotton planters, met by the energetic competition of Northern immigrants, who have settled in great numbers upon the cotton

lands of the South-Western States, have put forth new energy. Better systems of cultivation have been introduced, fertilisers are extensively employed, and the production of lint per acre, which had fallen to an average of 150 pounds, has steadily risen until it has now reached 200 pounds. The processes which cotton undergoes in the place of its growth are—*First*.—"Ginning," which separates the fibre from the seed of the plant, and partly cleanses the fibre from foreign matter. *Second*.—"Packing" or "Baling;" after "Ginning" fibre or lint is in a loose state and unfit for convenient transport to distant markets; hence it is necessary to compress it into less space, which is ordinarily performed by means of hydraulic presses. The package leaves the press in the well-known form technically called a bale, in which state it passes through the markets to the hands of the spinners. *Third*.—(and now we come to the actual operations of the cotton mill.) "Mixing," which is the blending of different varieties of raw cotton in order to secure economical production, uniform quality and colour, and an even third in any desired degree. Even when using only one class or variety of cotton, mixing is, in a measure, imperatively necessary in order to neutralise the irregularities of growth and imperfect classification found more or less in all grades of cotton. *Fourth*.—"Willowing," which is a process of opening and cleaning, although not very general in modern mills, is retained chiefly for opening and cleansing low cottons. *Fifth*.—"Opening." In consequence of the heavy pressure to which cotton is subjected in packing, the fibres become strongly matted together; the opening process is to loosen them, and to remove the heavier portion of the foreign substances that may be intermixed. *Sixth*.—"Scutching" has a two-fold object, namely, the further extraction of impurities and the formation of a "lap," which is a web or sheet of cotton formed in the machine and wound upon a small roller. In this web the fibres lie in all directions. All the operations hitherto named deal with cotton in the bulk. *Seventh*.—"Carding," in which the process of opening is continued, but the material is treated in its individual fibres, which are taken from the lap, further cleansed, and laid in a position approximately parallel to each other, forming a thin film, which is afterwards condensed into a silver—a round, soft, and untwisted strand of cotton. In this process all short, broken and immature fibre is, as far as possible, removed. *Eighth*.—"Combing" is used for the production of fine yarns of those of high quality; the object is to obtain uniformity in the length of the fibres undergoing preparation. To accomplish this all those shorter than the required standard are combed away and rejected. *Ninth*.—"Drawing," in which operation several slivers—the product of the carding process—are combined, and attenuated to the dimensions of one of the component parts. The objects are to render the new sliver more uniform in thickness, and to place the fibres more perfectly in parallel order. *Tenth*.—"Slubbing" is a process by which a further combination of slivers is effected, and the objects of drawing are more perfectly accomplished. The drawing or attenuation of the strand is now carried so far that it becomes necessary to twist it slightly in order to preserve its cohesion and rounded form. *Eleventh*.—"Intermediate" or "second slubbing" is in all respects a repetition of the above, necessary in cases where the most even and clean form is required. *Twelfth*.—"Roving" is a continuation of the preceding, its principal object being to attenuate the sliver still further. At this point also the

latter receives additional twist, to enable it to bear the slight strain necessary to draw it from the spool or bobbin without the formation of uneven places. *Thirteenth*:—"Spinning," which is the concluding process of the series. The sliver is here attenuated to the required fineness, and is given the twist by which the thread is completely formed. *Fourteenth*:—"Doubling" is sometimes a separate business but more often an adjunct to the preceding and is a method of combining two or more threads to form a single cord and is adopted in the production of many varieties of yarn which are used for widely different purposes. The processes which we have thus briefly recommended, constitute the operation of cotton spinning. In the paper already referred to by Mr. John Platt of Oldham (and few men were better qualified to speak upon the subject, his firm and family are largely identified with cotton machinery now and their connection with the cotton industry historic), he divided cotton spinning into three distinct operations namely, *First*:—"Drawing," in which the fibres of the raw materials are drawn out longitudinally so as to lay them all parallel with one another and overlapping at the ends, as was done by the fingers of the hand spinner for forming a continuous silver out of the short fibres lying irregularly in the bundle that is tied upon the distaff. *Second*:—"Twisting," in which the silver previously formed is twisted into a roving or thread, for giving it longitudinal tenacity by increasing the lateral friction between the fibres, as was done by the hand-spinner by twisting the bobbin on which the portion of the thread already twisted has been wound. *Third*:—"Winding," in which each portion of the thread, after it has been sufficiently twisted, is wound upon the bobbin. In the application of machinery to the performance of these three operations, the great difficulties experienced have arisen from the irregular character of the cotton fibre on the one hand, and on the other from the unyielding action of the machinery, which has had to take the place of the delicate feeling of the fingers in hand-spinning, whereby the spinner was enabled to accommodate the action continually to the variations in the material. It is a point of special mechanical interest, however, to note at how early a period in the application of machinery correct ideas were developed as to the principle in the important successive steps, so correct, indeed, that they have remained unaltered in principle up to the time Mr. Platt was speaking in 1866, and his statement will, probably, be equally true now in 1889, although many highly ingenious improvements, in detail have subsequently been effected.

The floor space for a mule containing 1,000 spindles will be 116 feet by 10 feet. The cost of a modern cotton mill for spinning No. 32 yarn, including building machinery, and accessories, steam engine and shafting, with fire-proof floors in the scutching and carding rooms, and timber floors in the spinning rooms, was put at 18 shillings a spindle. The amount of thread which a self-acting mule could spin was as much as could be produced by 3,000 hand-spinners.

Now just a word or two about the processes which follow spinning, which may or may not be carried on at the same establishment, namely, weaving, under which the yarn which has been spun is converted into cloth, and which further processes represent weaving. Unlike the spinning, which is carried on in a building several storeys high, weaving takes place in a shed, as much of the work as is possible being carried on on the ground floor. The weft yarn, or that which is laid transversely in the cloth, leaves the mule in the condition in which it is required at the weavers'

loom, but the twist or warp yarn passes through several preparatory processes to fit it for the operation in the weaving. *First*:—"Winding to take the yarn from the top and place it at the warpers' bobbin. *Second*:—"Warping or beaming to wind the yarn from 400 to 500 bobbins to one large beam. *Third*:—"Sizing, which is covering the warp with an adhesive preparation to fit for standing the strains in weaving. No process is more important in the weaving mill, and on it depends the quality and quantity of the work turned off, and, probably, the success of the concern. In sizing the objects are to press into the thread a mixture of suitable ingredients, so as to strengthen the yarn, smoothen it, and lay the fibres which project from the surface of the thread, thus increasing the strength, and, at the same time, reducing the amount of fluff at weaving; and to give the yarn and cloth the requisite appearance of toughness, strength in body, known technically as the "feel." It is in the sizing that the "boardy," "leathery," "clothly" feels or grips are produced. The percentage of size put on cotton goods is calculated according to the increase of weight in the warp only. Thus, if the warp in a piece of cloth be composed of ten pounds of cotton covered with four pounds of size, the warp will have been sized to the extent of 40 per cent. The amount of size on cotton warps varies from 3 to 20 per cent. *Fourth*:—"Attaching the healds and reeds to the warp, called looming or drawing in. *Fifth*:—"Weaving, and about this we will only say that it is the last process in the manufacture of cotton goods and the one in which all the previous ones culminate. It has for its object the combination of the warp and weft yarns interlacing one with the other in such manner as to produce a firm texture, fitted for the varying uses to which cotton cloth is adapted for warmth, for ornament, for trade purposes, for sale. —*Indian Engineer*, Aug. 21st.

THE RED ANT.

From the proceedings of the Natural History Association of Bombay as given in the *Times of India*, we quote a graphic and most amusing account, by Mr. E. H. Aitken, of a species of ant well, but not favourably, known in Ceylon. The red ant, which is so ready to sacrifice its life when enraged, is really very tenacious of life. Seeing a stream of these active, angry and virulent creatures going along the top of a fence, we divided the body of one at the waist, which is exceedingly minute. For an appreciable period the moieties did not seem to be aware they had been parted. A recent letter from Stanley stated that in Africa red ants are a chief ingredient in poison for arrows. Mr. Aitken's paper is as follows:—

The ways of this remarkable insect are not so well known as they deserve to be. Most of us have made its acquaintance at times in the jungles, but these casual introductions have left no desire for closer intimacy. I think, therefore, that a short account of the red ant at home, unillustrated by live specimens, may be interesting. The insect I mean is about half an inch long, and of a light red or orange-brown tint. Its scientific name is *Camponotus smaragdinus*, or "the emerald ant," and Kirby says it is remarkable for its green colour. The explanation of this is probably that the first specimen which found its way to Europe was a queen, for she is green, and is a handsome and striking insect. We are more concerned with the worker, and may stick to our familiar name. The red ant, then, is not a house ant. It does not enter our dwellings and plunder our stores. Neither is it a ground ant. It makes neither burrows nor hills. It is entirely arboreal, making its nest among green leaves, which it draws together with a material like silk, or cobweb. As to its food, it seems, like most ill-tempered people, to need very little. I have

never seen the red ant storing anything, but they swarm about corinda bushes during the fruit season and often enclose the berries in their leaf cells. They do the same with other fruits, and I have seen them in attendance on aphides. But it would be rash to infer from this that they subsist on nectar and sweets. A friend of mine, and a valued member of this Society, had a tame eagle killed by them, and that it was killed for the table admits of little doubt. I believe they devour young birds and every other living thing that falls in their way and cannot escape. Considering how few trees on the western ghats are free from them, it seems a wonder that birds can find places to build their nests. From what I have seen I am inclined to think that a good many nests are deserted on account of them. The red ant appears to be as active by night as by day. This is a point in which the various species of ants differ very much from each other. Some never come out of their holds at night, while some regularly retire for a siesta at noon, and doubtless some are wholly nocturnal. But that which distinguishes the red ant from all other ants, and indeed from all other livings, is its temper. The shepherd in *Noctes Ambrosianæ* says that the wasp is the only one of God's creatures which is eternally out of temper; but the shepherd did not know the red ant. Nor did I till lately. I thought I did, and by painful experience too, I had often had reason to notice how they appear to have intimation beforehand of your intention to pass that way, how they run down every branch that stretches across the path, and wait with jaws extended, how they fling themselves on you, or drop from above, and scorning to waste their strength on your hat or clothes, find out the back of your neck, and bury their long sickleshaped mandibles in your flesh; but I lately discovered that all this was only the A. B. O. of their ferocity. One evening I found that a countless multitude of red ants had collected about two trees close to my tent, and were making a thoroughfare of one of the ropes. I thought it best to discourage this, so I got some kerosine oil, the best antidote I know for insect pests of every kind, and dipping a feather into it, began to anoint the rope, thinking in my simplicity that they would not like to cross the oil and would be obliged to find another road. There was a perfect storm of indignation. They rushed together from both sides, and threw themselves on the oiled feather in the spirit of *Meltus Curtius*. They died of course, but others came on in scores, panting for the same glorious death, and I had to give up my idea of dislodging them by kerosine. I determined then to try tobacco, for I had always supposed that man was the only animal which could endure the smell of that weed. I lighted a cheroot, and steadily blew the smoke where they were thickest. Never in my life have I seen anything like the frenzy of passion which followed the first few puffs. To be attacked by an enemy of which they could not lay hold seemed to be really too much for them. In their rage, they laid hold of each other, and as a red ant never lets go, they were soon linked together by head, legs, and antennæ into one horrible, red, quivering mass. I left these, and, going to another place, offered the end of my cheroot, with about an inch of ash on it. Several seized it instantly. The heat killed them, but others laid hold of their charred limbs, and by their united strength they positively wrenched off the ash, which remained hanging from the tent rope, by their jaws, while scores hurried from both sides, with fiendish fury, to help in worrying it. I then presented the hot end. The foremost ant offered battle without a moment's hesitation, and perished with a *fizz*; but another ant another followed, and I saw plainly that I was beaten again, for the cheroot was going out, while their fury only burned the more fiercely. I retired, and, after taking counsel with the captain of my guard, made a torch of straw, and patiently smoked them to death all along the rope. Then I attacked the root of the tree where they were thickest, and left nothing but a black waste. Half an hour later fresh myriads were carrying off the charred remains of their comrades. They took

them up the tree towards their nest, whether for food or burial rites I cannot say. It was now getting dark, so I gave up my enterprise; but before going to bed I brought out a lantern, and found them calmly passing up and down my tent ropes as before. I had done everything I could short of burning down my tent, and they remained masters of the field. It may interest members of the Anthropological Society to know that the jungle people in the Unara District eat the red ant. They take down the whole nest, and, pounding ants and larvæ together, make them into curry. The blood, or juice, of the red ant is, as might be expected, intensely acrid, and it is said that the fumes which rise from them as they are being pounded make the eyes of the operator smart, so what the sensation of eating them must be is, scarcely thinkable. It must be like a torchlight procession going down one's throat.

The following is from an exchange:—

According to a recent letter from Mr. Henry M. Stanley, the "arrow poison" used with deadly effect by the natives of the Lower Congo district is made of dried red ants, ground into powder, and cooked in palm oil. The irritant effect of this preparation is produced by formic acid, which, in its pure state, is so corrosive that it causes blisters on the skin.

CEYLON TEA FOR THE RUSSIAN MARKET.

Next to the English there is no nation in Europe or indeed in the world who patronize tea, and appreciate good tea, so fully as the Russian. The estimates of the consumption of tea in Russia vary from 72 to 120 millions of lb. per annum and consumption is steadily on the increase. The difficulty of arriving at an exact estimate is due to the variety of ways in which tea enters Russian territory. A great deal—indeed, probably, half—of the exports from China for Russia are conveyed overland via Siberia, while besides shipments to both Baltic and Black Sea ports like Kronstadt and Odessa, there is a further quantity sent to Russia through Germany. A few years ago it was stated on official authority that Russia spent as much as six million pounds sterling for her yearly supply of tea. Here then is a field for the consumption of a large quantity of our fine Ceylon teas which especially deserves to be cultivated. But as yet there has been no systematic attempt made to gain this market, worthy of the name. We are indebted to Sir Graeme Elphinstone for personal visits paid to St. Petersburg and Moscow and the distribution of samples some years ago; but we do not know that his action has been followed up by any regular business. Now, however, we have a much readier means of touching and testing the Russian market through the residence at this port of a Russian gentleman, Agent for the Russian Volunteer Fleet as well as representative of his country. It is a matter of surprise that the Ceylon Tea Fund Committee have not ere now been in communication with M. Edmond de Frisch on the subject. We have ascertained that M. de Frisch is quite ready to assist the Ceylon Tea Planters through their Tea Fund Committee by making known the virtues of our teas in Russia and to push the same through mercantile agencies in the principal markets. M. de Frisch could send on any samples placed at his disposal by his Company's

next steamer, the "St. Petersburg," which calls here about the 27th November on her way from Saghalien to Odessa. Messrs. Zinzinoff Brothers on Moscow, to whose discretion some of the samples would be consigned, are among the most important tea firms in Russia. Of course, M. de Frisch will be ready to ship consignments of tea for sale, as well as samples, and indeed he is personally interested in starting and encouraging a trade in tea between Colombo and Odessa; because the Administration Board of the Russian Volunteer Fleet would be greatly pleased if one or more of their steamers could load up for Odessa at this half-way port every year with tea, in place of going so much farther East to Hankow. We trust, therefore that the enterprising Chairman and Secretary of the Planters' Tea Fund will be able through M. de Frisch to make a wide distribution of representative samples of Ceylon tea with average values f. o. b. noted on the same to aid the Russian dealers in giving orders for shipments by successive steamers of the Volunteer Fleet. One drawback to the trade is the heavy Russian import duty on tea. In the latest annual Report of Messrs. Gow, Wilson & Co. the duty is given as varying from "2d(!) to 11½d," but "1s 10½d from European frontier. M. de Frisch states, however, that the duty "was about 63 copeks in gold or about 1s 8d per lb. last year," and he thinks it must still be the same. This is very heavy, although, of course, if the same duty applies to China as to Ceylon tea, the latter will rather have an advantage.

CEYLON TOBACCO IN GERMANY. FAVOURABLE REPORT.

We are indebted to Mr. Gray of Galmadua, for the following encouraging report on Ceylon tobacco, Mr. Gray writes:—"I enclose a copy of a letter from Bremen about my recent lot of tobacco, and you must bear in mind, this was my first attempt and I had almost all Dumbara tobacco, not having been able to procure good seed, and having 3 months dry weather to contend with. You will especially note that the tobacco was properly cured, and sound, which is the great point, as everybody said I could not find out the curing of it. What does 's' stand for, and how much is it per lb. I would like to know." [What looks like "s" must really be "d" and stand for "pennings," 100 of which equal 1 mark or shilling, so that 45 to 80 per ½ kilo would equal about 5d to 9d per lb. These were the bids, the sale was at 80 p. or 9d per lb.] We quote the Bremen report as follows:—

BREMEN, 20th June 1889.—Confirming our letter of 29th ult. as per duplicate enclosed, we have the pleasure of advising the sale of your 105 bundles tobacco p. st. "Nürnberg" at 80* per ½ kilo at six months credit. As regards the out-turn of the tobacco we beg to say the following:—

There is no essential difference between the six marks, although the S. L. V. L. especially the III. and the one bale V. are somewhat better than the rest, and therefore our remarks apply to the whole of your consignment. The tobacco has, as a novelty, found much interest and a very different valuation, the bids varying from 45 to 80* per ½ kilo: *the favorable attributes of the tobacco are good taste almost equal to Havana, good burning, and good sound condition, the quality is rather too heavy, a lighter one would suit better for cigar purposes, the defect of the growth are the many coarse, thick leaves contained in the assortments I. and II. which cannot be used as wrappers, but only as binders of rather undesirable sorts and therefore the assortment III. and IV. are more useful and valuable than I. and II. For the whole the lot represents no more than cigar binders and fillers, the small percentage of leaf suit-*

* "s" written in translation sent to us, but should clearly be "d."—Ed.

able for wrapper contained in I. and II., and somewhat more in III. cannot be considered, it would be necessary, as soon as larger quantities are raised, to separate the fine leaf from the coarse and thick leaf in order to secure a full value for the former. What our manufacturers want and what they are willing to value high is tobacco of fine silky broad leaf, light of weight and light coloured, and we hope you will succeed in improving your crops in that direction. We don't know the cost of your production, but as labor in India is cheap, as compared with Sumatra and Borneo, we hope that the price of "80" will at least cover your expenses and be no hindrance to further production. Your tobacco has rather too much quality and green, the soil is probably too rich and heavy and perhaps you could counterbalance that by using the seed of a light tobacco as Sumatra Lankat, but in this respect you know certainly more than we.

As regards the packing of your tobacco we recommend to put it in squared bales of about 130 pounds of this shape  and be careful in selecting the leaves according to size, texture and color giving numbers for the different sizes with counter marks in regard to texture and color and one or more main marks for the lot or lots. However, assorting should not be extended more than necessary; many marks force more samples, bales to be opened, more samples to be drawn and valued, they cause more labor and expense and consequently our dealers prefer to buy large lots which can easily be handled. Your first shipment was not in a merchantable condition for a dealer and therefore was only a purchase for a manufacturer of this city; we should, however care to have the competition of the whole market. The buyer has not yet received the tobacco, generally four weeks for storage are allowed, we will settle the business as soon as possible and in our next mail report, you will find sales and remittance for net proceeds. Against further shipments of tobacco you may draw on us at three days or any longer sight with list of weight and shipping documents attached; marine insurance to be covered by us.

TANNING AN ELEPHANT HIDE.

It weighed about 1,200 lb., and was about an inch and a third thick. After being put into a reservoir of pure water to green it, it was beaten for one hour every day with an iron on a large anvil. After being ten days in pure water it was left for another ten days in water with about 4 per cent of salt. Then it was replaced in pure water again for twenty days. During those forty days it was constantly in soak. The head and feet, weighing about 300 lb., were then removed, and the skin hung on spikes in the drying-room. After hanging one day it was put in a vat containing potash and a small quantity of sulphate of sodium in the following proportions: water, 1,000 parts; slaked lime, twenty-five parts; potash, three parts; sulphate of sodium, two parts. After being two days in this bath it was rinsed in pure water of a temperature of twenty degrees, when it was again placed in the drying-room. After this double operation was repeated three times the skin was ready to have the hair taken off. This operation occupied about one day's time and gave about 75 lb. of hair. Another day was spent in cleaning and scraping. By this time it lost 30 per cent of its weight. The operation of its preparation lasted two months, and it went through the same course as cow hide, with the difference that each phase of the work took three times as much time. The skin should be stretched in the pit, and placed in the middle of cow-hides. Six layers of powder are then thrown in; two first, two seconds, and two third layers. Altogether the tanning takes three years. The partition of time is thus: becoming green, 40 days; worked, 16 days; preparation, 50 days; repetition, 60 days; first pit (double), 200 days; second pit (double), 300 days; third pit (double), 400 days.—P. M. Budget.

FRUIT &c., IN NATAL.

(From the Annual Report of the Durban Botanic Society for the year ending Dec 31, 1888.)

Natal Botanic Gardens,
Durban, January, 1889.

The Litchi tree flowered well, and promised a good crop of fruit, but eventually the outer skin cracked, the fruit fell off, or was attacked by the "Peach moth" (*Eggybolis Vaillantiana*), and was sour and uneatable; the failure also of the Sapodilla to set its fruit may perhaps be partly attributed to the same cause.

This is the so-called "Mahogany" tree of the Transvaal and Delagoa Bay districts. It is a leguminous plant, yielding a valuable wood; the seeds also are said to contain an oil, and are thought by the natives to be poisonous; they are black, with a scarlet base, and several are contained in a hard woody pod. Our plants are healthy, but apparently of but slow growth.

The "Toon" tree or "Singapore cedar." It reaches a height of 200 feet, and yields a wood which is valuable, and susceptible of a high polish, it is easily worked, and is used for cabinet work of various kinds. Our plant was put out in 1886, and is now about six feet high.

Oreocentia cujete. Jamaica. Calabash tree.

The hard shells of the fruit of this tree are used by the natives of tropical America for a variety of purposes, and are often carved and polished, taking the place of crockeryware; the pulp of the fruit is used medicinally. Our plant is now about four feet high, and growing fairly well.

Melia azadirachta. India. "Margosa tree."

This is the tree which in India is called the "Neem," or "Margosa" tree, and a kind of toddy is extracted from it by tapping; from its fruit an oil is obtained, which is said to be valuable. The plant has grown well, and seems to be as much at home here as its near relative, *M. azederach*, the so-called "Syringa."

This handsome banana reaches a height of about 30 feet, with leaves occasionally 20 feet in length and 3 feet wide; the fruit, however, is pulpless and uneatable, it does not produce suckers, and having flowered, and ripened its seed, it dies, and can only be reproduced by seed.

Musa textilis. Manila.

The plant which produces the "Manila hemp" of commerce. Our plant looks well, though stunted in size, and gives offsets, but all yet planted out have died; but in pots, with the shelter of the fernery, it grows slowly.

Pinus sinensis. China. Chinese pine.

A fine tree reaching 30 to 40 feet high, which is being planted extensively in some places; it is said to prefer a sandy soil, is a good tree for avenues, &c., and the wood is valuable. *P. Massoniana* is said to be a synonym, but our plants look as if they belonged to different species; the one we have as *P. sinensis* is however certainly correctly named.

Piper nigrum. E. Indies. Pepper plant.
" betel " " " " betel leaf "

The last-named two plants are alive, but not flourishing. I fear that the soil of the Gardens is not suitable for them.

Pongamia glabra. E. Indies. Tree.

A leguminous tree, from whose seeds an oil called "Poonga oil" is extracted. It has been recommended as an avenue tree, and seems likely to succeed well here. It was planted out in 1886.

Swietenia mahagoni. W. Indies. "Mahogany."

I am glad to be able to say that these plants are doing fairly well; they were planted at the end of 1886, and the largest one is now over six feet high. The plant which was known as the "Mahogany" when I took charge of the Gardens in 1882, flowered, and turned out to be a species of *Spodias*, of no special value.

Chlorocodon Whitei "Umondi."

The young plants which we had on hand when my last Annual Report was written, were all given to Mr. Parsons, of Wentworth, who is giving them a trial. The plant apparently grows fairly well even

in the sandy and poor soil of the Berea, though no doubt it would thrive better in moister and richer ground. Our plant has flowered, but, I fear, will not mature seed. I am informed that there will most likely be a large demand for the roots if they can be produced in quantity. Small samples are of no use whatever, especially if the continued supply is uncertain.

Lime Juice.—The bottles of Lime Juice forwarded to England, as stated in my Report for 1887, reached home safely, and the following report on the article was received:—

"We have examined the four samples of Lime Juice sent us by you. They are uniform as to test and general appearance. This juice has evidently been filtered, and is very clean, and free from all deposit. We think the lime Juice Cordial manufacturers, amongst whom Messrs. W. Rose & Co. are one of the largest, should give a good price for a parcel similar to these samples, and we should recommend your submitting them in one or two quarters. For citric acid manufacturing the value to us would be only about one-half of what we expect you would get from the above direction. Should you at any time recommend your correspondents to concentrate juice for citric acid manufacturing, please advise them that 64 ounces of citric acid to the Imperial gallon is the most suitable strength. When concentrated juice is of a much higher strength, the cost of working is greater."

The firm to whom I sent the samples, and who obtained the above report, say:—"You will see that it is reported upon as being a very high class product; and we should be glad if you could get anyone to prepare it in this form, and we would take charge of the shipments, and we are in touch with most of the purchasers of this product." They also say:—"The Lime Juice is so good, it is ready for domestic use; so a friend reported on 'change who had tested your samples."

Gomphocarpus sp. "Itshongwe."—In my last report I stated that roots of a species of *Gomphocarpus* had been purchased for and forwarded to Messrs. Christy & Co. It is quite probable that under the name "Itshongwe," the natives include a *Xysmalobium*, as well as one or more species of *Gomphocarpus*. The alkaloid from the roots of these plants was first extracted by the late Mr. Jocelyn Cooke, of Estcourt, who strongly recommended it as a remedy for fever. On examination in England the alkaloid was reported to be probably new, but not of the quinine type, and larger quantities were required for experiment, which I obtained as stated above; and in a recent letter they say:—

"This is now being thoroughly gone into in France by an eminent chemist and physiologist. We hope to publish some illustrated matter upon this same subject very shortly; but so far as we can find out, the properties of the active principles of this root do not appear to be of very great interest or novelty in medicine."

Colpoon compressum, "Bergbas."—Constant enquiries are being made about the leaves of this plant, which are said to compare favourably with "Sumach," but I have not heard that any further attempts are being made either to collect the leaves, or to cultivate the plant. It is a native of the upper districts, and is, I believe, very common in some parts of Cape Colony, Free State, and Transvaal. I have collected specimens of it in Alfred County, and also on Noodsberg.

Manihot Glaziovii "Ceara scrap."—The plants of this tree, which were reared from cuttings, are now forming a thick bush, but I fear will not grow into good trees. It is in my opinion a mistake to propagate the tree by cuttings, seed alone should be used; and I am informed by Mr. A. Wilkinson, to whom young plants were supplied, which are now bearing seed, that if the outer shells of the seeds be cracked with a small hammer before planting, they will germinate as quickly as though the edges of the seed were filed in the usual manner, which is rather a tedious process, and without some precaution of this kind the seeds may lay 12 months or more in the ground before germination takes place. Our plants now

bear seed in abundance, which can be had on application by any person wishing to cultivate the plant. A small quantity of rubber was extracted, and has been forwarded to Kew, but it is after all but a sample, and a much larger quantity would be required before any reliable report could be obtained about it. There is no doubt whatever about the suitability of the plant to our soil and climate.

Morus alba.—We received a small packet of seed of this plant, which is said to be the best mulberry for silkworms, and a few plants were reared, the whole of which were handed over to a gentleman living near Durban, who is interested in sericulture.

Tristania conferta, "Box tree" of Brisbane.—This tree appears to thrive well in the Gardens, and is in my opinion a very suitable tree for coast planting. It is handsomer than a "Gum," though it does not grow so fast as some of the Eucalypts, but it has one great advantage—the white ants do not touch it. Our trees have already borne some seed, and plants have been reared, which will be ready for distribution next spring. It is said to be an eligible avenue tree, and its timber is good and durable.

Banana Disease.—The disease or fungus alluded to in my Annual Report for 1886 has now nearly destroyed the patch of bananas in which it appeared. I visited the place more than once, but was unable to detect any fungus. I therefore had two of the young plants brought here and planted in the Gardens, so that I might observe them more closely, but so far they remain quite healthy, and though they were taken from an infected stock, no sign of disease has as yet appeared on them. I shall, however, continue to watch them with interest.

Sutherlandia frutescens, "Cancer plant."—I fear that investigations and experiments made with this plant have shown, that beyond having some little tonic properties, it is of little if any use as a remedy for cancer—a fact much to be regretted.

Aloe sp., "Isiputamana."—When in Zululand in the early part of the year, I received from the Rev. R. Robertson a plant of a species of Aloe, the flower spike of which is used by the natives as a vegetable. I also collected four plants of the same species, one of which was in flower. I therefore had the flower spike cooked, and I found it delicious. Since then I have obtained several other plants, some of which are now coming into flower, and I hope to be able to obtain seed from them for distribution. Two of the plants were sent to Kew Gardens, and in acknowledging their receipt, Mr. D. Morris, Assistant Director, says:—

"The species of Aloe, the flowers of which are used as a vegetable is certainly a novelty. So few Aloes possess anything but medicinal value than an Aloe, which is a pot herb, deserves some notice. The two stems reached us in good order, and we hope to grow them on and flower them at Kew. We could then determine whether they are new species or not."

Jacaranda mimosoformis.—This plant has again flowered, and been much admired, and I have received, by the kindness of Mr. Soutter, of Brisbane, who saw my notice of the plant in the Report for 1887, a packet of seed, from which plants have been reared, which will shortly be available for distribution.

Sapota achras (Syn. *Achras sapota*).—Though this plant flowered freely, it did not set a single fruit. I regret this the more, as the fruit is said to be delicious, and would be a welcome addition to our list of fruit trees. Our plant is not in a good condition; but we have one or two small plants which will be planted out next spring, or as soon as we have a piece of ground cleared to receive them. It is known as the Sapodilla plum.

Haloxylon ammodendron.—Seeds of this plant were received from Kew. It is said to be a "small tree native of dry and arid regions of Turkestan. Useful to grow in sandy and droughty places, where other trees and shrubs fail;" but I regret to have to say that, though every care was taken of them, not a single seed has germinated up to date.

Fodder Plants.—In my last Annual Report allusion was made to several fodder plants, seeds of which

had been distributed from these Gardens, and further information about them was promised. All the species have been grown here, and also by other persons to whom seed was distributed, with the following result:—

Eragrostis abyssinica, "Teff."—As a cereal in Natal this plant will, as I suspected, have no value; but very favourable reports have been received of it as a quick-growing fodder grass. I distributed the whole of the seed, except the small portion which was planted in the Gardens, and hope that some of the recipients will be able to use it profitably.

Lespedeza striata, "Japan clover."—This plant has also done fairly well in the Gardens. We had but four plants the first season, which died down apparently without producing any seed; but in the spring it came up thickly, and formed a small but dense mat of foliage. I am inclined to believe that it propagates itself by small bulblets, which are produced on the roots in great abundance. During the winter months, therefore, it is not available; but as a change of food for sheep in summer I do not doubt it will have some value. I believe it has succeeded equally well near and beyond Maritzburg.

Cytisus proliferus, "Tagasaste."—These plants have done well in the Gardens, and some have been distributed to correspondents; but it is rather early yet to give any further report about them.

On the coast the plant grows splendidly, and I hope it may succeed equally well in the upper districts, especially as it is available during the winter months. A correspondent in Madeira writes:—"I hope your *Cytisus* plants will grow properly; they grow at 3000 feet in the island of Palma, and afford food when everything is dried up."

Pithecolobium saman, "Rain tree."—As a suggestion was made in one of the local newspapers that this tree should be introduced into the Colony, it may be as well to repeat here that we have the plant in the Gardens, but it does not seem to thrive well. Plants have been reared for distribution, should any one care to give them a trial. The pods are said to be an excellent food for cattle, and the tree forms a good shade, and grass grows freely under it; but its rain-producing powers have been greatly exaggerated, the reason being, I believe, that the tree is sometimes infested by an insect of the Cicada family, which at one period of its existence secretes a fluid, which falls to the ground in large drops, thus suggesting the idea that the leaves distil water from the atmosphere, hence the popular name "Rain tree."

Fibre Plants.—Once more I venture to call attention to some of our native plants, which have been proved to yield valuable fibre, in the hope that ere long this industry may become established in the Colony.

Gomphocarpus physocarpus.—The fibre from this plant has been frequently sent to me, and many years ago I myself prepared specimens for exhibition. In the early part of the year I received two samples, one from Mr. John Duan of Zululand, and one from Mr. Plaxton Harrison of Durban, the last one prepared by a new process. These samples were forwarded to England for report. The brokers to whose agent I gave a portion of the first-named sample, say:—"We have pleasure to advise you that there would be a ready market for this Hemp if it could only be produced in fair to large quantities, and be cleaned free from the bark or husk, of which your sample contains so much. We find the colour and strength both very good, and we could dispose of large quantities of this fibre at about equal to £25 per ton c. i. f. London, if it could be cleaned as stated above. If the hemp could be produced a foot longer or so, it would be more valuable. The great beauty of this hemp is its exceptional strength, and no doubt if it could be produced in large enough quantities, and the length increased, it would sell quickly and equally well with Manila Hemp, the present price for which is say £33 to £34 per ton." The remainder of Mr. Duan's sample, and also that from Mr. Harrison, were forwarded to Kew; and Mr. D. Morris, the Assistant Director, says Mr. Duan's sample:—"The fibre from Zululand, which we have accepted as derived from *Gomphocarpus physocarpus*, is evidently possessed of merit, and we forwarded

a sample of it to Messrs. Ide & Christy for valuation and report. Of course you noticed that the specimen was in a very rough state, and very indifferently cleaned. Hence the brokers report, which I enclose, is not conclusive as to the value of the fibre, if carefully and fully cleaned, and presented at its best. In this, as in most fibres, the whole thing turns on questions of quality and quantity, and whether it can be placed in the market at such a price as will compete with fibres already well known, and with an established reputation." Of Mr. Harrison's sample he says:—"In their present condition they are useless for textile or ropemaking purposes. The only use to which they could be applied in this curled up crushed state is for paper-making." The brokers report on Mr. Dunn's fibre is as follows:—"This is so imperfectly cleaned that the full merits of the fibre are apparently not disclosed, and in its present condition it would only be available for cordage purposes, or as an adulterant of, say, Manila or other white hems of commerce. The fibres apart from the adherent tissue, which would be removed under better preparation, are of excellent colour, but the strength is rather disappointing as compared with Manila. From the different character of fibres obtained, from endogenous and exogenous plants respectively it is always difficult to estimate their relative strength otherwise than by taking a given weight of each, and placing them on a testing machine, that would properly record their breaking strain."

"We estimate the value of the *Gomphocarpus* fibre in its present condition at £15 per ton, but through cleaning would probably enhance its value 75 to 100 per cent. It is probable too that perfectly prepared fibre would find its best market as a material for textile purposes, as a supplement to flax, but we should like to see a thoroughly well-cleaned specimen before giving a definite opinion."

With respect to length of the fibre, I may say that in my opinion there would be no difficulty in increasing it considerably, provided the plant was cultivated, the specimens sent were prepared from wild plants, which of course are liable to branch repeatedly, and this would not take place if the plants were grown thickly together. The matter of more complete cleaning must be left for further experiment.

Urera tenax. "Umbogozembe."—This plant has now been specifically named, and proves to be a new species, but I have not heard that any person is as yet propagating it for the purpose of extracting the fibre which it contains, though I believe it would under favourable circumstances, be a paying industry. It is a perennial shrub, and is easily propagated from cuttings, which take root easily. Samples of fibre can be made by any one, but to obtain a good reliable report as to its value, it should be sent home in bulk, and not as mere samples.

Cannabis Sp. "Native Hemp," "Insangu."—I do not hear that anything has been done to produce this fibre in fair commercial quantities. Of its value there can, I think, be no doubt, and it is somewhat disappointing to find that its cultivation on a reasonable large scale has not yet been attempted.

We have then three indigenous plants, the fibre of each of which has been favourably reported on from time to time, and still no one seems willing to lead the way in introducing an industry which could hardly fail eventually to give fair if not large returns, and to considerably swell the list of our exports.

Fibre Machines.—In September last a trial of improved machines, intended chiefly for stems of "Ramie," or "China grass," was held in Paris, and Mr. D. Morris, of Kew, attended, together with "representatives from all parts of the world." Prizes had been offered by the French Government, and the entries consisted of 19 machines and 10 chemical processes, but on the morning of the trial only four machines and one chemical process were submitted to the jurors. Mr. Morris's report was published in the Kew Bulletin for November last, and it will not be necessary for me to do more than quote the concluding paragraph as follows:—"It is quite possible that some machine or process will eventually solve the problem, but at present the exploitation of 'Ramiel,' in spite of years of labour, and the expenditure of large sums of money upon it, cannot be said to have yet emerged from the experimental stage."

THE MAGAZINE
OF
THE SCHOOL OF AGRICULTURE,
COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for October:—

HOW DOES SCIENCE HELP AGRICULTURE?

IV.

By C. DRIEBERG, B.A., F.H.A.S.

Geology as an aid to agriculture treats of rock formation and the history of soils. All soils have been formed out of rock, by the process of weathering, which may be described as the work of the agents which assist in breaking up rocks and making them suitable for plant food and for fixing the plant. The weathering agents may be classified as follows:—

I. Mechanical agents such as (1) glaciers, (2) stones and sand rolling down river beds and helping the water to produce greater erosion, (3) waves and tides, (4) sand blowing against the face of a rock, (5) wind, (6) rain drops.

II. Chemical agents as (1) oxygen, (2) water as a solvent, (3) carbonic acid in water, (4) the juices of plant roots.

III. Thermometric agents as (1) frost, a most powerful disintegrating agent, (2) heat.

IV. Animal agents as earthworms, &c.

The interesting manner in which each of these agents works—some, such as, earthworms doing an amount of work, which few credit them with—cannot be gone fully into in this series of articles, for it is not intended at present to bring together all the interesting facts which the sciences contribute to agriculture, but merely to indicate how they do help, and in what branches of agriculture they step in as auxiliaries.

When it is said that soils are derived from rock it is not to be supposed that where a certain rock formation prevails, there a particular soil must characterize the locality, though this is exceptionally the case. In the latter instance, when the soil or weathered

rock is found to overlie the living rock from which it was derived, we have sedentary soils; while in the former, that is where the soil has no great resemblance to the underlying rock, and does not suggest that it was derived from it, we have transported soils. Transported soils are such as have been brought from a distance by various agencies, such as:—(1) glaciers, (2) the sea, (3) rivers, (4) wind, (5) volcanoes.

The organic portion of rock in soil may have been derived in many ways. In the organically formed rocks—limestone for instance—we can understand how the remains of the organisms which help to build up the formation contributed a supply of organic matter. In a similar manner the remains of fossilized plants and animals add organic matter to rocks to some extent. In soils the growth and decay of generations of lower vegetable organisms have furnished the necessary supply for plants of a larger growth. Beginning with the lowest forms of vegetable life these accumulations have gone on till natural forests have been enabled to thrive luxuriantly.

Knowing therefore the composition of rocks, or rather the composition of minerals forming the rock, we get a fair idea of the composition of soils. Knowing also the history of a soil (as we should from a knowledge of geology), that is the manner in which it was formed and left where we find it, we get a still better idea of its nature and character. And thus we get information of economic value, for we will thus be able to decide what crops should be cultivated on certain soils, knowing what conditions both as regards mechanical texture and chemical composition favour particular families of plants. Again we would have a general idea as to what manures, if any, we should add. Where, moreover, we have facilities for studying the stratification of a country by means of the information supplied by

a geological survey, there will accrue a vast amount of invaluable knowledge to agriculture as well as to many other industries. To the agriculturist a knowledge of the sub-strata of his land will be of great value; helping him to find out the nature of the formations beneath, and whether any are absent; the dip of the beds and their thickness, as well as the arrangement of the permeable and impermeable strata.

Information of this nature will help him in such operations as drainage, irrigation, and water supply.

LIFE-HISTORIES OF INSECTS INJURIOUS TO VEGETATION IN CEYLON. III.

By ABA.

Having explained the general principles of Entomological science in the previous articles, I will now proceed to discuss the classification of Insects. Linné in his *Systema Naturæ* divides all insects into seven great orders, viz: *Coleoptera*, *Hemiptera*, *Lepidoptera*, *Peuroptera*, *Hymenoptera*, *Diptera* and *Aptera*. Several modifications were proposed by Leach and other authors, but the classification, adopted by Prof. Westwood in his "Introduction to Entomology," which divides all insects into thirteen orders is accepted on all sides as the most simple and comprehensive system. In the words of Miss Ormerod the thirteen orders are "arranged according to general similarity in the early stages, and also in the general appearance of the perfect insects composing each order; also according to the number or nature of their wings, or the method in which they are folded beneath the wing-cases."

These thirteen orders of Westwood are divided into two great tribes named *Mandibulata* and *Haustellata*. To the firstnamed tribe belong the insects which feed by means of jaws (Mandibles) such as the Beetles, &c. To the second belong the moths, butterflies, aphides, &c. insects which feed by means of a kind of sucker (haustellum).

With regard to the nomenclature of the orders it will be noticed that the last part of the name of each order is *Ptera*, which comes from the Greek word *Pteron*, a wing, while the first part describes the nature of the wing, for example, Coleo—(sheath) ptera (wing) the order of beetles.

The following list of the orders of insects is taken from the "Manual of Injurious Insects" by Miss Ormerod:—

Mandibulata.

- Coleoptera*.—Sheath-winged. Beetles.
- Euplexoptera*.—Lightly-folded winged. Earwigs.
- Orthoptera*.—Straight-winged. Cockroaches, crickets, grass-hoppers, &c.
- Thysanoptera*.—Fringe-winged. Thrips.
- Neuroptera*.—Nerve-winged. White ants, May-flies, Dragon flies, &c.
- Trichoptera*.—Hairy-winged. Caddice-flies.

Hymenoptera.—Membrane-winged. Saw-flies, Gall-flies, ants, wasps, bees, &c.

Strepsiptera.—Twisted-winged. Bee parasites. *Hanste'llata*.

Lepidoptera.—Scale-winged. Butterflies, Moths.

Homoptera.—Similar-winged. Aphides, Scale-insects, &c.

Heteroptera.—Dissimilar-winged. Plant-bugs, &c.

Aphaniptera.—Imperceptible-winged. Fleas.

Diptera.—Two-winged. Gnats, Gad-flies, Bot-flies, Flesh-flies, &c.

(To be continued.)

NOTES ON SOME OF THE GEOLOGICAL FORMATIONS IN CEYLON.

By C. DRIEBERG, B.A., F.H.A.S.

Clay, a common formation in Ceylon, is a product from the decomposition of highly felspatic rock such as granite. It consists mainly of silica and hydrated silicate of alumina with also variable proportions of other ingredients. Taking granite as a source of clay we observe that it is formed mainly of three minerals: quartz, felspar and mica. Quartz is nearly pure silica; felspar is essentially composed of silica, alumina and potash; while mica may be generally described as aluminous silicate containing potash. Now, in all these minerals there is a large proportion of either silica or alumina or both. In the process of decomposition of the granite the silica and alumina unite to form silicate of alumina and become further hydrated by the addition of water. The two latter being the least soluble, are left as the ultimate products of decomposition, while the other ingredients of quartz, felspar and mica are carried away in solution. Clay then consists as before stated of the hydrated silicate of alumina with such other ingredients of the original minerals as have not been carried away in solution. Where the result of decomposition is almost altogether silica and hydrated silicate of alumina, we get kaolin or China clay and pipe clay. Potters clay contains more impurities than these, while brick clay again consists of a mixture of finely-divided clay and sand together with iron. Fire clay contains little or no lime and other alkaline earths, or iron, which under the influence of heat act as fluxes, and would thus unfit the clay for the purpose it is intended to fulfil. Iron ore abounds in certain clay deposits as clay iron stone, and also appears often as nodules in combination with earthy matter. Mr. A. C. Dixon observes that in decomposing, they produce a rock identical with laterite or cabook. These nodules I observed present to a large extent in the red clay soils near Matale, some of them evidently containing very large proportions of iron, judging by their great weight. Clay slate is a clay deposit which has undergone great pressure, and splits readily into thin plates or slabs; it is found of a variety of colours. The clay state group is included in the metamorphic system together with gneiss and mica-schist.

After the disintegration of the original felspatic

rock by the atmosphere and water, we must assume that the undissolved materials were carried by water acting as a transporting agent, and then allowed to settle down in some quiet sea: that the sediment in time became consolidated into clay rock, and finally that heat, pressure, chemical force and such metamorphic agents produced the crystalline structure and induced the property known as cleavage in slate. In fact, it has been found by experiment that cleavage may be induced by pressure alone. As would be expected from its association with gneiss and mica-schist, the clay state group has been much contorted and upheaved. The economic uses of clay slate are as roofing material, writing slate, slate-pencils and for ornamental and architectural purposes. The group is often traversed by metalliferous drains. Clays themselves assume a variety of hues—the yellow and red colours are due to the presence of iron. The dark clays of our agricultural soils, generally contain various other ingredients, besides silica and silicate of alumina, and notably potash, which is contained both in felspar and mica; and it is the presence of this important element of plant-food which makes clay soils so valuable. Moreover, their peculiar mechanical consistency makes them absorbents of the valuable gases in the atmosphere. But on this subject of soils and their properties, I hope to touch on another occasion.

Clay used for brick-making and for pottery were near Jaffna, Matale, in Alutkuru Korale, near Cotta, Moratuwa, Panadura and in the Rayigam and Pasdun Korales, and very generally in the Galle district; also at Kottiyaram is a specially good pottery clay deposit; other places are Porativue and Panduruppu near Batticaloa, Navagamua near Colombo and Tulpawela near Matara. Kaolin is obtained at Gangodawila and Nuga-goda near Cotta, Ambagamua and Maturata among other places.

PADDY CULTIVATION AND TRANS-PLANTING. III.

BY W. A. DE SILVA.

(Continued.)

Planting Out.—Meanwhile, the field should be well prepared to receive the plants from the nursery. The practice common amongst the cultivators of paddy in Ceylon is to plough and puddle to bring the land into a muddy condition with an even surface. They have not got a system of thorough tillage and exposure of the soil; the only end the cultivators look to is the effectual putting down of the weeds and bringing the land into as fine a state as possible. In most places these last two operations are done very effectually, and fields prepared for sowing are the result of much care and industry, and show what the *goyias* could do in their own way. The levelling and draining are done with quite an engineering skill. But these operations are done, as it were, in one groove and never show improvement or extension. This must evidently have been due to a want of encouragements to improve. It is seen from the arts of husbandry amongst the

goyias that they kept pace and even outstripped the rest of the world in improvements at a certain period, which is evidenced from the ancient Irrigation works, &c., and after reaching a certain point in their improvements, they stopped short, and of course where there is no improvement a gradual degeneration is the consequence. The reasons for the non-furtherance of improvements may be traced to the want of attention paid to their concerns from higher sources. The internal troubles in the Island at certain periods were the cause of diverting the attention of the rulers from the concerns of the peasantry. During these troubles the Kings and Ministers had more to think of their immediate security of person and authority than of the poor peasantry. This brought on the stagnation of their prosperity and nay degeneration itself. Where are the vast expanses of cultivated areas spoken in history? The people who once lived in plenty had to experience a gradual decreasing until their fields began to produce hardly sufficient for their maintenance. Since the settlement of the political affairs after the British occupation, the *goyias* are having attention paid to their concerns. Though their prosperity declined rapidly, it would take years and years to bring them at least to their old condition. The descent is rapid, but the ascent is difficult. So with the attention paid to the native agriculturist at the present day in our Island, we have one comfort that they will slowly but steadily improve; that their granaries will once more be full, and their fields will smile with plenty.

The two operations mentioned by me, namely, the destruction of weeds and the bringing of the land to a fine condition, have always been done by the *goyias*, and at present are the two essential operations in the cultivation, the neglect of one of which might tell severely on a crop. But two more operations are generally neglected by them to a more or less extent; they are thorough tillage and exposure. These two are essential for the improvement of a crop and are more advanced operations. The *goyias* do not understand the nature of the results which these operations will lead to in improving the land: neither the action of the air, nor that of sunlight are understood by them. I shall pass over these two operations, and deal with them under the subject of tillage, and will at present treat of the subject of transplanting.

In the field well prepared by thorough tillage, destruction of weeds and the levelling of the surface, the young plants should be planted out. The plants should be taken when they are from 3 to 4 weeks old, and those which have not grown well should be cautiously avoided. It is better not to plant at all than plant weak plantlets, which cannot hold themselves up. They not only die off after unsuccessful attempts to grow, but injure their neighbours, in giving facilities for the spreading of weeds. I will here say a word about the limitation of the age of plants. Too young plants when planted out are not hardy enough to hold themselves up, and hence the

weeds work harm by checking the growth and reducing the crop. Again, plants when too old, have hardly time to grow in the field; they waste their time and energy in a packed-up nursery, and have hardly time to establish themselves well and give out shoots. So, great care should be exercised in choosing out good plants of proper age.

After the plants are pulled from the nursery, their tops as well as the roots should be cropped—this not only makes them handy for the transplanting operation, but prevents their falling down, and their remaining leaves withering—; growth begins at once, without waiting for the drying and decaying of the leaves if any were left.

The proper distance for planting out is from 4 to 6 inches apart. One should be guided in fixing the distance by the variety of paddy used and the richness of the soil. When the variety takes a longer time to produce and the soil is rich, the plants should be thinly put in, but when the plants take less time to produce and the soil is not very rich, they should be put in closer. Those varieties which take a longer time to yield will have time to grow and give out shoots, and this is facilitated in a rich soil; but where the reverse is the case, the plants should be put closer so as to avoid unoccupied spaces which encourage the growth of weeds.

It is stated that the paddy cultivators of Guiana put down two plants together and place each couple nine inches apart, but the varieties they use are early ones, or those taking a less time to produce. The same system may be adopted here with early varieties, but it necessitates two weedings instead of one, because, much vacant space is left at first, the weeds start growing early. (The cost and additional labour entailed in transplanting and its practicability will be discussed at length further on.)

(To be continued.)

COTTON. III.

BY ABA.

Whatever may be the merits of our climate with regard to its favorableness for the growth of cotton, it has been the opinion of many that Ceylon does not possess suitable lands for the cultivation of the plant. The late Dr. Kelaart writing in the year 1854 says that the peculiar soil of the Madras Presidency called "regur" commonly known as the "black cotton soil" which overlies a limestone gravel called "Kunkur" is not found in the Island. The learned Doctor has made a mistake however, for I came across a black soil similar to that of Madras, and accompanied by beds of limestone in the North-Central Province during a recent vacation tour.

Besides the black or so-called cotton soil two other kinds of soils are recognised in India as suited to the growth of cotton, viz., the red and the alluvial soils, and it has been found by experience that the red soils are more suited to the growth of the better varieties of cotton than the black soils. At Matale and

Maradankadawala I saw cotton growing remarkably well on red soil.

With regard to climate it may be laid down that extreme wet and extreme dry are both unfavorable to the growth of cotton. The cotton plant is a dry weather crop, and the largest returns are obtained in dry years. Heavy rain such as fell during the month is very destructive. There should be just enough rain to soften the land for ploughing. Then a shower or two to help the seed to sprout and make it grow, afterwards occasional rain until the plants have grown sufficiently to shade the ground.

(To be continued.)

CATTLE-DISEASE IN CEYLON.

BY C. DRIEBERG, B.A., F.H.A.S.

Medallist, New Veterinary College, Edin.

The report of the acting Sanitary Officer, and the remarks of the Editor of the *Ceylon Independent*, on certain diseases in cattle prevalent in the Island, raise the question: Why is not there a competent person to enquire into the subject of cattle-diseases in Ceylon? The observations and experiments of eminent Veterinarians and Medical men in Europe have established the fact, that there are certain diseases in cattle that are transmitted to men, such for example as tuberculosis. Apart from this important consideration, there are diseases which carry off numbers of cattle in the Island, of the nature and treatment of which nothing is definitely known. Is it not an anomaly, then, that in a country where cattle are so largely used for draught purposes, and for milk and meat production, there should be no single qualified person in authority to advise and direct the Government in the matter of cattle disease? During the past month a large number of cattle have been destroyed by an epizootic attack, the precise nature and predisposing cause of which cattle owners seem to have no definite idea of. It has been described as "murrain"—a vague term which seems to be indiscriminately applied to most epizootic diseases in the Island. The term "murrain" has been confined in its application, in western countries to the attack known as "foot-and-mouth disease," but if any distinction is made in Ceylon, this latter seems to be the only affection that is not included in the wide-reaching term "murrain," which seems to indicate all forms of epizootic disease that cause sudden destruction among cattle, without any apparent cause. This, however, is a most unsatisfactory state of affairs, where there is no definite idea of the conditions and symptoms which attend the disease, and no precise knowledge of the *postmortem* evidences, simply because no attempt has been, or is being, made in the direction of gaining such information. Is it the want of a qualified person that causes this anomaly? That is not so, since there has been such in the Island, and no advantage was taken of the opportunity, till his services were secured elsewhere. It is rather that the need of such a person will not be recognised. Now, is there sufficient reason for

omitting to appoint a qualified person whose duty it would be to examine the meat and milk of cattle that are supplied for human consumption, and look for, and try to mitigate, the causes that tend to the production of unsound food which is the fruitful source of disease among the human inhabitants in the Island? None. For when the most eminent authorities have laid down that certain diseases are transmissible from animals to man, and since medical men recognise the existence of such diseases in Ceylon, there is no excuse for failing to provide supervision—the strictest and most searching—over cattle-buyers and slaughter-houses. Time and study are necessary for the practical experience on which such supervision must be based, and it is needless to lean on the excuse that the scraps of attention of medical men, and police and sanitary officers supply the necessary supervision. The matter to be dealt with cannot be so easily or carelessly disposed of. It is a subject which requires close and undivided attention, and a deal of study, existing as it does in a country where circumstances and surroundings in relation to Veterinary Science have hitherto never been disinterestedly or conscientiously considered.

The Congress for the study of human and animal tuberculosis, which met at Paris in July last year, read and discussed a large number of papers submitted by experts from many parts of the world, collated and examined the investigations of many observers, visited hospitals, veterinary schools, and museums of hygiene, examined sick animals, performed numerous *postmortems*, and studied many disinfecting hygienic appliances. Testimony was abundant of the efficacy of antiseptics in checking, or preventing further development of, the disease. Several instances were recorded of the milk of one infected cow, although mixed with that of healthy cows, having communicated tuberculosis. It was unanimously adopted at the meeting that it was necessary to submit dairies to a special surveillance, so that it may be ascertained that the cows are not affected with contagious diseases capable of communication to man.

Dr. Latham in the Harveian oration stated last year that one human being out of every seven dies from pulmonary tuberculosis; and Principal Walley, in his address as President of the Scottish Metropolitan Veterinary Medical Society, stated that tuberculosis was on the increase, and that the possible danger, especially to young children, from drinking the milk of tuberculous cows marked it as a disease with which the Government should at once cope. The danger, says the *Lancet*, would appear to apply much more to the milk, and we must largely trust to the inspection of cow-houses and dairies, which it is to be hoped will before long eliminate from amongst those cows which supply milk for human consumption any that are obviously suffering from tuberculosis.

Professor Williams of the New Veterinary College, Edinburgh, speaking at Newcastle last summer, said that many serious diseases in animals, by proper sanitary arrangements, had been almost entirely got

rid of. Others which still inflicted heavy losses, with proper preventative means, might be exterminated, while intelligent management was destined to abate the severity of others. More knowledge and care on the part of stock-owners, prevention of the use of milk of such animals as were affected, and the condemning of tuberculous carcasses should, in the opinion of the Professor, diminish the occurrence of tuberculosis alike in man and animals.

Last year an eminent veterinarian and an equally well-known sanitarian in the persons of Professor McCall and Dr. Russel were appointed to report on tuberculosis. The following are some of the suggestions contained in their report:—

"Sanitary inspectors act under the guidance of the Medical Officer and Chief Sanitary Inspector. Meat inspectors should in like manner act on the lines laid down by veterinary and medical authorities. Following their general instructions they would acquire practical knowledge sufficient for their guidance. The function of the meat inspector ought to be solely that of detaining diseased or suspicious carcasses until such time as they are inspected by the chief inspector. This chief inspector ought to be either a qualified veterinary surgeon or a medical man. It seems right, considering the important interests at stake, both public and private, that the confiscation should not be left to the judgment of a constable. We propose therefore that for this reason as well as to secure uniformity and efficiency in all slaughter-houses, a chief inspector should be appointed, who, if a medical man, should be attached to the Sanitary Department, and if a veterinary surgeon to the chief inspector under the Contagious Diseases Act. It would be necessary to appoint competent inspectors, and to prescribe rules for frequent inspection for the detection of infected animals. We are strongly of opinion that by some means specific power should be obtained to inspect dairy cattle for detection of tuberculosis, and prevent the use of the milk of affected animals for human food. As regards tuberculosis especially the securing of healthy conditions for cows as regards ventilation and cleanliness is essential to the stamping-out of the disease."

With the foregoing evidence and recommendations before us, there can be but one opinion on this matter: that there is much danger to human beings through cattle-disease, and that this danger can be averted, or at any rate greatly mitigated by supervision by proper inspectors over cattle-sheds and slaughter-houses. Most of the suggestions contained in the report from which I have quoted apply with a few modifications as well to Ceylon as to the city of Glasgow. We should at least have the chief inspector with the necessary qualifications for the desired supervision and study of cattle-disease as it exists with us; and his work will no doubt be the means of raising up slaughter-house keepers of a better class, as well as of instilling a practical knowledge of cattle

pathology and the sanitation necessary in cattle-pens. The present state of cattle sheds and the treatment of cattle kept for milking purposes exhibit an amount of ignorance and carelessness which are dangerous and call for immediate action. The suggestion has been thrown out that a medical student should make a study of the subject of cattle-disease, and fulfil the duties of a veterinary inspector, or chief inspector, or superintendent of cattle. If necessary he might take a course of instruction in one of the Veterinary Colleges in England or Scotland for special qualification. The chief point, however, is that there should be a man appointed, unhampered by other duties, to devote all his time to the study of comparative Pathology, and thus qualify himself for the important task of detecting those sources of contagion which give ingress to so much misery in the world. And are all these issues to depend merely on a point of false economy? When it is thought necessary that every country district in most western lands should have this supervision, it is time that a not-insignificant Crown Colony should look to supplying the want!

INDIGENOUS FOOD PRODUCTS: CULTIVATED AND WILD.

By W. ARTHUR DE SILVA.

(Natural Order *Nymphaeaceæ*.)

1. *Nelumbium Speciosum*, Willd; Sing. Nelun.—This plant commonly known as the lotus is found throughout the Island. It is an aquatic herb having leaves and flowers growing from a rhizome below water. The petals and stamens are indefinite in number. The seeds are placed in a fleshy receptacle, and they attain the size of about $\frac{1}{2}$ of an inch in length and the same circumference when mature. The outer covering of the seed blackens when ripe. The seeds are used as food in most parts of the Island, and they contain starch. The rhizome also contains a little starch, but is not known to be eaten though occasionally chewed by people for the starch it contains. It is used in native medicines, and is reputed to be efficacious in dysentery and intermittent fever. The seed is generally used as a food after being boiled and seasoned with salt. There is no peculiarity of taste or flavour about it, and tastes like any other boiled starchy seed. It is also eaten along with coconut when the flavour is very agreeable.

The stamens of the flower of this plant are said to possess cooling and astringent properties, and are used in bleeding piles by native Medical Practitioners.

2. *Nymphaea Lotus*, L., Sing. Olu.

This too like the *Nelumbium* is an aquatic plant, but met with more commonly. Its stem (rhizome) grows under water, and the leaves spring as high as the ordinary level of the water in which it grows. The flowers are borne upon a stalk which is longer than the stalks of the leaves. They have a calyx

of four separate parts and an indefinite number of petals and stamens placed upon and around the carpels. There are many carpels and the seeds are numerous. The flowers keep without fading for a number of days; they open in the morning but close in the noon, and do not open again till sunrise the next day. The seeds are very small in size resembling mustard grains both in colour and form, and they contain a large quantity of starch. The seed is generally used as food. When eaten raw it has a good flavour, but it is used thus in very small quantities only. When the plants are abundant, and the seeds largely collected, they are dried and pounded, and a flour is prepared which is used in making conjee and cakes. The dried seed is commonly known as *olu sal* meaning lotus rice, and is boiled and eaten in some parts of the Island, as they use ordinary rice. It is said that village *Veddas* use this as a food to some extent and a poem* current amongst them, describes the process of obtaining the seed.

The rhizomes are starchy and are eaten after removing the outer part which does not contain any such matter. They are generally eaten raw, but are said to be used boiled also in some places. The unboiled rhizomes have a milky taste.

The porous and long stalks of the leaves and flowers are used in curries. They are chopped into pieces of about half an inch in length and boiled in water, after which the water is strained off to remove the peculiar leafy taste, which would otherwise spoil the flavour of the curry. After this process, onions, chillies, pepper, salt, &c., are added as in an ordinary hot curry, and prepared in the same manner when it becomes a relishable dish, and also possesses a healthy action on the system.

The rhizomes are used amongst the Sinhalese in medicine for blood-shot eyes and also to reduce thirst in cases of intermittent fever. An excellent poultice is prepared by boiling *olu* rhizome, rice, and milk which is used in cases of ulcers and sores of a serious nature with good results.

FENCES.

By T. W. GOONEWARDENE.

Fences are in most situations indispensable in the profitable management of land. They primarily protect crops from animals, but are useful in other ways. Often they are the means of preventing the soil from being washed away. They act also as boundaries to separate one piece of land from another. In England where cattle and sheep farming is systematically

* The meaning of the verse which is said to be used amongst *Veddas* is as follows:—"There are good *olu* and *nelun* in Soraborawewa, and the women go and pluck them. They are cleaned and boiled, but no curry is used with them."

carried on, the need of proper fencing is very great for separating the animals into small herds as necessity demands for grazing and other purposes.

The kind and disposition of fences will depend on the natural surface, situations of roads, watercourses, climate, the inequalities of surface, the nature of the soil, the supply of water, and the course of husbandry to be followed.

Among the various means of fencing in land in Ceylon are the hedge, ditch, wall, and paling.

The ditch is the best on low flats, wet land requiring much drainage. The hedge might be combined with this: for after making a ditch round the land, sticks of Erandu, Belipatta (*Hibiscus Tiliaceus*), Pattangi (*Caesalpinia Sappan*) Godapara (*Dillenia Retusa*), Andara (*Dicrostachys Cnerea*), Weraniya (*Hedyotis fructicosa*), Erithryna Indica and Murunga (*Moringa pterygosperma*), may be used.

The planting of the hedge should be done in April and May. The live-sticks should not be kept too long after being cut from the parent tree as they might thus lose their growing power.

Live-fences.—The sticks should be planted from 8 to 15 inches apart, and poles or long sticks of any kind should be tied cross-wise to the planted sticks. This is to prevent the sticks growing in any but the perpendicular direction, for once they get rooted at an inclination it would be difficult to get them straight again. The side branches should be lopped, while those nearest the root should be left to grow. This pruning of the side branches will cause them to send out new shoots from their extremities, and this repeated trimming will make the hedge so thick as to fill up every interstice from top to bottom. The main stem should be left untouched till it reaches the required height, after which it should be kept at the necessary elevation by occasional pruning. In this way may be got the perfect hedge which it is said should be able to "turn a fly and a cow." The leaves of these hedges may often with advantage be used for manuring the land.

Dead-fences.—In this country dead-fences are more abundant than live-fences. In some villages while a part of a field is being cultivated for the Maha harvest the rest lies fallow, to be cultivated for the Yala harvest, and the two are separated by the former being fenced in. As soon as the crop is secured the sticks are pulled up and stored in the shade or under water till they are required again. By following this method the stick can be utilized for 3 or 4 years.

Palings.—This is another means of protecting the land and is generally adopted by estate owners, and especially on sugar-cane plantations. It is a mistake to take any and every sort of wood for this purpose, as durability should be a special quality in the sticks used. Good kinds of timber such as *Milla*, *Weli-penna*, *Bokerra*, or *Wil-aratu*.

If the above kinds are not easily procurable, less durable varieties will have to be used, but after point-

ing the ends of the stakes the precaution should be taken of charring the end as a preventative against decay. The stakes should be driven about 1 foot deep, by a mallet, into a hole made by the foot-pick, at a distance from one another not exceeding 5 to 6 feet. When planted 15 inches below ground they will make the fence stand 3 feet 3 inches high. Rails for fixing on to the stakes may be made from the hardest part of the kital tree (*Caryota urens*), a tree split into eight parts would serve the purpose. To give additional strength to the fence, the rails should be placed on the face of the stake, next the field, and the ends of the rails should not all meet and be nailed to one stake; for instance, if two ends of the top rails meet at one stake, two ends of the middle rails should meet at a second stake, and the two end of the lowest rails should meet at a third stake. Nor should the stout ends of the rails be nailed together even after being thinned flatwise. The upper edge of the lowest rail should be 9 inches from the ground, of the middle 22 inches from the ground, while the highest rail should rest on the top of the stakes. The nails for nailing on are called "stout paling nail, having a length of from 3 to 3½ inches."

SOMETHING ABOUT THE ONION.

The onion is a member of the genus *allium* of the great lily family (*Liliaceæ*) which yields such a great variety of fragrant flowers. The common onion, of which there are a great many varieties produced by cultivation and crossing, is known to Botanists as the *allium cepa*. The native country of the onion has not been exactly determined, some supposing it to be Egypt, and others India, in both of which it has been cultivated from the remotest times. The part chiefly used is the bulb, but the tender leaves are also used. As a flavouring ingredient in cookery there is no vegetable production equal to it. There is no civilized nation on the face of the earth that does not use one or other of the many varieties of the onion. Even savages seem to understand the value of it. In Ceylon the onion is chiefly used as a condiment, also for pickling, but it is said that in Spain and Portugal a raw onion with a piece of bread often forms the only dinner of a working man.

The onion is highly nutritious, and is considered by the natives to be efficacious in cases of nervous prostration, as it is supposed to possess the property of giving a tone to the worn-out system in a short time. The alimentary and medicinal properties of the onion are due to a large quantity of nitrogenous matter and an acrid sulphurous volatile oil. An onion baked under hot ashes and mashed with a little cow's ghee makes a useful emollient and stimulating poultice for suppurating boils, &c. Made into a decoction with the leaves of "gotu kola" *Hydrocotyle Asiatica* it is a household remedy for worms in young children.

Our supplies of onion are derived from India, but

there is no reason why we should not grow our own when the cultivation is so easy. The onion succeeds best in a rich light soil.

The land for the onion crop should be thoroughly prepared either by ploughing or digging and should be entirely free from lumps. The best manure is that which is well rotted and fine, so as to be well mixed with the soil. The sets (small bulbs) should be planted, either in April or August, in rows eighteen inches apart to admit of easy weeding. The sets may be put down four inches apart in the rows and the ground covered with a layer of well, rotted cow-dung soon after planting. Frequent stirring of the soil between the rows during the growth of the crop is beneficial and the land must be carefully kept free of weeds. The bulbs are taken up when the leaves decay and are thoroughly dried in the shade before putting away.

NOTES FROM EXPERIMENTAL STATIONS.

BATICALOA, 31st August 1889.

I am at present starting the work for a new Agricultural Inspector who is expected shortly at Illapayadichenai in the north of Baticaloa. As there is a great demand for "improved ploughs" all throughout the Baticaloa district, the Government Agent has ordered twenty climax improved ploughs from Messrs. Massy & Co.'s at Madras. These are only R6 each there, and not much longer than a month ago we received half a dozen. I am at present occupied with ploughing. At my permanent station some 10 acres are being prepared for cotton planting. The dholl and other plots are in good condition.

S. CHELIAH.

AKMIMANA, 4th September 1889.

The paddy crop of the yala season has been reaped, the results, however, not being as good as was expected. This is evidently owing to the heavy rains we had during the early part of July when the plants were in the flowering stage, as well as the damage done by the "goyan messa" or paddy bug.

Some of the native cultivators have a peculiar idea as to the paddy blight, and asserts that it is due to the results of cutting the grass round the fields with the sickle. They describe it by the word "Dakattapeyannawe." Probably a result of this cutting away of the grass around a field may be to disturb the insects that have been lodging there and send them among the paddy. I am clearing land for cotton, arrowroot and vegetables, and have commenced work in the paddy-field for the "maha" season. The weather is rather dry.

P. SAMARANAYAKE.

KEGALLE, 10th September 1889.

Of the four varieties of cotton planted here, the Egyptian and American are now in bud, while the Sea-Island and Peruvian are yet small plants. The latter, however, look quite healthy with the suitable weather they have had. The native variety of Tobacco, which I have planted to a small extent, seems to thrive well, but the tender leaves are unfortunately being destroyed by some insect. Since my last report, I have laid a small portion of land under arrowroot, and the young plants are shooting up well. English and native vegetable seeds have also been sown with what success I hope to report next month.

I am endeavouring to extend the Experimental Gardens, and have made a new clearing of about $\frac{3}{4}$ of an acre which I intend reserving for dholl.

The weather during August was very wet, with particularly heavy falls of rain during the last fortnight.

J. W. P. SAMARASEKERE.

GENERAL ITEMS.

"It gives me the most profound satisfaction to speak of the noble work being done in Ceylon generally by

Mr. H. W. Green, the Director of Public Instruction, and Mr. E. Elliot, Government Agent in the Eastern Province. Fame is but an empty name, and monuments will decay, but the work these gentlemen are doing will ever remain. The personal attention given by them to self-imposed duties in trying to improve the agricultural interests of the people stands out in such brilliant colours, that one would think that other Government officials in very shame would try to do something to help those under their charge. This is practical good of the noblest kind. May the highest success reward their every effort."—*Mr. Powell in "The Buddhist."* [By the time Mr. Powell completes his tour he will no doubt change his opinion that other Government officials are doing nothing to help those under their charge—especially in the agricultural affairs.—Ed.]

Germany is spending probably not less than £100,000 per annum on agricultural education and experiments.

The reckless destruction of forests in Prussia has⁸ lately increased to such an extent, that the Government has issued a law protecting timber throughout the empire. In recent years this wholesale felling of fine woods has completely changed the climate of many districts, rendering the country barren and rains less. Further, removing the trees from the banks of lakes and rivers has loosened the sand and thus shallowed many harbours and water-courses.

"Tofu" is a churd manufactured from a bean in Japan, and approaches more nearly in its composition to animal food than any other vegetable known. It contains about one-fifth of its weight of fat, and nearly two-fifths of nitrogenous matter, having at least double the nutrient value of beef. The Japanese procure this food by soaking and grinding the beans to a pulp. Water is added, and the liquor is strained through a bag, and brine stirred in. This effects a coagulation, and the curd is pressed as in cheese-making. The fibrous residue left in the bag is mixed with chaff, and used as a food for cattle. The Tofu bean has been lately successfully grown in Germany, but Mr. Matthew Williams, a leading scientist says, that he has treated common split peas in a similar manner, and has obtained soluble casein, which he precipitated with acetic acid. "All kinds of peas and beans," says Mr. Williams, "will yield such soluble casein when thus treated, and most valuable food may be thus obtained free from woody fibre which is different to digest. My experiments point to the possibility of a very important industry in the manufacture of a new and most desirable food, viz., vegetable cheese. If I am not altogether mistaken it may be produced on a large scale, at about three pence per pound, and be equal, if not superior, to the best cheese made in the dairy."

Sixty thousand pounds for thirty acres of land is not (says the Norwich *Argus*) so bad in these times. This was the price fetched at the mart under Mr. A. J. Baker's hammer. Among the property submitted was Kidderpore Hall Estate, Hampstead, lot I (5 acres) being bought in for £10,750. Sir Spencer Maryon Wilson, Bart. the adjoining owner, bought lot 2 (two acres) for £4,300. The mansion itself and thirteen acres fell to Mr. Arthur Yarrow, of Fitzjohn's Avenue, for £43,000 after a keen competition.

Some people doubt the poisonous effect of Nutmeg, but several cases of nutmeg poisoning were noted in the *British Medical Journal* during the summer of last year. A whole nutmeg was taken in four of the cases, and five whole ones in the remaining case. In still another case the use of half a nutmeg in a hot drink was nearly fatal.

COLOMBO, NOVEMBER 1ST, 1889.

[No. 5.

“GREVILLEA ROBUSTA” AN ANTIDOTE TO COFFEE LEAF DISEASE?

THE author of a very interesting account of “A Hot Weather Tour in South India” makes mention in the second part, which we quote below from the *Pioneer* of the “silk oak” as securing immunity from coffee leaf disease to bushes growing within its influence. In no authority within our reach, and we have consulted the Dictionary of Botany, Von Mueller’s Extra-Tropical Plants, and Gamble’s Manual of Indian Timbers, can we find any mention of *Quercidia robusta*. We feel quite confident that the tree intended is the “silk oak” of the Australians, the beautiful and useful *Grevillea robusta*, which has found a second home in the hill regions of India and Ceylon. This tree has no affinity to the true oaks (*quercus*), so that the popular name must have referred to the excellent quality of the timber. We have a very high opinion of this member of the *Proteaceae*, but we have never observed that it prevented coffee bushes in its neighbourhood from being attacked by leaf disease. It is so common on coffee estates in Ceylon that its effects if it have any in this direction must have been observed. Will planters who have coffee and grevilleas growing together kindly let us know if coffee seems benefited. Besides being a good shade tree for coffee, *Grevillea robusta* is said to enrich the soil by the large quantity of leaves it sheds. The extract is as follows:—

A HOT WEATHER TOUR IN SOUTHERN INDIA.

Ruin of the Permado coffee plantations—the silver oak, (*quercidia robusta*), alleged to be an antidote to leaf-disease—coffee cultivation in shade and the bushes allowed to grow unpruned—pepper vines growing on forest trees.

The elevation of the country round Permado is from 3,500 feet to 4,000 feet. Eight years ago it was a most prosperous settlement. There were more than forty planters, each with a thriving coffee estate. Year after year they raised bumper crops, prices were

good, and all went merry as a marriage bell. But “black care” was behind. As Schiller says in the Song of the Bell:—

“But with the powers of weal and woe
No man may bargain here below.”

First prices fell, and then leaf-disease put in its appearance. The trees abnormally crippled and stunted so as to be forced into bearing the valuable seed were more liable to be attacked than if they had been in a healthy condition; the soil was exhausted by all that had been taken out of it, and not being very rich was no longer able to give the trees sustenance. The disease spread from year to year until almost all the plantations were destroyed by it. The planters lately so prosperous were reduced to beggary. The gentleman with whom we stayed, who a few years ago was making a clear profit of £3,000 per annum, told us that two years ago he was almost ruined. His land yielded next to nothing, he had to sell his trophies, his gun and even his pony in order to keep the pot boiling. Instead of keeping three assistants, he had to do the overseer’s work himself. By cutting down a great portion of the coffee and planting out tea he was able at last to get a small return. Last year he just paid his expenses, but this year he hopes to make a fair profit. As regards the others the story is the same. Instead of there being more than forty planters there are now about half a dozen. One man has to look after several estates, instead of having an assistant to help him on his own. Most of the houses are empty and are occupied only during the hot season by visitors from Cochin and Travandrum. Latterly the coffee has shown signs of recovering, and by accident a tree has been discovered which forms an antidote to leaf disease. When laying out his estate the gentleman before alluded to planted avenues of silver oak (*quercidia robusta*) along his roads. When the leaf disease broke out these trees had grown to a considerable height, and it was found that not a single bush beneath the shade of a silver oak was ever attacked by leaf disease. The tree drops an enormous quantity of leaves, and thus not only gives shade, but also manure. The coffee trees beneath do not give such rich crops, but they give a steady return. This gentleman, as also others, are now planting silver oaks amongst their diseased coffee, and by this means hope to get the better of the enemy who almost ruined them. The silver oak may have special qualities, but from what we subsequently heard it is probable that the disease was due chiefly to irrational planting.

Some sixty or seventy miles further north on the same range of hills is a portion called the Lower Pulneys. Here during the last ten years a number of plantations have been started on a system totally opposed to what in most places is in force. Instead of felling the forest the planter simply clears away the undergrowth, and plants his coffee amongst the forest trees. He does not prune or cut the shrubs down, but lets them grow as Nature intended them. Instead of exhausting

the soil and distorting his trees he leaves them to grow up in shade with rich supplies of natural manure, and in consequence he has never been visited by leaf disease or borer, &c., and from year to year produces crops which, though not equal to what is called "bumpers," yield him a very handsome profit. In the *Permade* they are now reverting to this natural order of things, and will we trust find the benefit of so doing. Many of the planters have restocked their estates with tea, but though this may yield a profit now there can be no doubt that the market is glutted, and that a fall in prices may be expected. Besides, the elevation in *Permade* is not high enough to grow the finest flavoured teas. *Cinchona* has also been planted, but the same remarks regarding elevation applies to this tree. It is only in the higher altitudes, and in the richest forest soil, that the bark gains a high average of alkaloids, and it seems almost certain that before long the low averaged barks will be driven from the market because it will no longer pay to produce them. The result will be that *cinchona* will only be grown at high elevations and in the richest soil. Such sites are rare, and will therefore in all probability soon rise in value. Altogether *Permade* did not impress us with the idea that it has a future before it. Indeed it rather seems to be played out. The elevation is comparatively low; the soil seemed poor; the position is exposed to the full force of the south-west monsoon, and the rainfall is about 200 inches per annum.

CEYLON TEA IN SOUTH AUSTRALIA.

The following letter has been sent us for publication by Messrs. Drummond Bros. of Adelaide, with a request that we should support their proposal to represent the Ceylon Tea Fund in South Australia:—

(Copy). Gawler Place, Adelaide, S. A., Sept. 9th, 1889. A. Philip, Esq., Secy. Ceylon Tea Fund, Kandy, Ceylon.

Dear Sir,—As requested in yours of 28th Feb. last, we repeated our application for the agency of the Planters' Tea Fund in South Australia and were fully under the impression that it would be considered at the following meeting; but by *Overland Observer* we notice there is no mention of the matter at the meeting held on 5th July. We would again draw your attention *re* our appointment as agents of the Planters' Association for the sale of Ceylon produce and especially tea which we were the first to introduce into Adelaide direct to the public and we have since made it a speciality. We are establishing a promising business and are supported by some of the most influential people from His Excellency the Governor and downwards. Besides agents canvassing, we have opened a new agency at Gawler, a large township about 20 miles from Adelaide, which we think will answer well. We have a standing advertisement in the local papers and intend to increase the space considerably. In the event of our request being granted, we are fully confident, of an appreciable increase of business. Sincerely trusting the matter will be considered at the next Tea Fund meeting, we remain, dear sir, yours faithfully,

DRUMMOND BROS.

ENEMIES OF THE COCONUT.

A correspondent, who refers to experience in the Eastern Province, writes:—

"Did you get a letter last week telling of the cure I had found out which had proved quite successful, against the ravages of bandicoot rats on coconut trees 4 and 5 years of age. I suggested that they should tar the top of the tree which the rats attacked very freely, and not a rat attacked any tree that was thus tarred. Thus many acres of young trees have been saved and the rats have disappeared."

We referred the matter to our correspondent W. J. at Negombo, who replies:—

"I know nothing of the ravages of the bandicoot rat, and never heard the natives in this or neighbouring districts complain of mischief done by them; perhaps they are not numerous here and affect the dryer parts of the island. I can quite understand that they would do considerable damage to young coconut plants as they are armed with formidable cutting teeth. I have seen a hole eaten through the husk and shell of a perfectly dry coconut and the kernel eaten out; an animal that could tackle a tough job like that would have little trouble in eating into the heart of a young coconut plant. I have not heard of tar applied to the stem being used as a remedy, but if the animal is of a suspicious nature like the porcupine I can quite believe its being effectual if repeated every two or three months."

We should like to know whether any appearances of the so-called coconut leaf disease have been noted in the Eastern districts.

THE CONSUMPTION OF QUININE.

"I never knew quinine to sell so well as it is doing this year," says a St. Louis druggist, "and the boom is not confined to any one locality, as quite a number of houses in the city have run short several times, notwithstanding the abundant supply on the market. The only explanation I can suggest is that people who profess to ridicule physicians because of their overdosing, doctor themselves and fall into an exaggeration of the very errors of which they accuse regular practitioners. If people want to derive benefit from quinine they must use it systematically, commencing with as large a dose as the constitution can safely stand, and reducing it by degrees. Instead of this, most victims to malaria commence with infinitesimal doses, and gradually increase them, the result being that the system gets used to the drug, and the malaria is only checked, instead of being driven out at the start. My favourite prescription for malaria is a concoction of whisky and quinine, one or two strong doses of which will reach any case I have yet met with. And the more rigidly the patient has previously abstained from whisky the more rapid will be the effect.—*Oil, Paint and Drug Reporter.*

A CORNER IN QUININE.

Under the heading of "What might occur in the present peculiar state of the market" the *Financial News* gives the result of some investigations as to the position of quinine. It says there has evidently been a considerable decrease in the import of *cinchona* bark from Ceylon, while the stock in London is comparatively small and of bad quality, and the Java cultivation will not make up for the falling off in the imports from South America and Ceylon. In 1885 quinine was 3s 8d. per oz., in 1886 it was 3s 1d., in 1887 it was 2s 6d., in 1888 it was 2s 4d., and at the present time it is only 1s 2½d. Between now and next December (not including August) already considerably more than half a million ounces of quinine have been sold by the bears. It is a remarkable fact that when there was 50 per cent. more of the raw material to work with the price was three times more than it now is. An authority on the question considers that it does not now pay to manufacture; indeed, he cannot see how it is possible to make a profit on it. He is also of the opinion that there will be a further falling-off in the production of the bark. It is five years before the bark trees are fit for cutting, and meanwhile the demand for quinine naturally increases. He further states that bear sellers, who are almost exclusively German manufacturers, have

been selling to an enormous extent for forward delivery; but when these deliveries became due, by offering a small quantity on the spot at a low rate, they have been able to buy back their own contracts at a considerable reduction on the price at which they sold. This, he adds, has been going on for a considerable time, until now they have brought quinine to its present absurdly low quotation. With regard to the present stock of cinchona in London, on May 31st there were 65,700 packages, against 76,500 on May 31st 1885, showing another falling off to the extent of over 10,000 packages. A great deal of the present stock is also said to be absolute rubbish. A few years ago quinine was selling freely at 15s. per ounce, and there is no reason why it should not be selling at the same price now the consumption is greater. The authority referred to is of the opinion that it is quite possible for a capitalist or a syndicate to acquire the present supply, and, by taking delivery when tendered, create a corner, the effect of which would be largely felt. At the same time he says, there is no possibility of any serious loss to investors at the present price.

WATER FOR TEA OR COFFEE.

All tea and coffee drinkers can tell by the taste if the water from which the beverage is made has not been boiled or has boiled too much. Either of these conditions will spoil the flavor of the costliest tea or the best coffee berry, but not every one knows the reason or how to avoid the result. The secret is in putting good fresh water into a clean kettle already warm and setting it to boil quickly, and then take it right off to use in tea, coffee or other drinks before it is spoiled. If the water is allowed to steam and simmer and evaporate till all the good of the water is in the air, and the lime and iron and dregs left in the kettle, you must not expect a well-flavored cup of tea or coffee. —*Scientific American*.

A COFFEE CONUNDRUM.

The price of Brazil coffee August 9th, 1889, with a stock of 311,635 bags here and afloat for the United States was—No. 7, 10-80 cts. Fair, 14 cts.

Now, with a stock here and afloat of 448,493 bags, it is for—No. 7, 14-95 cts. Fair 18½ cts.

Query: With 25 per cent larger supply, why should prices be 4 cts. per pound higher than last year?

If we take a wider view, the world's visible supply is in round numbers 1,250,000 bags greater than last year at this time.

There are no reliable reports showing that this year's crop is likely to be materially deficient.

How long can speculation dam up the stream? —*American Grocer*, Aug. 14th.

A SUBSTITUTE FOR COAL.

Petrole is the name given to a manufactured substitute for coal, made by a firm in Minneapolis and is the direct outcome of the scarcity of fuel, which has retarded the birth of manufacturing industries in that city, and, in fact, the whole North-West. It is made from sawdust, the residuum of crude petroleum, and a number of other ingredients, which are not made known by the inventors. The residuum of petroleum is mixed with the other material, and is heated in a large sheet-iron tank to 400 deg. Fahrenheit. It is then run into a mixing machine, where it is thoroughly mixed with the sawdust, and is afterward carried by means of a chute to a heavy press, where it is subjected to a pressure of 1,000 pounds to the square inch, and moulded into blocks 10 in. long, 4 in. wide, and 3

in. thick. It is claimed for this new fuel, which has been successfully tested, that it is cheaper, and its results as satisfactory in every way as coal.—*India-rubber and Guttapercha Journal*, Aug. 8th.

COFFEE NOTES.

The prolonged and excessive drouth in Venezuela has had a bad effect on the transportation of coffee to the sea board. In October last the stock at Villanuser awaiting transportation to Maracaibo was 60,000 bags; at the end of April this had been increased to 300,000 bags, the streams were dry and there were then no prospects of getting the coffee out.

According to the *New York Shipping and Commercial List*, June 22nd, a large coffee distributing house had ordered a canvas of a wide section of the West, North-west and South-west of the United States, to ascertain stocks in dealers' hands, etc. The reports are that although stocks are light consumption has been sharply reduced, varying in different cases from 25 to 50 per cent. Tea seems to be the great competitor, but in one case it is stated "the farmers are drinking butter-milk." One report says "that 60 cents per bushel for wheat and 25 cents per lb. for coffee is too great a difference." And we agree thereto.—*Rio News*, July 29th.

A GREEN-TEA STORY.

Some twenty-five to thirty years ago a grocer carrying on business in one of the principal cities of the North of England, says the *London Grocer* sat in the office of a well-known and respected merchant, who, though not a dealer in consumable stores, was ever ready to buy and sell if he could see money in the transaction. The grocer, being in needy circumstances and anxious to dispose of some of his old stock, asked the merchant if he could do with a few packages of green tea if he got them at the right price, adding that he was rather overstocked and was anxious to realize for cash. Gunpowders and hysons, as many of our readers are aware, were at that time at a very different price from what they are now.

The merchant, having only a vague idea of the actual value of tea, inquired from the grocer how much a pound he wanted for it, and asked him if he had a sample. The grocer said he had not brought a sample but would do so in a day or two. On the day following a sample was brought neatly wrapped in a quarter of a sheet of demy tea paper. It was opened and then handed to the merchant for his inspection. He looked at it, turned it over with his fingers, apparently in imitation of an experienced tea-buyer, and asked the grocer how much he wanted for it. "Well," said the latter naming as near as he could the quantity he had, "green teas are worth such and such prices, but being anxious to realize, and knowing that you are always ready to do a good turn for a grocer, I shall be disposed to accept your offer, if it be a reasonable one, as you have doubtless some idea what you can get for it, and of course you expect to get a fair profit." The merchant was flattered by these expressions of confidence, and boldly made an offer, which after very few words was accepted. The tea was duly delivered on the following day, and the grocer immediately presented his account, which was promptly paid after the merchant had examined the bulk and found it equal to sample.

Shortly afterwards another grocer entered the merchant's office. "Do you want any green tea?" said the latter; "I can sell it cheap." "Let me see it," said the grocer, who was somewhat surprised

at being offered tea by one who, he happened to know, had little knowledge of it. Hereupon a sample of the green tea was brought and very carefully scrutinized by the grocer. He remained silent for about a minute or so, during which time his countenance assumed a significant expression, and then he exclaimed, "Where in the world have you got this stuff from, Mr.—?" "Why, what is the matter with it?" "Matter with it!" said the grocer; "you are surely jesting in calling this green tea!" and, taking out his pocket knife, he selected a few of the larger "leaves" and cut them through. The merchant looked on in amazement, and was horrified on being told that old currants dressed with copperas and Prussian blue was a poor substitute for green tea. "Yes," he repeated. "they are shrivelled old currants!"

Finding himself so completely sold, he now concerned himself only about the fact becoming known to the outer world, for he had not only allowed himself to be made the victim of a cruel swindle, but he had, as he suspected, rendered himself liable to be proceeded against by the inland Revenue authorities for offering "tea" without having a license. The story, however, leaked out, but he was never afterwards heard of dealing in goods he did not understand.—*American Grocer*, Aug. 7th.

EXCESSIVE PRODUCTION OF FRUIT.

The *Husbandman* says:—"There is no danger whatever that apples, peaches, pears or any other useful fruit will be produced in excess of the demand. The truth is, demand keeps pace with production. People will use a great deal more fruit when it is plentiful, and when they acquire the habit of using it they retain it.* There is, perhaps, no branch of farming that yields safer or more steady returns than orchard fruit."

ORANGES are now arriving from Australia in London in capital condition. Some of those I have seen are immense in size. Different methods are still being resorted to in the packing, some being packed in cork dust, and others only wrapped in tissue paper. Both methods, from recent experiments, seem to have met with considerable success. The flavour of the oranges is excellent, and compares most favourably with the flavour of any orange to be purchased in the streets of London.—*European Mail*, Aug. 30th.

BARLEY.—The result of the experimental cultivation of barley on the Nilgiris has proved disappointing. The out-turn per acre varying from 469 lb. in Todanad to 577 lb. In Merkanad, while the average yield per acre in good seasons was fixed as high as 1,500 to 2,200 lb. The experiment was inaugurated at the request of the Brewery Company, who would have been greatly benefited had it proved a success, as the Company would then have been able to manufacture their own malt instead of importing it at a high cost from Europe.—*M. Mail*.

FIGHTING THE FLUTED SCALE INSECTS.—Says the *Rural Californian*:—"The Australian lady bug, *Vedolia cardinalis*, is keeping up her reputation as a destroyer of the *icerya*. We have enough of the *vedolia*, if properly distributed, to soon have Mr. Cottony-Cushion Scale so reduced in numbers that he may no longer be considered a pest. What we want next is a parasite that will destroy the red and the San Jose scales: then we will be fixed. The Country Horticultural Commission have established a depot for the propagation and distribution of the *Vedolia*, on the Niles' place, on Washington street. They have five trees under tents all stocked, and will be easy to give away colonies by the 10th August.

* The very argument of Mr. Roberts as to Ceylon tea.—Ed.

A BIG TEA FACTORY IN HAPUTALE.—We hear that a big tea factory is now about to be erected on Laymas estate, Haputale, to serve the Dambetenne, Monarakande and Laymas estates. The factory will be the largest in the district, serving as it will a very large acreage indeed. It will be put up on the site of the old coffee store &c. bordering the Laymas road, and the tea from the upper estates will be sent down by a shoot. An order for all the iron work required has been sent home, and the district of Haputale will soon be able to boast of one of the largest factories in the island.

THE MARKING OF CEYLON TEA PACKAGES.—Much has been done in the direction of curtailment and improvement since we first wrote on this subject in November 1885, and we are glad to see Mr. Street in the *Overland Ceylon Observer* of July 22nd, pressing home our suggestions, which were to make marking as simple as possible. Mr. Street furnishes a specimen of marking in which the climax of simplicity is arrived at. Without wishing to be hypercritical we should prefer to see an invoice number or a "Break" number, rather than a chest number. Each chest on arrival is cut with a Dock number, which is afterwards put on the Weight Notes, Warrants, Delivery Orders, &c., and the chest number put on in Ceylon is useless as far as the Trade here is concerned. Mr. Street may be able to indicate some special reason for putting "Nett 50 lb." on the package. It may help in Australia where teas are often, if not always, sold by the package instead of by the lb. Here it is quite useless, and indeed as we have often pointed out gives unnecessary trouble in Ceylon, the Trade here being absolutely indifferent whether they pay for 47, 48, 49, or 51, 52, or 53 lb. in a "half-chest."—*J. A. Rucker & Benckraft's Weekly Tea Circular*, Aug. 29th.

THE TRADE OF INDIA IN HIDES, HORN, AND SKINS.—The magnitude of the Indian export trade in hides, horn, and skins is shown by some statistics on the subject which have lately been published. The official returns for 1888 give the exports last year at 570,843 cwt. of raw hides and 38,752 cwt. of skins, but these figures give a wholly inadequate idea of the slaughter which goes on year by year. Quite recently at the London Commercial Sale-rooms there were offered for sale in two days no fewer than 2,094,733 East Indian goat and sheep skins, 475,140 hides, a fair proportion of which were buffalo, and 325,453 horns, all freshly consigned. The sale in question was described as by no means a full one for Indian imports. Large as the figures are, however, the trade in Indian hides and horns was much larger. The exports of raw hides and skins in 1888 numbered roughly 10½ million pieces, as against 12½ in 1887, and there are signs of a further reduction in the current year. In five years the trade has absorbed the hides of over 40 million oxen, cows, horses, and buffaloes, to say nothing of the 21 million sheep and goats whose skins have been sent to various markets. With the decline in the hides and skin trade there has, singularly enough, been a marked increase in the export of horns, the 48,435 cwt. of 1887 having been increased in 1888 to 68,018 cwt., 1887, however, seems to have been a bad year in this branch of trade, for five years ago the exports of horns amounted to 59,300 cwt., and had fallen very little short of that in 1886. Of the two days' sale in London it is worthy of note that 200,253 of the horns put up were buffalo, 105,000 deer, and 200 ox and cow. There are no official statistics available as to description of horns, buffalo, deer, ox, and cow being all classed together, but it would seem that the number of Indian deer horns available for export has been steadily declining for some years past, the proportionate decrease over the figures of ten years ago being about 55 per cent.—*London Times*.

STEAM PLOUGH AT DEHRA.—In his paper on "The Mahratta plough" in the *Asiatic Quarterly* Sir George Birdwood made merry over the notion that team-ploughs could ever be introduced with success in India. A correspondent of the *Pioneer* writes from the Doon saying that steam-plough is a great success there, and is doing capital work, rolling over the jungle in fine style and rapidly clearing the lands.—*Indian Agriculturist*.

A MONSTER PIECE OF COAL.—A piece of coal, weighing 5 tons 10 cwt., has been cut at Abercane Colliery, to be sent to the Paris Exhibition as a specimen of the Welsh mining industry. It measures 7 feet 6 inches high, 5 feet 6 inches wide, and 3 feet 6 inches deep. It was hauled for a mile along the working to the pit's bottom, where it had to be trimmed before being raised. Five other blocks each 22nd tons, will accompany it.—*Indian Agriculturist*.

TANNING BY ELECTRICITY.—The process of tanning by electricity will be prominently brought before the public at the Paris Exhibition by French tanners and leather manufacturers, who have worked it successfully for nearly a year. By this process an establishment of moderate size, without costly machinery, will, it is said, be able to tan heavy hides in 96 hours, in place of the 12 months now required, and this at half the cost per pound of leather produced.—*Indian Agriculturist*.

THE OUCHTERLONY VALLEY.—In the Ouchterlony Valley, a correspondent writes to us, it has been raining incessantly without a gleam of sunshine for many days, and the abnormal fall of rain gaged from the 1st to the 15th September is 10½ inches. As coffee crops now require sunshine, it is apprehended that the heavy and continuous rain will affect the produce, which will otherwise promise a bumper crop this year. The public health in the Valley at present is not satisfactory, but the services of Dr. James Leach, the hardworking and painstaking Medical officer of the place, are much appreciated by the people.—*Madras Times*, Sept. 23rd.

QUININE PROSPECTS.—On this topic, the *American Drug Reporter* of Aug. 21st has the following deliverance:—

As to the probability of the improvement in quinine becoming permanent, or continuing for a considerable length of time, there are a number of contingencies to be considered, the effect of which may be to negative the proposition. As often pointed out in these columns the imports of quinine into this country have for the past four years at least, exceeded our consumptive requirements by an annual average of several hundred thousand ounces. This surplus, which is estimated at between seven hundred thousand and one million ounces is of course in existence, and unless it is controlled by strong hands, of which there is room for considerable doubt, it must continue to be more or less of a drag upon the market. There is also, according to the best authority, a large surplus stock in London and the Continental markets, which at any time may come out to stand in the way of an advance or cause reaction. As an offset to this it is asserted that all the bark imported into London during the last two years has been manufactured into quinine, and with constantly diminishing supplies at the source of production (Ceylon), even granting the existence of a heavy surplus of quinine it will soon be absorbed. Such arguments fail to consider Java bark as a factor of the situation, yet the product of the Dutch East Indies is already playing a most important part in determining the cost of quinine, and is apparently destined to become the leading feature of the situation in the near future. At present the Java product has an upward tendency, which seems to be based upon the improvement in the Ceylon bark, rather than upon any inherent strength of its own unless the reports we have seen of receipts at Amsterdam are erroneous.

"CUBEBS."—This valuable paper which is used in medicine, has hitherto been unattainable in Ceylon. Now however, we are glad to learn that plants have been taken kindly to the soil and climate of Peradeniya, and it is hoped that propagation from cuttings will be undertaken ere long.

GOLD IN WESTERN BORNEO.—Mr. E. L. Gordon has succeeded in obtaining from the Dutch Government leases for four gold concessions in Sambas, Western Borneo. Two of these are in favour of Mr. R. Liddelow and the other two in favour of Mr. Gordon. The area of the concessions covers in all about 160 square miles, and they have been tested and examined by experts sent from London for that purpose and with very gratifying results. The assays made by Johnson Mathey & Co. have shown a very high percentage in the quartz sent home. A company or companies will be floated in London by the Straits Prospecting Syndicate almost immediately to work the concessions.—*Indian Agriculturist*.

TRINIDAD is a sugar colony, but happily it has other staples which show a large increase in output, thus making up for the deficiency in the sugar crop. The export of sugar in 1888 amounted to £724,163, as against £800,595 in 1887. But the total exports in 1888 amounted to £2,132,761, as compared with £1,870,612 in 1887. The cocoa crop was an excellent one, the export being valued at \$611,876, as compared with \$354,420 in 1887. Among the other exports asphalt, bitters, coconuts, and molasses figure for considerable sums. The revenue, £480,523, is in excess of the previous year by £24,355, and of the expenditure by £17,000, though the latter was nearly £39,000 more than in 1887. Trinidad has a debt of £552,680. Coolie labour is largely used in Trinidad; 1860 immigrants having been introduced from India in 1888, while 435 returned, after serving their terms. It argues well for the treatment of these immigrants that many of them renew their contracts after their time has expired, while others return to settle in the colony after having gone home. A new steam service has been established round the island, touching at Tobago and direct into New York, in connexion with the fruit trade, which is a growing one. It is, moreover, hoped to extend the railway system, and so bring the capital and the seaboard into communication with the fertile districts of the interior. The resources of Trinidad are certainly capable of great development.—*London Times*.

SHAFT SINKING BY THE POETSCH FREEZING PROCESS.—It may be known by our readers that the application of freezing to the piercing of quicksands was suggested some time ago in America. Since then the Poetsch SooySmith Company has been carrying on operations according to this system, and the results have been very encouraging. The process commences by placing a series of verticle pipes in a circle around the space to be excavated. These pipes are closed at the bottom and a stream of cold brine is circulated through them. The result of this application is that the surrounding earth becomes frozen, and assumes the characteristics of a solid rock, so that the excavation may be conducted without the usual difficulties attendant on the sinking of a shaft through quicksands. The first successful boring conducted on this principle was at the Chapin Company's mines at Iron Mountain, Michigan, where the shaft was about 15 feet square by 100 feet deep. The Company are now making arrangements to open up the extensive anthracite beds at Wyoming Valley, Pennsylvania, which were unworkable on account of the superposed deposits of dangerous sands. It is confidently expected by the Poetsch Company that their system will enable a great number of mines to be worked in perfect safety which have hitherto been inaccessible.—*Industries*.

TEA WITHERING AND TEMPERATURE.

The remarks made by Mr. John Hughes, the well-known Agricultural Analyst, to our London Correspondent, and reported by the latter in his latest letter, are certainly worthy of careful consideration. It seems to be the opinion of many of the home experts in tea that the irregular quality of much of the outturn of our staple must be held to be due to some defect in the primary operation of withering the leaf. Whether the imperfection asserted as to our local methods in this particular can confidently be attributed to the cause to which Mr. Hughes has assigned it, will no doubt form the subject of considerable controversy; but Mr. Hughes is so capable an authority on many matters connected with agriculture, that it would certainly be unwise to pass his remarks on this subject lightly by.

That gentleman has stated his experience with regard to three of our local factories visited by him. In one of these he found the temperature of the room in which withering was proceeding to be 85 degrees Fahrenheit; in a second it was but 73 degrees; and in the third instance he was unable to ascertain it owing to the fact that the establishment was wholly unprovided with the necessary instrument for doing so. The last of these instances is certainly a very extraordinary one, or we believe that it will generally be conceded that the temperature in which all the several operations of tea preparation are carried on is an important element towards their success. Indeed, we should say that when that element is entirely neglected—as it appears certain it must have been in this particular case—no decided results could with confidence be anticipated; and if we thought that such a “happy-go-lucky” procedure was common among us, we should not have far to seek for the causes upon which the complaints occasionally reaching us from home as to irregularity in the quality of Ceylon teas are founded. But we must refuse to consider this as anything but an isolated and extreme case. The question of temperature, we are sure, is not neglected by the mass of our tea planters, and we are equally sure they would be glad of any intelligent suggestions which would enable them to give fuller effect to their desire to so regulate the heat of their withering-rooms as to produce the best results. In the preparation of their teas, the planters of India and Ceylon have taken what is a new departure from the crude practices of ages of procedure in China. They have endeavoured by scientific methods to attain the results which centuries of practice have enabled the cultivators of China to achieve by the most simple manual methods. To make machinery imitate the intelligence and careful manipulation of man, necessarily involves long experience which is sure to be attended during its progress with many mistakes and shortcomings.

Now to this matter of the withering of tea the peasant of China devotes his personal and most careful attention. He sits over his trays either in warm sunshine or in the almost unvarying temperature of his hut, and shifts the leaf constantly by hand as the conditions observable by him vary. We have to endeavor to imitate that care and watchfulness on so large a scale as precludes the same close personal observation. How then can this be successfully accomplished? Our tea factories are mostly situated in localities exposed to constant changes of temperature and climatic conditions generally. They are largely built in such a manner as to be open to the effects of the external temperature, and if the operation of withering is

to be successfully conducted, these adverse conditions must be combated. In order to do this, it must first be necessary to make provision for the exclusion of free currents of air, charged as these constantly must be with the damp so commonly experienced in our hill-country. This may be readily done by having the venetians, with which so many of our factories are endowed, capable of being shut or opened to any desired degree. If that be done, the question of raising the heat in our drying rooms is one which need never prove difficult of solution. Heat to any required degree can always be made available. It is far more difficult, on the many sultry days experienced, to reduce the temperature below that of the external air. But motive power of one kind and another is always available on our estates, and it might be employed to effect the required reduction in temperature when the absence of motion in the external air prevents this passing during its entry through wetted cloths or tats.

It has been suggested to us that a fan, worked by the power we have stated to be always at hand, should draw air through a box chamber in which cloths kept constantly damped should be hung. We all commonly know how very great is the cooling effect of such a process, and the air so drawn and passed into the withering-rooms would soon bring down to the desired figure the registration of the thermometer within them. It may perhaps be correctly thought that air so obtained would be charged unduly with moisture and so prove detrimental to the dry withering desired, but we are assured that, if the air, before leaving the discharge pipe from the fan, is passed through a loose packing of cotton wool or other closely fibrous material, it would give up all trace of dampness in its passage through it, and frequent changing of this would insure perfectly dry, cold air entering the withering-room. Of course, it has first to be determined what should be the standard of temperature best calculated to ensure good results. We have no doubt, however, that experience can already dictate this, and we believe that some endeavour in the direction we have pointed out to maintain the air at the perfectly uniform level of a standard so fixed would prove to be productive of good results. Certainly the view taken by Mr. Hughes appears to be founded on commonsense, and it will be a pity if, in their own interests, our planters do not make the endeavour to act upon it.

CEYLON UPCOUNTRY PLANTING REPORT.

UPCOUNTRY RAINS AND THE DIFFICULTIES PLANTERS HAVE TO CONTEND WITH—THE HIGH PRICE OF RICE AND COOLIE WEDDINGS—COFFEE CROPS AND COFFEE-STEALING—TEA—CA CAO.

Sept. 19th, 1889.

The present weather really demands the first notice: more outrageous for September could hardly be conceived, and the sodden condition of the ground pretty well represents our mental state; anything that offers itself is seized on as a source of excitement in this dreary dead level of daily drip. A bushel of *ficus* seed arrives at a neighbour's, and he gets properly jubilant over it; sees in the near future a bright career opening for our Old King, and tries to forget the wretched weather, in the contemplation of a revival of coffee. This gleam of hope has the same kind of mental effect as sunshine, but it is a sorry substitute for it. At the morning muster you consider that you are a special favourite of Providence, if you have “a dry blink” during parade, but if a smart shower sweeps

down on you, your coolies are stirred into a mild kind of mutiny and try the effects of sarcasm on your sense of duty. As the wind and wet make themselves disagreeably felt, on yourself and your labourers, the sneaking inclination to return under cover is apt to be unlawfully strengthened by the murmurings of those around. "Are we men or cattle that we should have to work in this rain?" is the indignant question commonly asked from behind a cumbly; and when you try to ignore the query, and look as if you regarded it as an impertinence offered to the dignity of authority, someone else has a protest to add, addressed as it were to the world at large. This morning at muster when the rain was coming down thick and fast and the damp mist whirling about, a voice said, as if there had been a public debate on for some time: "Why you can't even see the town, and he expects us to be able to see the flush!" We will be all glad of a change of weather, just to get things to work sweetly. As it is at present the wet offers all kinds of obstacles, and hitches are constant. Your bungalow doors in a way represent how things are; some of them will hardly work at all, and even the best show a tendency to swell, and give trouble.

The high price of rice which has of late obtained affects the coolies in various ways. One of my fellows who got leave to go away for a week to arrange for his marriage tells me he won't go now, until the price of rice has fallen. There is not much of the ardent lover there. It is however rather curious to note here in the East, the same tendency as has been marked in the West. The price of wheat there has its effects on marriages, as the price of rice evidently has here.

COFFEE is beginning to ripen up a little here, and this wet weather should help somewhat to mitigate the effects of the leaf-disease on the out-turn of light. But after all it is precious little of the Old King that is about, although we would all like to see more.

In the villages the little coffee that remains is a sad temptation to the needy. To be out coffee stealing, even although all the spoil that can be got won't amount to more than half a cooty-sack of green, has the same effect on the old Sinhalese estate marauder as a sea-song has on an ancient mariner. How it wakes him up, giving birth as it were to energy, point to his purposeless life, and an object to his thriftlessness. And when he gets caught, and appears at Court, as he is beginning to do now, you wonder why he should have risked his liberty for the few handfuls of green rubbish, which tied up in the corner of a dirty cloth are evidence against him. Not that he stole all that is brought in—more than likely not the half of it, for it is wonderful how the Sinhalese will help his brother—to a conviction—when the opportunity offers—and add, even though it be at his own cost, to the weight of evidence.

TEA is flushing here, all things considered, in a fair kind of way, but we sadly want some more sun. A real hot day would be a godsend.

The borer in the CACAO still gives a lot of trouble. Perhaps this damp season has been more than usually favourable to their propagation, for hunt as you may they seem hard to exterminate, and the tale of the slain rises in a moderate acreage to many thousands every round. All the same the cacao crop is very promising, but how much may turn out damaged through this wretched plague, will be known later.

PEPPERCORN.

THE CINCHONA SYNDICATE.

The "Circular" appended will show to all interested the outcome of the recent correspondence in the columns of the *Observer* and *Tropical*

Agriculturist, and of the discussion which followed. We think whatever be the result of the present appeal, that all holders of cinchona bark should feel indebted to the gentlemen who have come forward with a practical proposal to meet an admittedly unsatisfactory and we would almost say, unjustifiable state of affairs. Ceylon Cinchona planters cannot fail to have confidence in Messrs. Bois, Mitchell and Grinlinton as reliable men of business and of standing equal to the amplest guarantee that they will carry out what they propose, if they but get sufficient support. We have previously stated that this sufficiency might be found in the adherence and support of all who still own the equivalent of 25 acres and upwards of cinchona. The owners of smaller areas might, we think, be left out of consideration, and seeing how largely Ceylon still governs the bark market, an Association of such owners as we refer to, could not fail to be of much importance. At this moment he would be a bold man who would venture to say that Ceylon is not to send 8 million lb. of bark away next season. We are aware that estimates are as low as 6 millions, but who in Europe will believe them in view of past experience. On the other hand, through the existence of a controlling Syndicate if it were made clear that not more than 5 to 6 million lb. would be shipped, it is very certain that the aggregate return for this quantity would be in excess of the price likely to be paid for the larger shipments of 8 million lb. The circular has been sent to all interested and the promoters think that with reasonable support the scheme should succeed; for if a stop can be put to the time bargaining in quinine, and the "bearing" of the cinchona market by quinine manufacturers, the Syndicate would largely reinstate the bark market in its proper position.

(Circular.)

Colombo, Sept. 20th.

Dear Sir,—It is contemplated to form the "Ceylon Cinchona Syndicate," for the purpose of receiving, pressing and storing Cinchona in Colombo, until shipment, and the undersigned will be glad to know whether in the event of the Syndicate being fully constituted, you would be willing to give it your support by sending your Cinchona to it.

The terms upon which business would be done are as follows:—

Advances would be made to growers, of 50 per cent of Colombo values on ascertained analyses. It would be stored free of rent for 4 months, after which a moderate rent would be charged till time of shipment.

Interest would be charged at 8 per cent per annum. Pressing charges including shipping would be 2c. per lb.

Shipments would be made in the same rotation as that in which the Cinchona was received, but only at such times as the Syndicate might deem to be desirable.

Owners of Cinchona might have shipment when made, consigned to their order, in which case advances would have to be repaid at the time of shipment, but if the sale of the Cinchona in London were left in the hands of the Syndicate, the advances need not be repaid until proceeds are accounted for. Arrangements could also be made for the holding of Cinchona longer than the time at which, in rotation, its turn would come round for shipment.

Your reply at your earliest convenience will much oblige.—Yours faithfully,
 FRED. WM. BOIS,
 W. W. MITCHELL,
 J. J. GRINLINTON.

TOBACCO IN DELI.

The *Delhi Courant* of the 31st August states that during the month the tobacco crop had been cut on most of the estates. Owing to the heavy rains in the previous three months, the yield will be much smaller than had been hoped and expected at first.

Deli, so far has nothing to fear from competitors in the tobacco growing line. Her rivals under that head still lag behind. The Germans tried their best to grow the leaf in East Africa and Zanzibar, with at first highly flattering prospects. An experienced planter was got out from Deli to manage the estates, and at the outset, the results looked promising enough. The outcome, for all that, has been thoroughly disappointing. The Deli planter has returned to Europe, and the shareholders in the Company under his management have lost their money. The main cause of the failure lay in the scarcity of labour. People in Europe cannot understand that the fact of a man being coloured does not qualify him to be a tobacco labourer. They do not take sufficient account of the circumstance that the success of tobacco cultivation in Deli depends upon Chinese coolies. That African negroes fail to come up to their needs excite no wonder except among ignorant shareholders.

Last month the "China" arrived at Belaman with 82 free coolies from the Celestial Empire. The number is considered satisfactory, owing to the paddy season in China interfering with emigration.

The district of Bila begins to draw attention for tobacco growing. Not only has a Dutch Company taken up land for the purpose, but the firm of Plumacher and Rohrig also. Previous pioneers there had met with only disappointment.—*Straits Times*, Sept. 9th.

FINE SALE OF CANNAVERELLA CINCHONA BARK.

Mr. E. John sold a very fine parcel of "Cannaverella" bark yesterday, about 23,000 lb. renewed shavings (analysis 5.25) at 10 cents per unit—52½ cents per lb. This is very good indeed.

CINCHONA IN CEYLON.

Mr. Wijnschenk-Dom has just returned after a trip of some 17 days' duration through our Cinchona districts: he has visited the Agras, Udapussellawa, Badulla and Madulsima districts, and he has returned quite satisfied that Java has very little to fear from the competition of Ceylon in the early future. Four or five years, he thinks, will see our exports of cinchona bark dwindle away to an unappreciable quantity. Our visitor, in fact, saw no expanse of cinchona cultivation worthy of special note save on Cannaverella estate. That, he maintains, is the finest cinchona plantation in Ceylon: it is worth coming from Java to see it; and Mr. Macfarlane he found to be an enlightened and enthusiastic cultivator, very much after the fashion of the Java planters who give all their thoughts to cinchona. Mr. W.-Dom was everywhere most kindly received, but most of the other gentlemen, as he says truly, had tea and coffee more in view perhaps than cinchona. He thinks that Cannaverella might well be the Ceylon show-place with reference to cinchona, and then we have to realize that there are perhaps 25,000 to 30,000 acres similarly cultivated in Java, and a good deal with ledgerianas of which there are few in Ceylon. All this may be true, but we suspect it will be found that the Uva districts with a more encouraging market can go on permanently, giving two or three million lb. of good marketable bark, even after our total export dwindles to a half or third of what it now is. Our visitor after seeing our districts does not think it is necessary to form a Syndicate in Java.

CHEAP TEAS.—A correspondent, in sending us the following advertisement out from a home paper, says:—"Here is the secret of the very cheap tea: Advt. Lodging-house keepers and others—used tea leaves bought any quantity, at 5s per cwt. Apply No. 559, Advertiser Office."

TEA IN JOHORE.—The other day Mr. Mackenzie, of Michaelstowe Estate, Johore, sent us a packet of Pekoe tea grown there, and of which the retail price in the Straits is a dollar a pound. The tea has since been tried, and it is very good. It is a better class of tea than can readily be got retail in England, for, oddly enough, the best teas sent to London are not consumed there, but are sent to Ireland, where they are bought by a virtuous and starving peasantry.—*Straits Times*, Sept. 17th.

COFFEE.—A Perak correspondent writes:—Coffee, Arabia and Liberia, are both doing exceedingly well in this locality; all that is wanted to make the planting of the fragrant bean a success being cheap free labour, and that lies in the hands of the Government. At present exorbitant rates are paid for public works by Government officers and contractors, while the unfortunate planter is compelled to pay an equivalent, if he wishes to have his work done, or else import coolies from India, at much expense, to find that at the end of the 2nd or 3rd month the best of his men have gone to Government works, where they can double their wages and free themselves from their liabilities. [We think our correspondent exaggerates a little. Contract labourers cannot leave till their contract has expired; although of course a few may run away and trust to avoid recapture.]—*Straits Times*, Sept. 17th.

JOHORE TEA.—We are glad to learn that Johore tea is being pushed to the front. Mr. Turing Mackenzie, of the Michaelstowe plantation, who has lately arrived from Ceylon is about to send samples of his teas to the Argentine Republic International Agricultural Exhibition which is to be opened in April, 1890. It is only by steps such as these that any new growth can push its way into new markets and make its merits known. There is no reason why Straits planters should be behind their active fellow planters in Ceylon. No chance is lost by Ceylon planters and their vigorous Association to thrust their way into every field and Ceylon tea everywhere, at home, the continent in America, and the Colonies is being well advertised. The proposed Straits Planters Association should not neglect the claims of tea but should take every chance of making the local product better known, and thus increase the demand. We have this day received a sample pound packet of Johore tea price one dollar and shall make a point to submitting its contents to critical palates for approval.—*S. F. Press*, Sept. 11th.

COFFEE IN THE WYNAAD is beginning to look up. We hear of one gentleman largely interested in the cultivation and a most successful planter, starting a fresh clearing of some six or seven hundred acres in the neighbourhood of Nellacottah. It is a common practice for tyros, to open fresh land as soon as the market goes up, forgetful of the fact, the five or six years must elapse before the new clearing will make a return and that present prices may not be maintained till then, but when an old hand well accustomed to the fluctuations of the market does the same thing, we may rest assured that faith in coffee is unshaken. It is very satisfactory to note this indication of a returning faith in our most popular product which has contended against great difficulties natural and artificial. Bug, borer and leaf disease have united their forces to extinguish the cultivation but without success. Low prices and high charges, combined with the difficulty of obtaining money for working have done their worst, but with no better result. Coffee still is king and there are not a few who believe it will continue to be so.—*South of India Observer*, Sept. 14th.

BLACK WATTLE BARK AND OTHER TAN BARKS.

On this subject we have received the following interesting letter:—

To the Editor "Ceylon Observer."

The Technological Museum, Sydney,
August 3rd, 1889.

DEAR SIR,—With reference to the correspondence on the subject in the July issue of the *Tropical Agriculturist*, I beg to give you the following information, having made a speciality of Australian tan-barks during the last few years.

In the first place, a word as to botanical and local nomenclature:—*Acacia decurrens* Willd. is the principal species called "Black Wattle"; it also goes by the name of "Green Wattle." The variety *mollis* (not *mollissima*), has been properly restored to specific rank, and is now as formerly *A. mollissima* Willd. Its commonest names are "Black" and "Silver Wattle."

With reference to memo. by "J. D. V." the timber of neither species is thought much of here; it is occasionally used for staves and only occasionally for fuel, eucalyptus timber being our great wood-fuel. In Australia the wood of acacias is exceedingly liable to attacks by the larvæ of certain lepidoptera,* and often for miles it is difficult to get a sound log.

In regard to Mr. Tringham's letter, 34'35 per cent tannic acid is excellent, and the 40 per cent quoted lower down and also 47 per cent for *A. pycnantha* probably refer to extractive, and not to tannic acid. I challenge any man to produce a sample of either bark, which will give such results with a standard process such as Löwenthal's. There is frequently much quackery in so-called tan-analyses, and some flagrant instances of bogus analyses have come under my notice at the Museum. The analyses in the report of the Victorian Wattle Bark Commission, from which all the information on the subject in Spon is derived, refer only to extracts and not to tannic acid, a distinction with a very important difference.

Ere this letter reaches you, you will have received through Messrs. Trübner & Co. a copy of my "Useful Native Plants of Australia," which gives the fullest information upon our tan-barks yet published. All the analyses there given are of barks from trees botanically determined for the purpose. Since the work was published I have read part V. of "Some New South Wales Tan Substances" before the Royal Society of New South Wales (a copy of which I beg to send you), and there record the percentage of tannic acid in *A. decurrens* bark at 36·297 per cent, the highest I have ever come across in all my experience.

Mr. Tringham mentions that from *A. decurrens* he gets a soluble office gum. This is not our experience in Australia, as the gum of *A. decurrens* is all but insoluble in water, simply forming a jelly in that liquid. I send a specimen of botanically correct Australian *A. decurrens* gum to illustrate my remarks.† If Mr. Tringham is not mistaken in his species, the occurrence of a soluble gum on this species in Ceylon is most remarkable; and if he has any doubt, I hope he

will submit flowering and fruiting specimens to some competent botanist.*—Yours faithfully,
J. H. MAIDEN, Curator and Secretary.

Mr. Maiden is correct in supposing that, in addition to a series of valuable papers on objects in the Museum of which he is the very efficient Curator, sent to us from Sydney, we have received from the London publishers a copy of his interesting work on the Useful Native Plants of Australia, which we value very highly and to which we shall frequently have to make reference as the qualities and products of Australian trees are discussed, whether as yielders of timber, or foods, drugs, oils, gums, dyes, tans, fibres, &c. We strongly recommend this book, published by Trübner & Co., to readers interested in the culture of Australian trees. At present, we turn to the information contained in the pamphlet forwarded with Mr. Maiden's letter, and we find the following details:—Löwenthal's process of analyses of tanning substances is fully described, and various tanning barks are noticed. First comes that of

Cupania semiglauca, F. v. M., N. O. Sapindacæ, B. Fl., i., 457.

Of this bark Mr. Maiden writes:—

Externally this bark might perhaps be mistaken by an expert for Black Wattle bark (*A. decurrens*). Certainly it would require more than a casual observation to detect its substitution if admixed with Wattle bark in the bundles as ordinarily sent to market.

But there are important differences, the characteristics of the bark of *A. decurrens* being thus stated:—

1. May be considered perfectly smooth.
2. Slight longitudinal flutes on the outside.
3. The inside is usually nearly as smooth as dressed timber.
4. Inside bark dark reddish brown.

The results of analyses of the bark which resembles that of *A. decurrens* so closely are thus given:—

Extract.—28·62 per cent. Colour, rich orange brown slightly darker than that of *Callicoma serratifolia*; of moist residue, ochrey brown.

Tannic acid.—14·933 per cent. *Non-tannin and impurities*—9·14 per cent.

Passing over a couple of acacias we come to *A. salicina*, which gave

Extract.—35·28 per cent. Colour, bright ruby; of moist residue, dark pure brown.

Tannic acid.—13·206 per cent. (The blacks are aware of the value of this tan-bark, as they use it for tanning wallaby and other skins.) *Non-tannin and impurities*—1·524 per cent.

Next we have *A. prominens* with extract 39·98 per cent and tannic acid 14·425. *A. elata* gave 36·2 p. c. extract and 20·11 tannic acid. And now come the extraordinary results obtained from *A. decurrens* bark, from a high table-land:—

Extract.—62·54 per cent. Colour, rich ruby; of moist residue, very dark sienna-brown.

Tannic acid.—36·297 per cent. *Non-tannin and impurities*—2·438 per cent. The percentage of tannic acid is extraordinary, and in order to avoid all possible error, the above is the mean of three separate analyses (not of three samples of the same liquor but of three separate liquors), which gave closely agreeing results.

Mr. Thomas Shepherd, an enterprising tanner of Cambewarra, N. S. W., has kindly furnished me with

* We hope that Mr. Tringham will act on this hint; and if Mr. Maiden would kindly make up specimens of *A. decurrens*, *A. pycnantha* and *A. dealbata* and send them to us by an officer of one of the P. & O. steamers, we shall feel much obliged, and we may thus be able to settle doubt as to the identity of some of the acacias naturalized in Ceylon. Some seeds of *A. binervata* would also be welcome, and we should gladly remit the cost.—Ed.

* We have not observed any such tendency in Ceylon and of course our correspondent did not mean to include that source of fine timber, *A. melanoxylon*,—the "blackwood" of Australia.—Ed.

† Not received.—Ed.

the following information in sending this sample. Of all New South Wales localities, he prefers Nerriga for *A. decurrens* bark. He says it would be quite equal to Tasmanian if it could be obtained as finely ground. From the Cambewarra bark already described (xxi, 33), Mr. Shepherd obtains only two liquors, of which the second is very weak, while from the Nerriga bark he invariably obtains three strong liquors. In his opinion, the best time for stripping is when the trees are in bud, and have just come into flower. Next to the Nerriga bark he speaks highest of that coming from the Bega district. Nerriga is on the high table land, on the road from Nowra to Braidwood. What is stated of quality of Tasmanian bark of *A. decurrens* reminds us that we found this wattle as the undergrowth of peppermint gum forests on hills rising above the banks of the Derwent, in the Southern colony, most of the trees being stripped of their bark for export, which was going on briskly. The trees were invariably stripped standing, and we could not help thinking that in the case of some of the most valuable kinds it might pay to shave or bark partially, à la cinchona bark. The bark of *C. succirubra*, by the way, was found by Mr. H. Humphreys, the Dimbula planter, who had had experience in tanning processes, to be rich in tannic acid, and we were interested to find in Mr. Maiden's volume that the bark of *Cedrela toona* (one of the finest of timber trees) yields an appreciable amount of tannic acid. Another sample of bark of *A. decurrens*, although considered by a tanning authority to be very superior, gave less favourable results, extract 53.96 p. c. and tannic acid 24.99. Then come remarks which are worth quoting:—

In regard to this second sample of *A. decurrens* bark Mr. Shepherd informed me that not a drop of rain had fallen on it since the day it was stripped. It is sent as "an exceptionally good sample." This bark is "exceptionally good" as regards lightness of colour of extract, and consequently would produce very lightly coloured leather, as also tested by me with hide powder but it is not of the highest class in richness of tannin, as Mr. Shepherd would realize when he came to use it. The present is a good illustration of the danger of trusting to appearances with wattle bark. In Europe and America analyses of tan materials are usually made in the laboratory of the tannery itself. Mr. Shepherd states that *A. decurrens* gives a denser liquor than *A. binervata*, sometimes so dense that he has some difficulty in making his hides sink in it. He also points out that the tannin of *A. binervata* is more quickly extracted by water than that of *A. decurrens*, and that the liquor obtained is quicker and sharper in its action than that from *A. decurrens*; he finds *A. decurrens* better adapted for heavy leather such as sole and mill-belt, but not so well for lighter work,—uppers, &c. for which he prefers *A. binervata*.

A. binervata, thus alluded to, gave extract 37.8 p. c. and tannic acid 19.301. Remarks follow to this effect:—

Mr. Shepherd states that many years ago he was employed in a tan-yard in which "Ironbark" (*Eucalyptus siderophloia* or *E. leucocylon*) was used for tan-bark. The process of tanning went on satisfactorily, but in the end the leather assumed a "bloom," which did not take the market, although he believes the leather itself was not inferior in quality. He also remarks that working with *Eucalyptus* bark had the advantage over *Acacia* bark in that when hides were tanned too hard, part of the tannin could be removed and the hides rendered softer; *A. binervata* bark permits this to a slight degree, but not *A. decurrens*.

Although in these papers I have not touched upon the "liming process," nor upon any of the tanning processes, the following note is interesting:—Mr. Shepherd's experience with lime is that he can always depend upon shell-lime to obtain uniform results, whereas he cannot depend upon stone-lime, as by the use of the latter article the hides sometimes come out a dirty brown or rusty colour.

Going off from both *acacias* and *eucalypti* we find that

Ceratop. talum Apetalum, *D. Don.* N. O. Saxifrageæ B. Fl. ii., 442, gave extract 34.14 p. c. and tannic acid 20.52. The *Eugénias* (which include the jambu) being common in the forests of Ceylon, it is interesting to learn that the bark of an old *Eugenia* tree yielded extract 52.88 p. c. and tannic acid 28.648. Mr. Maiden remarks on this:—

An extraordinary result (the mean of three distinct analyses), and inasmuch as the colour of the extract both alone and with hide-powder is not objectionable, this appears to be a valuable addition to the raw vegetable products of New South Wales. A tanner has undertaken to tan a sample of hide with this bark (which is by no means rare), and I will submit the leather to the Society in due course. This sample is from the bank of the river; I will endeavour to ascertain whether bark from a tree of the same size in the adjacent mountains contains a different percentage of tannic acid.

Then

Hakea Saligna, *R. Br.*, N. O. Proteaceæ, B. Fl., v. 512,

gave extract 36.96 p. c. and tannic acid 20.42. Then come the *Casuarina* barks, that of *C. suberosa*, gave extract 24.6 p. c. and tannic acid 13.511. *C. torulosa*, a beautifully tall, slender and straight tree with "weeping" branches and corky looking bark, gave extract 10.78 p. c. and tannic acid 5.384. It is evident that this graceful variety of *casuarina* is valuable not so much for tanning bark, as for its ornamental appearance and its timber specially valuable as fuel, but valuable also for shingles and cabinet work. As the "drooping she-oak," Mr. Maiden thus describes the tree:—

The appearance of this bark is characteristic. The furrowing is deep, and is divided transversely. In flaky barks the flakes are of course attached by their flat sides to the tree, but in this instance, each flake (roughly about an inch by one and a half inch and a quarter of an inch thick) is set on end with great regularity, and each may be detached without removing its neighbour. Each flake is corky. Inner bark very coarsely lenticular. Average thickness of inner bark $\frac{1}{4}$ inch, of outer bark (flakes) 1 inch. Colour of dry powder ochrey-brown.

The flakes of the outer bark are so readily separated that the author considered it useful to make separate determinations of the inner and outer barks. *Outer-bark*—Yields extract to water 3.08 per cent. Colour of dry powder, ground coffee, which it much resembles; colour of extract, sherry; of moist residue, Vandyke brown. Tannic acid 1.524 per cent. Non-tannin and impurities, .609 per cent. *Inner bark*—Extract to water 31.38 per cent. Colour of dry powder reddish-buff; of extract, orange-brown inclining to light ruby; of moist residue, raw sienna inclining to brown. Tannic acid, 12.495 per cent. Non-tannin and impurities, 1.117 per cent. From this it will be seen that the inner bark is rich in tannic acid. These trees are only used for fuel, for which they are excellent, and it does seem a waste to allow so much tan-material to go unused. Although in the above extract from his pamphlet Mr. Maiden mentions *C. torulosa* as used chiefly for firewood in its native habitat, yet his own account of it in his *magnus opus* proves that it has many and valuable properties beside being the best oven fuel. As a fuel tree it can, from our observation of it on Abbotsford, be grown a greater number to an acre than most other trees, from its tendency to shoot up out of all proportion to its increase in circumference while its branches hang down instead of standing out horizontally. Mr. Maiden's account of it as a timber tree is as follows:—

Casuarina Torulosa, *Ait.*, (Syn. *C. tenuissima*, Sieb.); N. O., Casuarineæ, B. Fl., vi., 200
"Forest-oak." "River-oak." Called "Mountain-oak" in Queensland. "Beef-wood." The "Noa-

loi" of the aboriginals of Northern New South Wales' and the "Koondeeba" of those of Southern Queensland "Bureutha" of some Queensland aboriginals.

Much used for fuel. The wood is close, and prettily marked, yielding handsome veneers. This handsome wood has a marking peculiarly its own. The line of demarcation of the heart-wood is well-defined. It is used for cabinet-work, and produces very superior shingles. It is one of the best woods for oven fuel. A slab in the Technological Museum, which has been seasoned over twenty-five years (having been exhibited at the London International Exhibition of 1862, as *C. tenuissima*), has a weight which corresponds to 64 lb. per cubic foot. Diameter, 18 to 24 in.; height 60 to 80 ft.

New South Wales and Queensland.

Let us now see what Mr. Maiden says in the tan bark section of his valuable book on the native plants of Australia, of the three leading acacias which in addition to *A. decurrens* have been naturalized in the hill-country of Ceylon viz.: *A. pycnantha*, *A. dealbata* and *A. melanoxylon*. Of *A. pycnantha* (what we know in Ceylon as "the golden wattle," from its beautiful and fragrant yellow blossom,) Mr. Maiden writes that it is second, perhaps, only to *A. decurrens* in importance for its yield of tanners' bark, the bark although less in quantity being sometimes better in quality. It has yielded as high as 55.3 per cent of extractive matter and 34 of tannin, and even the dried leaves have yielded 15.16 per cent of tannic acid. While *pycnantha* is described as yielding one of the richest tanning barks in the world, *A. dealbata* is referred to as "an excellent tanning material, although the bark is thinner and inferior to that of *A. decurrens*, var. *mollissima*." A specimen in the technological museum at Sydney contains 29.25 per cent of tannin, and Mr. Maiden's analysis resulted in 29.86 per cent of extract and 21.22 per cent of catechu-tannic acid. The bark is chiefly employed to tan lighter leather. *A. melanoxylon* is valuable mainly for its excellent timber, beside which it is a highly ornamental tree, but the bark might pay to collect and send to market when the trees are cut for timber or pruned for fuel, for it yielded to Mr. Maiden's analysis 20.63 per cent of extract and 11.12 per cent of catechu-tannic acid. Many of the eucalypts and other trees are rich in tannin, but if cultivation with reference to marketing the bark is contemplated, it seems pretty clear that special attention should be devoted to the two wattles which flourish so freely in and around Nuwara Eliya: *A. pycnantha* as yielding a bark useful for light leather, and *A. decurrens*, var. *mollissima*, for heavy leather. The cultivation of *A. binervata*, if we have it not already, ought to be added. The export may be in the shape of bales of dried bark; boxes or barrels of ground bark, or the extract (including that of leaves and twigs) in casks or jars. The trees are represented as mature in Australia in the tenth year, but in our forcing climate maturity would probably be attained in a shorter period, and thinnings can be utilized, for bark or extract and as firewood, from the third year. Baron von Mueller in his work on *Select Extra-tropical Plants* gives the following details regarding *A. decurrens*, var. *mollissima*, the richest yielder of tanning bark, by far, of all the "Wattles":—

"The bark, rich in tannin, renders this tree highly important. The English price of the bark range generally from £8 to £11. In Melbourne it averages about £5 per ton. It varies, so far as my experiments have shown, in its tannin, from 30 to 54 per cent (*sec*) in bark artificially dried. In commercial bark the percentage is somewhat less, according to the state of its dryness—it retains about 10 per cent of moisture. 1½ lb. of Black Wattle Bark gives 1 lb. of leather, whereas 5 lb. of English oak bark are

requisite for the same results; but the tanning principle of both is not absolutely identical. Melbourne tanners consider a ton of Black Wattle Bark sufficient to tan 25 to 30 hides; it is best adapted for sole leather, and other so-called heavy goods. The leather is fully as durable as that tanned with oak bark, and nearly as good in colour. Bark carefully stored for a season improves in tanning power 10 to 15 per cent. From experiments made it appears that no appreciable difference exists in the percentage of tannin in Wattle Barks, whether obtained in the dry or in the wet season. As far back as 1823 a fluid extract of Wattle Bark was shipped to London, fetching then the extraordinary price of £50 per ton, one ton of bark yielding 4 cwt. of extract of tar consistency (Simmonds), thus saving much freight and cartage. The cultivation of the Black Wattle is extremely easy, being effected by sowing, either broadcast or in rows. Seed can be obtained in Sydney or Melbourne, at 5s per lb., which quantity contains from 30,000 to 50,000 seeds; they are known to retain their vitality for several years. Seeds should be soaked in warm water before sowing. Any bare, barren, unutilised place might be most remuneratively sown with this Wattle; the return would be in from 5 to 10 years. Full-grown trees, which supply also the best quality, yield as much as 1 cwt. of bark. Mr. Dickinson states that he has seen 10 cwt. of bark obtained from a single tree of gigantic dimensions at Southport, Queensland. A quarter of a ton of bark was obtained from one tree at Tambo, Queensland, without stripping all the limbs. The height of this tree was six feet, and the stem two feet in diameter. The rate of growth is about one inch in diameter of stem annually. It is content with the poorest and driest, or sandy soils, although in more fertile ground its growth is more rapid."

We do not know that at the prices quoted it would pay to grow the acacias mentioned merely, for the sake of the bark, but, as yielding firewood and small timber in addition, acacia groves ought to be profitable.

COTTON CULTIVATION IN INDIA.

Dr. Wight in his exhaustive work on the Botany of India, published in Madras in 1840, devotes a few pages to the subject of cotton and cotton-growing in India. His classification of the different varieties, as well as his conclusions, drawn from experiments, as to the adaptability of certain varieties for the climate and soils of India, will not be without some interest and usefulness to cotton growers in Ceylon. Dr. Wight acknowledges three species:—(1) *Gossypium herbaceum*, with palmately lobed leaves, whether annual or perennial; (2) *G. barbadense*, the American variety, with simply lobed or angled leaves, leaving duration out of the question; (3) *G. acuminatum*, comprehending Pernambuco, Peruvian, Bahia, Ava. The last name is advisedly chosen as expressing the prevailing form of the lobes of the leaves rather than the native country of a plant so widely distributed. Among the many varieties under the first are *G. arboreum* and *G. religiosum*. The *G. herbaceum*, says Dr. Wight, need not be dilated on, since, as the indigenous species, it is so well-known in India and over all the warmer portions of the old world: it being the first and best known, species to mankind generally.

G. barbadense is one of the oldest species of the genus, having been established by Linnæus on the authority of a figure of Plucknet, published 1691. It was, says Swartz, most extensively cultivated in the West Indies, and thence accordingly to Roxburgh, brought to the islands of Bourbon and Mauritius, whence again it was introduced to India under the name of Bourbon. Its deterioration in the West Indies, Bourbon and Mauritius, and consequent discontinuance, are attributed to a neglect to renew the stock by the use of fresh seed, and to exhaustion of the soil owing to continual growth of the crop for a long time. In Spain, Malta and Sicily, where attention was paid to these points, the growth was most successful

Other two varieties of *G. barbadense* are "Sea Island" and "Upland"—the former long and the latter short stapled. The peculiar and very superior qualities of the Sea Island are attributed to its growing in a soil highly calcareous and highly impregnated with salt. "All attempts," says Dr. Wight, "so far as I have been able to learn, to introduce this variety into India have failed; the pods are said to be blighted in the bud, and the few that attain maturity are generally more or less injured by the attacks of caterpillars: such, I have invariably found to be the case in all my attempts to raise it. The Egyptian, which, in that country, partakes of the valuable properties of this kind, is supposed to have been derived from the Sea Island stock: however, judging from some that I had sown in my garden, it has either got mixed with the Sea Island sort, or is in course of transition into it. The latter I rather suspect to be the case, but whether or not, it is most certain that, from a quantity of Egyptian seed sown in Madras, both 'Sea Island' and 'Uplands' were produced, and having the distinctive character of each strongly marked, even to liability to attack of insects." [The clothing of a seed with down is said to be a mark of very minor importance, as, it is now known, a single generation may change the seed from smooth to downy.] The "Uplands" or short-stapled variety of *G. barbadense* is reported as having thrived well in India, producing ripe pods in less than 3 months. It is added that the most advantageous time for sowing this is towards the end of the rains in December, or with the first of those in April and May, when they happen to fall freely.

The *G. acuminatum*, brought to India under the various names of Pernambuco, Peruvian, Bahia and Ava, is described as a very strong-growing plant standing high temperatures. It is probable, says Wight, that it merits, and will receive more attention, than has hitherto been extended to it. In the light sandy soil of the coast it seems to thrive remarkably well.

Both the Bourbon and short-stapled American cottons (as Sea Island) may, says, Dr. Wight, be successfully cultivated in our common alluvial soils, but more profitably in the red ones which are largely charged with the red oxide of iron: the long-stapled or Sea Island cotton has not succeeded in India, not because the plants are more delicate or less adapted to the climate than others, but because it is subject to the attacks of an insect, which deposits its eggs in the young fruit, causing blight.

The experimental farms for trial of imported varieties of cotton, principally American, established in the Bombay Presidency in 1829, proved to be an utter failure; but the cause of this is attributed to delay, spoiled seed, improper soils and bad seasons. There was moreover, no superintendence of any sort; no facilities offered, no encouragement held out; everything was left in the hands of the natives with all risks.

From the above quotations and epitomes of the experience of a botanist and experimentalist such as Dr. Wight, there is much to be got. His classification is certainly a desirable one, considering that both staple and appearance of seed are so apt to vary, and that the distinctive characters (first noticed by Roxburgh) are of a tolerably permanent nature. There are moreover some wrinkles as to suitable soils, and varieties worth cultivating. It will be observed that Dr. Wight favours the short-stapled American cotton, since he found that it matured its first crop with great rapidity, and produced a large proportion of staple as compared with other varieties; the only objection being that the seed had a lower nutritive value for feeding purposes.*

While seeking to introduce new varieties, the improvement of the indigenous cotton ought not to be neglected. There is always a price for it and a demand for mixing into American kinds. To this end soils should be manured, well ploughed or turned up.

* The tenacity with which the down clings to the seed of "New Orleans" has ever been a great objection with natives of India, who sell the indigenous cotton and use the seed as food for their cattle. The objection can, no doubt, be overcome, by careful ginning.—ED.

seed should be changed and that from other stock resown, and sowing should be systematically done and not carelessly, so that the plants may not choke each other in their growth, the young shoots should be topped when advisable, frequent weeding should be carried on, and the pods should be allowed to ripen on the stalk and not be plucked before they are ready. Tinnivelly is said to have fallen into disrepute during 1833-4 owing to cultivators plucking their pods green and then drying them in the sun.

These are considerations which intending cultivators would do well to take to heart. O. D.

"TIMEHRI"

RICE AND CACAO IN BRITISH GUIANA,
is the Journal of the Royal Agricultural and Commercial Society of British Guiana, which we always find full of interesting matter, including accounts of explorations of the colony and beyond its borders into Venezuela and Brazil. The number for June is enriched with a specially valuable paper by J. Rodway, F.R.S., on "The Schomburgks in Guiana," in which we have a romantically interesting account of the journeys and discoveries of the great man who connected the British colony with Humboldt's observations in other portions of South America, and whose name will ever be famous in connection with the great Victoria lily which he was the first to see, describe and introduce to Europe. Sir Robert Herman Schomburgk, honoured and pensioned by Britain, died many years ago, but of the two brothers who assisted him in his researches, one, Richard, lives as the able and still active botanist of South Australia, although in his 78th year. A valuable article on "opening up the country," by J. E. Tinne, mentions the fact that gold has superseded timber as the export next in importance to sugar and its allied products, and it is evident that Demerara is likely to contribute very appreciably to the gold stores of the world. In consequence of improvements in manufacture and in other directions, it is asserted, that sugar for direct consumption at 17s and 18s pays better today than it did ten years ago at 23s to 25s. The cultivation of rice and cacao is progressing, and a trade in fruit to the United States was likely to spring up. We quote as follows:—

The available land for settlement is already large but access to it is uncertain; and nowhere in the world is combined action more necessary or more difficult for small settlers, as regards drainage, water-supply, and sea defences, than in this extensive mud flat of British Guiana, with its land four feet below high spring tides, its very capricious rainfall of 70 to 100 inches, and its lazy but pleasant climate.

To us in Ceylon it seems strange that even coffee was grown successfully in the mud flats referred to as being in some parts absolutely under sea level. In an article on the rocks and minerals of this curiously fertile land, the geological characteristics of the alluvial deposits are thus described:—

The alluvial deposits consist of a recent alluvium in swampy districts and bordering small streams all over the colony, apparently of a very productive nature; of the fluvio-marine or coast deposit; of river loam along the courses of the rivers, and beyond the coast deposit; and of the valley gravel and the sand and clay deposit. Of these the coast deposit is the most important, since here are established the various plantations of the great industry of the colony. It extends along the whole sea-board, a few feet below the level of spring tides, inwards to a varying width of from 5 to 35 miles, where it attains a height of about 12 feet. Its depth is about 100 feet, and it consists of varying layers of fine sand and bluish clay, with portions of decayed vegetable matter. The surface soil of this deposit consists of a fertile dark-coloured loam on the estates; and beyond them, of a dark earth

made up largely of decayed vegetable remains. Many of the clay beds of this deposit are suitable for brick-making, while the bluish-clay below the soil, when burnt, is applied for the purposes of road-making. Contrasted with the mud deposits are the grand features of the new red sandstone formations:—

The most distinctive of the natural features of the colony, are found in connection with the various conditions of this formation; and denudation of a most active kind has been at work during vast ages to produce conformations as strange as they are magnificent, instanced best in those extreme examples, the perpendicular mountain, Roraima, on the inner confines of the colony, and the unique Kaieteur waterfall on the Potaro.

In the granitic rocks gold is widely and plentifully distributed and we should not be surprised to hear some day of a rush to the Demerara diggings. Small diamonds have been found in connection with the gold, as also impure graphite. There is an interesting account, by a Government surveyor, of three of the many rivers of this well-watered region.—In a fragment of Berbice history, evidence of our Dutch predecessors in the colony appears in the shape of notices of the "Burgher" militia and officers employed mainly to repress risings amongst the slaves. The Dutch Governor of "New Amsterdam" in 1799 was His Excellency A. J. Van Imbyze Van Battenburg. The scare about leprosy has spread to the South American colony and with good reason, for the late Superintendent of the Leper Asylums states that this horrible disease is so prevalent and so largely on the increase that at the present time one person in each 250 of the population is a leper. The disease was introduced by slaves from Africa. The remedy is strict isolation: the only tribe of Indians among whom cases appeared had mixed freely with negro lepers. There is an exciting account of a fight between the British ship "Peacock" and the American "Hornet" in 1813 off Demerara, the result being the destruction of the British ship and the death of her commander and most of the crew. The details of the desperate contest are most sickening, and such as we trust may never be repeated. In regard to the celebrated fight between the "Shannon" and the "Chesapeake," in which the British were victors, our readers will be astonished to learn that the Nova Scotian Second Lieut. Wallis, who carried the American vessel into Halifax, yet lives as Sir Provo William Parry Wallis, G. C. B., Admiral of the Fleet. He is in his 99th year. There is a most interesting account of a trip up the Essequibo and Potaro to the great falls, from which we should like to quote if we had space. British Guiana is still a land for exploration and description, rich in woodland, river and mountain scenery, and in natural history, while the rocks are full of varied and valuable minerals. The colony has held its own through the sugar crisis, the energies of the colonists being aided by science; and it seems beyond question that there is a great future before the British possession in South America, which in slavery discussions was often referred to as "one of the fine islands in the West Indies."

PLANTING IN TAVOY, BURMA.

Mr. J. D. Watson writes under date Sept. 13th:—"Coffee here A 1, now out in a splendid blossom again, and it will be in full bloom by next month. Liberian coffee simply splendid, great trees and are to bear heavily. Tea flushing well, a great strong vigorous leaf. Vanilla growing well and will succeed. Oubeb pepper of much value, I have been fortunate to get and have it growing, and it is also to do well. Cacao will do splendidly with proper shade. I am now planting the rain tree and Inga.

I have planted a large acreage in Hevea rubber and have it up already from seed and planted out as well as planted at stake; 20 trees in Mergui gave 1½ viss. Coconut do well and also betelnut trees and fruit trees. I have of all sorts doing splendidly: Penay jak and Ralah jak and orange trees and limes bearing very heavily. Annatto is splendid and the price not so bad considering the little attention it requires. I am putting up a new store and rupees are scarce at present."

THE COFFEE CROP IN COORG.

From the returns furnished from the principal firms on the west coast as well as at Bangalore and Mysore, it appears that the aggregate export of plantation coffee from Coorg to the curing firms on the coast and at Bangalore, &c., for the season of 1888-89 is shown to be 1,694 tons distributed as follows:—

	Tons.
Exported to west coast	1,098½
„ eastward	595½
TOTAL	1,694

The above figures do not include the bulk of the native coffee, which, by reference to the Toll-gate returns, may be taken at 1,067½ tons, making an aggregate export of 2,761½ tons. The statistics collected at the several Toll-gates show the following results:—

EXPORTED WESTWARD. 1888-89.		Tons.
Watekolli (Perambady)	1,393½	} 2,251
Sampaji	857½	
EXPORTED EASTWARD.		
Anechowkur	228	} 510½
Siddeshwara	171	
Fraserpet	8½	
Kodlipet	103	
TOTAL	2,761½	

The area of European Estates actually planted is returned as 28,636 acres. The corresponding area of native holdings is computed at 31,393 acres.

The forecast of the coffee crops for 1889-90 stands as follows:—

Forecast of yield as obtained from Planters' returns	Europeans	2,034
Forecast estimated for area for which no returns have been furnished.	Europeans	1,542
	Natives	3,139
Total forecast for 1889-90.	Tons	6,715

Estimated average yield per acre of ordinarily well-cultivated coffee in full bearing for 1889-90. 4¾ cwt.

Return of export of coffee from Coorg last year, 1888-1889, taken from the toll-gate returns. 2,761½ tons.

Return of export of coffee for 10 previous years } 42,527 tons or 4,253 tons annual average
 Taking the average or 1 rupee crop at 4,253 tons per annum, the forecast of 6,715 tons for the coming season represents R1½ or 24 annas crop, the anna equivalent being 6,715÷24 or nearly 280 tons.—*Madras Times*, September 26th.

ENEMY OF THE COTTON PLANT.—An Udupussellawa planter sends us "cotton plant leaves, Sea Island jât," eaten by some insect, and asks "What is the poochie?" But he will require to catch some specimens of the latter and send them for identification say in a match-box.

ROYAL GARDENS, KEW.—The Bulletin of Miscellaneous Information for September contains:—"Flowers of Calligonum as an article of food in N. W. India.—Earliest notice of Coca.—Buazé fibre. Vegetable Productions, Central China.—Vine cultivation in the Gironde.—Phylloxera in South Africa.—Erroneous Report of Phylloxera in Greece."

Correspondence.

To the Editor.

HOOLOKANDE TEA AND CEDARWOOD BOXES.

DEAR SIR,—My attention has been drawn to the average of the last "Hoolo" break as given in circulars, viz. 1s 6½d. As a matter of fact, had auction room bids been accepted, the break would have realized over 2s per lb.; but as the tea was considered worth even more, it was withdrawn and was ultimately disposed of for 1s 10½d.

So much is of no interest to the public; but when it comes to be known that the greater portion of the tea was in Japan cedar boxes, the matter acquires some interest.

It will be noticed that the tea was considered worth 2s in the auction room;

The withdrawal of the tea seems to have been the cause of offence; for not until the tea was withdrawn did buyers become aware of a taint.

Now whether this was merely a case of "Bearing" or whether from the packages being left unsealed for the extra day or two the tea did actually acquire a taint; is a matter which cannot here be decided; but that there is a distinct prejudice, whether rightly or wrongly, against the cedar packages, must be recognized by all: however careful the packing, it will be worth while to consider well the risk of real taint, or the cry of wolf that may be raised. E. G. R.

The above is the only lot of Hoolo tea that has been packed in cedar for about 4 years.

STATEMENT OF EXPORTS FROM THE MALABAR COAST SEASON 1888-89 ENDING 30TH JUNE 1889.

Tellicherry. 5th September 1889.

DEAR SIR,—Together with this we have the pleasure to hand you our Annual Statement of Exports of Coffee and Pepper from the West Coast for the year ending 30th June last.

Coffee.—From the figures given you will gather that the quantity of coffee shipped during the past year falls considerably below that of the previous years' shown in the statement, and we may add that that shipped for the past 15 years. The export from ports south of Calicut is steadily dwindling, and the crops in Mysore, Coorg, Wynad and the Neigherries on which the northern ports depend were generally most disappointing, although the prices obtained for them compensated owners to a certain extent and enabled them to continue a system of liberal cultivation upon which the future of the coffee enterprise in Southern India entirely depends, for we cannot hide from ourselves the fact that leaf disease is making headway even in well shaded districts, such as Mysore and Coorg, where we fear our planting friends do not as yet sufficiently recognise the evil. Borer has also been virulent and a large number of trees have had to be taken out in consequence of it.

In regard to prospects the blossoming showers were generally late, but when they did come the show of blossom justified planters in expecting a heavy crop, but we are sorry to add that estimates have been considerably reduced all round and although a greater quantity will be exported than last year, we anticipate the total shipments from the Coast will not exceed 320,000 cwt.

Pepper.—The amount exported is no criterion of the actual crop gathered, for as prices fell, native producers ceased to bring it into the market, and we know as a fact that a very large quantity of last year's crop is being held in North Malabar alone, it being an article that does not deteriorate with keeping. The crop now on the trees promises to be a large one and we anticipate heavy

Shipments the coming season.—We are, Dear Sir, Yours faithfully p. pro. ALSTON, LOW & Co., RALPH TATEHAM.

DAVIDSON'S NEW DOWN-DRAFT SIROCCOS.

DEAR SIR,—Although there are several of Davidson's new down-draft Siroccos now in use in Ceylon, we have not yet seen publicity given to the results obtained from them, so with your permission we will supply the information, which, doubtless, will interest all engaged in the tea industry. The down-draft Sirocco was designed to dry tea with a rapidity hitherto unapproached by any other drying apparatus, its construction being such that three or four times the quantity of hot air can be drawn through the tea without disturbing or blowing the leaf off the trays, compared to what can be attempted with any apparatus employing an up-draft through the tea; and the results so far obtained have been eminently successful.

In May last, in the valuation of a sample of tea dried in the down-draft Sirocco at Elbedde Factory, and a sample of the same leaf manufactured in the ordinary up-draft Sirocco, also at Elbedde, the local brokers made a difference of 4 to 6 cents per lb. in favour of the "d.-d.," but this was only what Messrs. Davidson & Co. expected, as the operation of the machine in drying tea thoroughly and perfectly in 8 minutes, and at a temperature of 240 F, as compared to the up-draft sirocco doing the same work in 25 to 30 minutes, necessarily produces a higher quality of tea from similar leaf. The machines at Elbedde and Moray did not at first, as far as quantity was concerned, give the out-turn estimated, but this was due to the fact of the fan being driven at too low a speed. The drive at Elbedde on the occasion referred to was very unsteady, varying from 600 to 900 revolutions per minute, in place of having a steady run of 1,200 revolutions. Later reports from the same estate are, however, still more encouraging, the broker putting even a greater difference in favour of the down-draft teas as compared to the samples from the updraft machine.

Since the receipt of the foregoing information, Mr. Maguire (Messrs. Davidson & Co.'s representative now in India) reports that at one place (Kopati) the "d.-d." gave an outturn of 220 lb dried tea per hour, using only 169 lb of wood fuel. This is indeed an extraordinary result. On the whole the average of Mr. Maguire's reports show an out-turn of 127 lb dried tea per hour with a fuel consumption of 104 lb. wood, fairly realizing the estimate, both as regards quantity of tea dried and fuel used, formed by Messrs. Davidson & Co.

From the information afforded by Mr. Maguire, the fireplace, stove and fan of the "d.-d." for the coming season, will be enlarged, and owing to the sharp increase in price of iron and steel, and workmen's wages, the price of the machine has been advanced to £150. Even at this price the "d.-d." sirocco will bear very favorable comparison with any other drier in the market, especially when it is known that the new apparatus will not only turn out an average of 160 lb. made tea per hour, but is stated by experts to improve the quality, as compared to drying in any other machine, to the extent of 1d to 2d per lb. In addition to Elbedde and Moray, one of the new machines may now be inspected, per favor of Mr. R. W. Wickham, at Holmwood estate, Agrapatana.—Yours faithfully,

W. H. DAVIES & CO.

MODERN SANITARY SCIENCE ANTICIPATED
IN MOSAIC LEGISLATION: STRICT EXAMINATION OF BUTCHER MEAT NECESSARY.

Kandy, Sept. 18th.

DEAR SIR,—Man does not live on bread alone and John Bull is known to evince a partiality for

roast beef. It behoves the beef-eating section of our community therefore at this season, when cattle murrain is raging all over the country, to guard against the dangers arising from this source, both immediate and remote. Now as the beef-eating section comprehends those in authority and power in the land in its category, there is consolation for the masses, that the matter will be taken in hand both by the municipal authorities as well as by the legislators of the land. They need go no further than copy the precepts of our venerable lawgiver Moses, a figure in ancient history familiar to every schoolboy. This remarkable man, it appears, centuries ago before scientific knowledge and the microscope led to the startling discoveries relating to lower organisms, laid down certain prohibitions regarding the eating of the flesh of certain animals, touching the draining of the blood and the testing of certain organs to ascertain the state of health of cattle slaughtered for food, which would fill our modern legislators and sanitary officers with astonishment to learn at the present time. In a paper presented to the Academy of Medicine, Paris, in 1885 by Dr. Noël Guéneau de Mussy, he detailed certain information on the authority of the Grand Rabbi of France, regarding the method of slaughtering and examining cattle adopted by the Jews. In this paper, from which copious quotations are made by Dr. Behrend, M. R. C. P., in his article, "Diseases Caught from Butcher's Meat" in the September number of the *Nineteenth Century* to hand this day, the following passage occurs:—

"The idea of parasitic and infectious maladies which has conquered so great a position in modern pathology, appears to have greatly occupied the mind of Moses, and to have dominated all his hygienic rules. He excludes from Hebrew dietary animals particularly liable to parasites; and as it is in the blood that the germs or spores of infectious disease circulate, he orders that they must be drained of their blood before serving for food.

"The Talmud, a commentary on the Mosaic law, prescribes an examination of the principal organs especially the lung, rejecting such as have adhesions, either between the tissues of the lobes themselves or between them and the ribs, and also if there be pustules disseminated, even superficially, in the lung. The lungs must be insufflated, and its expansion so perfect that any rupture of its substance however minute, suffices for its condemnation as impure, and, to avoid all chance of error, the insufflation must be conducted under water. These ordinances are to this day observed by Israelites faithful to the law; and duly appointed officers to visit the slaughter-house to superintend their execution.

"The chief rabbi of France says, that sometimes as many as 26 out of 30 cattle are rejected on account of pleural adhesions.

"What an extraordinary prescience! The contagion of tuberculosis has been proved only during the last few years; its transmissibility by food is not yet universally recognised, though the experiments of M. Chandveau render it almost certain; yet the law of Israel, thousands of years in advance of modern science, had inscribed in its precepts these ordinances, preventive of the malady. For if such adhesions have any other causes besides this presence of tubercle, this is by far the most common; and though adhesions may exist without tubercle, the latter is very rarely present without the former.

"Here then we have an easy and practical method, within reach of ignorant persons, of removing from food supplies the flesh of tuberculous animals, and for further security this law, in addition to and even in the absence of such adhesions, pro-

Leghorn, 250 cwt. Tellicherry and 325 cwt. Calicut Pepper. For Rotterdam, 100 cwt. Tellicherry Pepper. For Alexandria, 100 cwt. Tellicherry Pepper. For Messina, 10 cwt. Cochin Pepper. For Suez, 817 cwt. Tellicherry Native Coffee and 375 cwt. Pepper; 48 cwt. Calicut Native Coffee and 63 cwt. Pepper. For Turkish, African and Arabian Ports, 740 cwt. Cannanore Pepper. For Bombay and other Indian Ports, 20,282 cwt. Cannanore Pepper. For Bombay and other Indian Ports, 1,165 cwt. Badagara Pepper.

nounces as impure and unfit for food, animals, whose lungs show pustules or excrescences disseminated in their surface."

Time prevents my continuing this subject further today, as I am writing for today's post. Let us hope that although the Government may not have a soul to be saved or a body to be kicked, yet, as it is composed of individuals whose bodies are nourished with solid beef, they will see to the matter for their own sakes.

It has been stated in certain quarters that it was time pressure was brought to bear on the authorities, or that the Governor should be petitioned. I hardly think this necessary: we are all in the swim.—Yours truly, B.

CAPE COLONY.—Professor MacOwan contributes to the Departmental Agricultural Journal an interesting article on Apple-scab and other diseases caused by fungi in Apples and Pears.—*Gardeners' Chronicle*.

SINGAPORE.—The annual Report of the Botanic Gardens, Singapore, has reached us. It is mainly occupied with details of the routine work of the garden which show that the newly-appointed Director, Mr. H. N. Ridley, is alive to the duties of his office.—*Ibid*.

JAMAICA.—The prize for the best sample of Tobacco, 400 lb in weight, has been divided equally between Jamaica and North Borneo. The last number of the Botanical Department Jamaica, contains a full account of the method of culture and preparation, from the pen of the late Mr. J. O. Espin, a Oulan, who was engaged in the culture in Jamaica.—*Ibid*.

THE FUTURE OF QUININE.—The New York correspondent of the *Chemist and Druggist* cabled on August 29 that the only notable news in the drug market on that side was that a further advance had been effected in quinine, and that dealers regarded the future of this article with much confidence. The same journal mentions that a gentleman who has recently visited the Ceylon estates reports that he does not see how the planters are to send away much more than 6,000,000 lb. of bark next year, most of which will come from healthy trees.

TEA FROM YOKOHAMA, JAPAN.—The export of tea amounted to 23,808,714 lb., valued at £559,628, as against 26,557,616 lb., valued at £732,348 in 1887. The tea season of 1888-9 opened auspiciously for exporters last April, and so continued in May and June, prices here declining; but owing to the rapidity with which supplies were poured into the markets of the American continent a glut was the result, and holders became too eager to realise. Auction sales in Chicago and New York, coupled with extravagant rumours which prevailed relative to the crop, further contributed to disorganise the market for a time. Since the summer, a firmer tone has prevailed in the consuming markets. The quality of the leaf was a fair average throughout the season.—*Japan Weekly Mail*, Aug. 31st.

OVER-POPULATION AND EMIGRATION IN JAVA.—A pamphlet in Dutch on this subject, by Mr. R. A. Eekhout, Hon. Secretary of the Soekaboem Agricultural Association, has been sent to us by the author. It contains three papers (reprinted from the *Bataviausch Handelsblad* of 29th April, 15th May and 29th June 1889), headed respectively "Increase of the Population of Java," "Emigration of Chinese to Netherlands India," and "Emigration of Java's Surplus Population to the Outside Possessions." In two places Ceylon is mentioned: in one, the writer doubts if in our island (as in Java) large numbers of natives are to be met with on the public roads suffering from horrible diseases; and in the other the emigration of Tamils to Ceylon is referred to. Mr. Eekhout urges on the N. I. Government the formation of an Emigration Board such as exists in British India.

COTTON IN CEYLON.—The Lancashire people are very much interested in the cotton manufacturing enterprise recently started in Ceylon, and they are feeling its extension. The good people of Ceylon may grow as much cotton as they please, but if they, following in the wake of India, are going to start cotton mills, the outlook for Lancashire will not be cheerful.—*H. & C. Mail*.

INDIA-RUBBER AND GUTTA-PERCHA.—Messrs. Ferguson, of Colombo, have done good service by publishing a second edition of their treatise, which is a summary of information compiled from various sources as to the natural history and cultivation of the trees. Messrs. Haddon & Co., of Bouverie Street, are the agents for the work in this country.—*Gardener's Chronicle*, Sept. 7th.

PURE ARROWROOT FLOUR.—Mr. R. P. Jayawardene of Cotta has had reasons to suspect the purity of the stuff sold in the native market as "arrowroot" and had been induced to attempt to produce a really pure supply of an article so largely recommended by medical men. The arrowroot of the native market is largely adulterated with the starch of the sweet potato, the cassava, and rice, an article which the doctors recommending "arrowroot" would hesitate to permit their patients to take. The lowness of the price, viz., 12 to 20 cents the pound is sufficient evidence of the inferiority of the stuff; a pound packet of Mr. Jayawardene's article known as "Jayawardhanapura arrowroot" is 35 cents.—*Cor.* [We have a good report from a housekeeper who has tried Mr. Jayawardene's arrowroot in several ways. She finds it much purer and whiter than what is bought at the door and can recommend it as probably equal to and much less expensive than the West India arrowroot in tins.—*Ed*]

QUININE IN INDIA.—It is very satisfactory to learn how the missionaries (both ladies and gentlemen) are extending the use of quinine among the people both in India and China, by taking supplies for distribution on their evangelistic journeys. Miss G. M. Fletcher, in giving an account of work in the villages near Delhi, mentions that during five months of tentwork, as much as 14 lb. of quinine were distributed among 600 patients, and that the people now come regularly for the fever medicine to the B. M. S. Dispensary in Delhi from the region round about. If quinine were freely distributed among the people of China, especially in the low marshy districts, there would soon be a stop put to the opium traffic, and the same may be said of laudanum-drinking in the Fen districts of England if the people were only induced to try quinine instead.

THE WEIGHTS OF CEYLON TEA PACKAGES.—The following extract from the *Produce Markets' Review* should have attention and consideration at the hands of Ceylon Tea planters:—"The large variations in the weight of teas packed in Ceylon, which necessitate turning out and reweighing on arrival here, call for special attention on the part of tea planters, and the subject has been exhaustively dealt with in Messrs. I. A. Rucker & Bencraft's Circular of June 27th. Beyond their own interests, however, the planters would do well to consult the convenience and wishes of the Grocer, whose predilection lies strongly in favour of increasing the average net weight of half-chests to at least 60 lb. This sized package can be easily handled, and the carriage on the net weight of tea would be less than in the smaller packages, while the saving in labour would be considerable, and the weight would coincide with that of half-chests of China Tea, by which standard the Grocer is accustomed to buy. As regards Dock charges, a package of 89 lb. gross is charged only 5s 2d, as against 4s 8d for one of 60 lb. gross, and the rent is the same as for one of even 45 lb. gross, namely, 1d per week. Thus the larger package is not only more acceptable to the Grocer, but by far the most economical for the importer."

THE TRADE OF SIAM.

Siam, like other Eastern countries at the present moment, exhibits signs of commercial prosperity, in which British merchants take the largest share. According to Mr. Gould's last report from Bangkok, while German tonnage decreased 19,939 tons, that under the British flag increased by 26,585 tons. At present the carrying trade is as to 63 per cent. British, 21 per cent. German and 8 per cent. Siamese. The exports of Bangkok were larger than any previous year, amounting to \$16,842,026, mainly on account of the very large export of rice, which reached 449,589 tons. There was also an increase in teak, due to the favourable state of the river, which admitted of larger quantities being floated down; the trade in bullocks also showed an enormous development, amounting to 27,118 against 15,263 in 1887. Vegetable dye materials, gamboge, indigo, &c, in Siam, as elsewhere in the tropics, show no increase on account of the increasing employment of chemical dyes. The railway surveys for possible lines to Chienmai and other northern and eastern provinces of Siam, initiated by Sir Andrew Clarke, are being rapidly carried out by a large staff of surveyors. Sapphire and ruby diggings also proceed with fair success. Most of the rubies are small, and have the same fault as the sapphires, being as a rule too dark. The commoner stones go to Switzerland, the better class to India. Both sorts are now found over a wide tract of country, the diggers are all natives of Pegu, as they alone are able to withstand the bad malarial fevers of the diggings. Chinese coolie immigration is on the increase; secret societies are spreading among them, and Mr. Gould, writing some weeks before the recent outbreak, expresses the opinion that some day very serious consequences may arise from the action of disorderly Chinese coolies in Bangkok.—London Times, Sept. 3rd.

ORANGE CULTIVATION IN SICILY.

The United States Consul at Messina, in a recent report, states that the province of Palermo is the great orange district of Sicily. Throughout the province of Messina the orange was exterminated in 1865-70 by the "gum," and the lemon budded on the wild orange has taken its place. The Sicilian grower prefers running the risk of damage by frost, which, however, is small, to gathering his oranges when they are still immature. Sicily oranges, which are, of course, not fully ripe when gathered, keep well for 40 days. Frequently the fruit when gathered is allowed to sweat in the groves from two to three days, piled on the ground and covered over with tarpaulins; it is then wrapped in tissue paper, put in boxes, and sent to Messina. Fruit is also sent directly from the groves. All fruit upon reaching the exporters' warehouses is carefully inspected and selected, wrapped in fresh tissue paper, and repacked. Exporters ship their oranges as soon as packed. During the shipping season large firms in Messina employ as many as 300 women and girls, paying them 10d to 1s a day of nine hours' work. The women select and wrap up the fruit. Men are employed to pack the fruit and handle the boxes. The stevedores handle the boxes with great care, and the steamers give all possible ventilation to the fruit during the voyage. Fruit possessing the greatest keeping qualities is sent in sailing vessels to the United States. Exporters frequently buy the fruit on the trees. The cost of preparing and shipping a box of oranges or lemons to New York is about 4s 6d. Years ago oranges were preserved in sand for from four to five months for family use. This practice no longer prevails, as it would not pay on a large scale; such enormous ware-

houses would be required and so great would be the expense of handling the fruit. Preserving oranges in bran has been tried, but it proved too heating. The soil has great influence upon the maturing and keeping qualities of oranges. The fruit ripens earlier on light sandy soil than on clay soil. Fruit grown on the former cannot be left long on the trees without deteriorating in quality, whereas on stiff clay it can remain with impunity until the end of April. The former kind is small and of a pale yellow, and keeps only for a short time, while that grown on a clay soil is large, keeps well, and is of a reddish colour. The fine large oranges that bring a high price in Palermo in summer are allowed to remain on the trees until the end of May, when they are stored in subterranean grottoes. They are produced on clay soil abounding in alkalis and well-decomposed organic matter. In the sides of the mountains near Palermo are many grottoes that are cool and well ventilated, in which oranges keep well during the summer; they are spread two layers deep upon large mats placed at convenient distances one above the other. Every day or two the fruit is turned over and all the defective oranges are removed. This fruit finds a home market.—London Times, Sept. 3rd.

COFFEE IN AMERICA.

The imports, as reported by the United States Bureau of Statistics, for the year ending June 30th, 1889, were 578,397,454 pounds, valued at \$74,724,882, against 423,645,794 pounds, valued at \$60,507,630, for the preceding year. These figures show an increase of 154,751,660 pounds; a difference in supply sufficient to explain market variations during the past two years.

The exports of coffee for the same period were 17,265,354 pounds, against 15,083,019 pounds in 1888, a gain of 2,182,335 pounds.

The imports for the trade year recently closed are the largest on record. The consumption, assumed to be the imports minus the exports, was 9.2 pounds per capita, against 6.89 pounds in 1888; 8.36 pounds in 1887; 9.2 pounds in 1886; 9.45 pounds in 1885. The short crop and high prices in 1887 sent the per capita consumption far behind previous years, but this has been regained. If the crops of this year prove to be below the world's average annual requirements, we may reasonably expect a decline in consumption as a partial offset against a short supply.

We here present a table showing the exports from Brazil for the past five years:

Year ended June 30.	Rio.		Total.
	Bags.	Bags.	
1889 ...	3,874,000	2,557,000	6,431,000
1888 ...	1,879,174	1,310,209	3,189,383
1887 ...	3,423,353	2,493,228	5,946,183
1886 ...	3,642,202	1,660,169	5,302,871
1885 ...	4,093,889	2,175,627	6,269,516

Total five years...16,942,618 10,196,233 27,138,851
 Annual average... 3,388,523 2,039,247 5,427,770

Coffee plantations in Brazil and Central America are paying their owners handsome returns. It is natural under such circumstances that the area devoted to coffee should be extended, and this we know to be the case in Central American countries and in India. It can only be a question of a few years when coffee production will again run ahead of consumption.—American Grocer.

THE NORTH BORNEO TOBACCO CROP.

Telegraphic information has been received from London to the effect that the Darvel Bay Co.'s first crop of tobacco has been sold at Amsterdam at the exceptionally high rate of 2s 5d. Although it was well-known that the quality of the produce was really first class, it was not expected that more than 1s 8d would be realised. This ought to prove very encouraging to those interested in the success of the tobacco industry in British North Borneo. Mr. Walker, of the Sandakan Land Office, estimates the North Borneo

Tobacco crop of 1889 at 300 tons, which at two shillings per pound, will realize £67,200. From recent sales, it would appear that a larger price may be expected.—*Hongkong Telegraph.*

NOTES ON PEPPER CULTIVATION IN MALABAR.

BY PETER PIPER.

Dedicatory Ode; Composed by my Nursery Cooly.

Sing a song of pepper
Cuttings on the rot,
Six and sixty acres
All gone to pot;
When the berries ripened
Up rose a gentle Mop,
Smiled and picked and sweetly said
"What a paying crop."
The vines are on the mountain side,
The soil is in the valley,
The standards tumble right and left
Like skittles in an alley;
In the nurseries are the seedlings
Nicely on the grow,
In stalks a sick cow
Eats the blooming show;
The planter in his bungalow
Discusses ruination
In the clearings the buffalo
Oh!—the joys of cultivation!!!!

During the past three years it has been part of my duty to superintend a pepper estate and to inquire of my native neighbours the treatment necessary for the proper cultivation of this vine. By pepper, I of course refer to *piper nigrum*, a vine extensively grown throughout Malabar, but more especially in North Malabar. The fruit of this vine is the pepper-corn; it is produced on aments or catkins and not, as so many people think, in pods. I may here incidentally remark that white pepper is the same berry, only with the outer skin or pulp washed off. The nearest resemblance to a pepper catkin just before the berries ripen is perhaps a bunch of unripe red or white currants. The vine with even dark green heart-shaped leaves is somewhat reminiscent of ivy, and as it clothes the trunks of almost every tree except the palms, and sometimes even these, it adds greatly to the picturesqueness and rich verdure of this land of orchards. If any one should require further particulars, correctly and botanically expressed, are they not written in Roxburgh and Drury?

I do not propose to treat of the part this spice played in Rome's ransom or the past history of India, but merely the part it will play in the future of the Indian planter. And it will be a great part, I verily believe. Black pepper may be fairly called "the spice of life"; for it is as indispensable for an immortal creation of a private-brougham *chef* as for the homely stew of the frugal housewife; it is as eagerly eaten in the palaces of Pekin as in the boarding houses of Chicago; it is as highly appreciated by the aborigines of Africa as by the millionaires of Australia. As each year new markets are opened in Central Asia and the heart of Africa, the demand for pepper will increase. The present price in London, calculated on the same basis as the daily quotation of M. P. Coffee, is 70s per cwt. The vine grows wild, to my certain knowledge, from the sea level to an elevation of 5,500 feet, but it is in those steamy valleys, with their rich soil, lying at the foot of the Western Ghats, that it will flourish and pay best, both on account of prolific yield and pungency of flavour.

Cultivation in its present meaning is a term you can apply to no native tillage, is a remark I re-

cently heard made by a friend whose opinion commands consideration. If this is so, and I concur in it, how can one except cultivation to be practised in a district teeming with life "flowing, if not with milk and honey," at least with water and molasses, where for many months in the year the very stones are "all a-blowing and a-growing!" Nor would the pepper vine be an exception. The trees to which it is most commonly wedded are the jack and the mango, the two favorite fruit trees of the country, yet their fruit is today as fibrous or as foetid as when they were first brought from the jungle. My argument then is that, though pepper has been grown for many centuries, its cultivation is yet in its infancy, and that less can be learnt from, than what there is to be taught to, native growers. They have a rough cultivation, and they are always very willing to tell you all they know. But ask them the reason for anything, and you are at once stopped short by that blank wall of an answer "Cos why."—*Madras Times.*

ARRIVAL OF THE VICTORIA REGIA FOR THE COLOMBO FORT GARDENS.

The plants of *Victoria regia* for the Fort Gardens arrived at Colombo on Saturday (Oct. 5th) having been brought down from Madras by Dr. Thurston. They are in first-rate condition, having stood the voyage very well indeed. They will be ready for planting in the course of a week or so as soon as they have got fresh roots. It is a pity the water is not in the tank yet, but it can be let in at almost any time now. The soil has to be prepared, but there is not much trouble about that. Dr. Thurston thinks the tank will be a first-rate place for these magnificent plants. Mr. Nock of Hakgala was down on Saturday to see about them.

The leaves of the *Victoria regia* sometimes attain a dimension of over 6 feet in diameter. It is a circular leaf, with the edges turned up about an inch all round, and one leaf will easily bear a weight of 25 lb. Indeed one might think it was a leaf of this sort that Moses was put into on the Nile. The blossom, when it comes out, is very beautiful, and the scent of one flower will be felt all over the Fort, we are told. The flower continues in bloom for five or six months at a time.

It was very fortunate that Dr. Thurston was able to bring the plant down, as it is of a very delicate nature, though, from its size, it might not be supposed to be delicate. It was brought down in a special Wardian case.

TEA NOTES.

(From the *Indian Planters' Gazette.*)

DEHRA DUN, 17th Sept.—This last week we have had 4.20 inches of rain. The rains are nearly over now, and we are having lovely weather.

LALLAMOOK, 15th Sept.—Our rainfall for the week has been 40 inch only. Total 79.25 inches; last year 126.24 inches. About 81 inches is our average rainfall to this date. Leaf is not coming on fast.

MANGALDAI, 16th Sept.—The feature of the week has been two fine days. Rain commenced again after 36 hours and has fallen more or less since, at nights. Tea is generally going back. The nights are getting perceptibly cooler.

COFFEE NOTES.

(From the *Rio News*, Aug. 12th.)

Our American exchanges are counting on an increased crop of coffee from the West Indies and Central America for the coming year.

A patent has been granted here for the construction of a locomotive coffee-cleaning mill. It is proposed to fit up a railway waggon with machinery and instead of the planters being obliged to send their coffee to the mill, the mill will be sent to the coffee; precisely as was the case with Mahomet and the mountain.

It is very evident from the tenor of our American exchanges that the coffee trade there has not yet become persuaded that a coffee famine is imminent. The New York *Commercial Bulletin* and the *Shipping and Commercial List* are decidedly "bearish" and their influence on the real traders in the bean is sure to be a serious feature in the market.

We are informed by various parties who have travelled through the interior that the appearance of the coffee plantations is very irregular. In Minas and Rio there are districts where the trees appear to be hopelessly dried up by the drouth, while others still show life enough to yield a moderate crop if the rain should soon put in an appearance. In São Paulo the Plantations are in better condition and the new orchards may be expected to make up a good part of the deficiency.

The statement made by us, six months ago, has been confirmed as regards the coffee beans of the present crop (1882-90) being to a large extent *quakers* due to the exceptional drouth at the end of last and commencement of the present year. The actual hulling is showing that instead of five *quartas* (of an *alqueire*) producing, as in preceding years, an *arroba* of clean coffee, for this crop to produce the same weight from seven to eight *quartas* are required.—*Jornal do Commercio*, Aug. 10th.

SPORT IN TRAVANCORE.

Mr. Harry M. Knight writes to us as follows:—

"In your issue of 21st August you recommended these parts to Ceylon sportsmen for elephant and *cheetah* hunting. Let me warn them that shooting here is much harder work than in the lowcountry of Ceylon and game generally speaking not so varied. Elephants are conserved by the Sircar and "permits to shoot" only granted when damage to property is proved, and then only on condition that the ivory and teeth are handed over to the Sircar if the grantee be in luck. Bison, however, is the game "par excellence," and the following account of two successful days after them may interest your readers. The first day I intended to prospect more than shoot, because I had only a .450 Winchester repeater available, but after 7 hours hard climbing over very rough ground, could not resist the temptation to stalk a herd of 7 bison and a calf lying down on the opposite face of hill (yelept Neddampara). Getting to within 80 yards I fired at a young bull standing nearest me, but doing no damage repeated dose with same result, when to my amazement a splendid bull arose apparently from the ground to protect and cover the retreat of his beauties. He staggered to my first shot and the second brought him on to his hind quarters at 150 yards and then the fun began, eventually bagging him after 16 shots.

"The bull killed last week was a most venerable and ancient beast. The first shot fell to my lot, but I was unable to accept the office on account of the nimbleness of my gun-bearer who sought his safety and my jeopardy in flight, so that C.W.B managed to get in two well-placed shots, the latter of which grassed him just as he turned to charge, when we finished him off, the trophy falling therefore to our latest arrival from your island to swell his already numerous collection:—

8	0	... Breadth of horns...	...	2 10
0	0	... Widest part forehead	1 0
1	5½	... Round base of horns	1 8
6	8	... Height	5 8

SUMATRA TOBACCO ON FLORIDA.—The Quincy *Herald* gives a very glowing account of the tobacco crop of Gadsden county. The yield is large. On all the plantations new barns have to be erected to hold the crop. The area planted is 2,000 acres. The imported Sumatra seed has done well, and large fortunes are in sight for the planter. Why should our rich tobacco lands go to waste?—*Ocala Banner in Florida Despatch*.

COTTON CULTIVATION.—A missionary who travels about a good deal writes:—"We are trying to induce the villagers to plant cotton, but they are exceedingly conservative, and stick to their paddy cultivation, although the returns are so poor. As I walk through the fields and see the thin crops on which they depend, I often feel much pity for them, and never lose a chance of saying a word for cotton. The fact is, that these people made something by their coffee-gardens in former years, and it may be that the failure of that, which really brought in a fair return in many cases, discouraged them from attempting any other 'new product,' so that they hang on with their rice between fever and starvation. I think the Government have done wisely in appointing Mr. H. Lewis, late of the Agricultural School, to be Sub-Inspector of Schools for the central districts, and I hope he may be useful in giving an impetus to cotton-cultivation, &c."

POTTERY.—Government has approved the proposal of the Director of Public Instruction to add pottery to the list of trades specified in the Grant-in-Aid Code. Mr. Grigg in submitting his proposal remarked.—"Pottery and porcelain manufacture are included in the subjects of the higher technical examination, but pottery is not at present open as a subject to industrial schools. This seems to me a serious defect, and I think there is reason to expect that if it is included in the subject open to such schools it will be taken advantage of. I am making a beginning in the School of Arts and for that institution the proposed tests are needed. The principle which I should think guide managers in introducing industrial teaching is that the industries in which instruction is given concern products which are in general if not universal demand. In this respect, pottery has few rivals."—*Indian Agriculturist*. [This example ought to be followed in Ceylon.—Ed.]

TEA TASTING.—On the subject of tea tasting a correspondent of the *Grocer* writes:—"Many of your readers must be unaware of the perfection of palate which habit, orderly living, a sound stomach, and good teeth enable some experts to attain. A marvellous instance came under my notice the other day. In one of the leading firms in the trade a discussion had arisen as to the relative merits of five parcels of fine Moning, all about the same price and flavour, whereupon one of the 'palaticians' connected with the firm offered to take two to one he would pair the five, *i. e.*, ten cups. In this he just failed, three only being right, whereupon another 'palatician' engaged in the firm pluckily laid two to one on himself, and did it in a canter. This so nettled number one that he insisted on a second try, backing himself at even money, and winning in a walk. A peculiar feature in the matter is that both gentlemen have very fair complexions, and it is certainly the writer's experience that fair men (not red) make the best tea-tasters. Anyhow, trade experts will recognise the brilliancy of this performance, and though the identity of the plucky little champion number one may not be revealed, as like a modest moss-rose, he prefers to blush unknown, plenty of his admirers will be prepared to back him.—*H. & O. Mail*, Sept. 6th.

QUININE PROFITS.—We are informed that the amount of 184, 126m. (9,263l.), which we stated last week, on the authority of a German journal, to have been the profit of the Auerbach Quinine Works during the financial year 1888-9, has been the gross profit, and that, after deducting working expenses, &c., only a very much smaller sum remains as net profit. We are making further inquiries into the subject.—*Chemist and Druggist*, Aug. 30.

FOR OWNERS OF STEAM BOILERS.—It appears that the eucalyptus tree, besides its virtues as a dispellant of the malignant atmosphere in malarious localities, has another useful property which may be worth the attention of users of steam. From the report on the Lucknow Horticultural Gardens just published, we observe that a decoction of the leaves has been found efficacious as a remedy for the incrustation of boilers. Experiments have been tried in England with excellent results, the method of application being as follows:—"A large tank is filled with leaves and small branches, then the water is put in and boiled or made warm by waste steam. This continues till the fluid has a dark colour, when it is used; say two or three gallons of the decoction is put into the tender and so mixes with the water or enters the boiler with the feed." The matter is now engaging the attention of the Locomotive Department of the Bengal and North-Western Railway at Gorakhpur, and it is stated the trials made there have also shown good results. Apparently, however, the application does not prevent the formation of scale, but causes it to come readily off the plates when the boilers are being washed out.—*Pioneer*.

TEA-DRINKING IN ENGLAND.—Mr. Philip Gilbert Hamerton, in his recently published book, "French and English: A Comparison," thus refers to the English habit of tea-drinking:—

Another great change of custom in England, separating her from France, is of quite modern introduction. There was a time when both countries were total abstainers from tea-drinking, and, so far, exactly alike; now England is a great tea-drinking country and France is not. Here is a new subject on which they are not in sympathy. It may seem a trifle; but has the reader ever observed Englishwomen in France deprived of tea or supplied with the beverage in a weaker condition than they like? At such times they have a very low opinion of Gallic civilisation. Far-seeing Englishwomen who are accustomed to the continent take their own teapots with their private supplies, and make the indispensable decoction themselves. When drinking if they feel like Christians in a pagan land. Is that nothing? Does it not produce a perceptible sense of estrangement from the French? Tea-drinking has now become one of those immensely important customs, like smoking and coffee in the East, that have connected themselves with the amenities of human intercourse, and to brew your cup in the solitude of a foreign hotel is to feel yourself an alien. Yet how long is it since the English began to drink tea? They began tasting it experimentally, as a few Englishmen now smoke hashish, about the middle of the seventeenth century. Compared with ale and wine, it is a novelty. The greatest of Englishwomen, Queen Elizabeth, who was of English blood by father and mother, and thoroughly national, never drank a cup of tea in her life and did her work energetically without it. The use of tea has produced a special meal in the English middle classes which is unknown in France as it was unknown in England two hundred years ago. The French way of living, under other names, bears near resemblance to old English habits. The *déjeuner à la fourchette* is the early dinner, the *dinner* is the supper. The French first breakfast is modern, when *café au lait* is taken, but great numbers of French people take soup or a glass of white wine with a crust of bread, and many take nothing at all. Breakfast and tea are the peculiarly English meals, and they are modern. The one great English innovation which the French have never been able to accept is that of eating salty and greasy food, such as fried bacon, and drinking hot and sweet tea or coffee at the same time.

LOCAL MANUFACTURE OF CEMENT.—In continuation of the remarks formerly made by Mr. John Hughes to me with reference to the possible economical manufacture of cement in tropical countries, that gentleman has further informed me that, during a recent visit paid to the borders of Wales, he obtained specimens of the mortar of some of the more ancient of the Welsh castles, and that he had compared them with some of that obtained by him—from yourselves, I rather think—from the ancient dams which exist so largely throughout Ceylon. The result of his comparison of both was to convince him that in neither case was the mortar used of any artificial composition, such as are our English manufactured cements. It appeared certain to him that in both instances the lime used had been burned from limestone only, though of a very superior character, and that much of the exceptional hardness the specimens he had obtained possessed had been due mainly to the full vitrification resulting during centuries of time. It is more than doubtful, Mr. Hughes thinks, if any artificial process can ever succeed in rivalling the hardness attained as the result of such long periods of slow vitrification due to atmospheric and other influences.—*London Cor.*

ALLEGED EXISTENCE OF RICH GOLD MINES IN PAHANG, MALAY PENINSULA.—The *Indian Agriculturist* states:—An Australian digger named Sefton visited among other places, the State of Pahang, and there saw the natives engaged in alluvial digging with the most primitive appliances, which, however, yielded them vast quantities of gold. He wondered where all the gold came from, and after a careful search traced it up to Raub, where he avers is situated by far the richest mine in the world. He describes the mine "as an immense slate dyke increased in all directions with quartz veins from an inch in thickness to the diameter of a fine thread, and showing gold throughout freely. He followed this dyke for miles in places tracing the gold in lines along the surface for several yards at a time. Its breadth he could not possibly determine, but in places thought it might be measured by hundreds of feet." Sefton then interviewed the Raja who said that there was plenty of gold a little below the surface. The stone was too hard to work with the native hoe, and the Malays were content with what they found which was more than sufficient for their wants. It would seem that these people were almost as simple in regard to the value of gold as the people of America when first visited by the Spaniard. We are told that at Sefton's request "the Raja supplied men to get out about a ton of stone. This was taken from one of the seams pointed out by Sefton and was dollied up in a shallow wooden block with a bamboo pole shod with iron. The result was 102 oz. of gold, and Sefton declares there was almost as much more left in the coarsely pounded refuse. This gold Sefton sold in Singapore at £4-2s per ounce and sent the dollars back to the Raja." In Sandhurst and Ballarat in Victoria, there are mines that pay fair dividends on 8 penny-weights to the ton, and the surprise of the adventurous Australian can easily be imagined at obtaining 102 oz of gold from the ton by the roughest appliances, and gold worth not the regulation price of £3-17-6 per oz. but £4-2s which, we believe, is the second highest price ever paid. The result of the discovery has been the formation of a syndicate, composed, as we are informed, of some leading Australians, and eight Cabinet Ministers, and we presume Sefton and his adventurous colleagues. They have acquired twenty square miles of gold bearing country, embracing a lode six miles in length, the price paid for the concession being £320,000, of which £10,600 is in cash, and the balance in shares. The reports of the richness of this mine, and the discovery of rich auriferous country in Borneo have naturally attracted the attention of speculators to those regions, which are expected to yield wealth surpassing the dreams of avarice.

TOBACCO.—The damage—to the tobacco crop by reason of excessively wet weather varies from 15 to 25 per cent.—*American Grocer.*

PEPPER AT THE STRAITS.—In the course of the annual Reports on Lower Perak and Batang which give a good deal of information on planting with different products—which will all be republished in the *Tropical Agriculturist*—we have the following reference of special local interest:—

The pepper planted by Haji Ali in June, 1886, is now very fine, and is loaded with fruit. That planted last year by him and others is also doing very well. I find that pepper planted against dead wood posts is far finer than that planted against living deadap trees. In every place where the two supports have been tried together the result is the same. It appears as if the roots of the deadap rob the pepper of moisture nourishment. But the "dead posts" used in the Straits are of teak?

THE CINNAMON TRADE OF CEYLON.—The present condition of the cultivation of and trade in cinnamon is discussed in a recent issue of the *Ceylon Observer* of Colombo. In the days of the Dutch monopoly the Ceylon cinnamon, by far the finest in the world, first-rate bark was sold at a pound sterling for a pound in weight and as late as 1830 the average price of Ceylon cinnamon in the London market was as high as 8s per lb. But with the abolition of the monopoly and the consequent enormous increase in the export the price has fallen, so that the price last year was only 1s 3d per lb. In the monopoly days the average export from Ceylon rarely exceeded half a million pounds; but with the removal of restriction the exports rose to about three million pounds. This included not only the baled spice, but also "chips" previously worked up in the distillation of cinnamon oil. The large proportion of these chips introduced into the market at last reduced the splendid Ceylon cinnamon to the level of a competitor with the Chinese bark known as cassia lignea. A combination a few years to restrict the export of chips failed; but a new one is being formed for the purpose. Growers have been driven to take this step by the constantly falling price, which was recently down to 9d. Cinnamon bark is used to flavour chocolate and puddings, it is an ingredient in the incense used in some religious buildings, and is a constituent of some patent food for cattle. In medicine and confectionery the bark and essential oil are used to some extent, while it is combined with sulphur in a new mode of preserving meat. Except, perhaps, in this last direction, there is no prospect of increased consumption of the famous and once costly Ceylon spice. In some parts of Ceylon, especially in the well-known cinnamon groves near Colombo, the shrub is being cleared away to make room for the coconut. Besides pledging themselves not to trade in chips the leading planters agree also not to manufacture cinnamon-leaf oil, in the interest of the fine aromatic oil distilled from the cinnamon bark, chips being the residue. The two oils are wholly different in quality and taste, yet attempts have been made to adulterate the bark oil with that from the leaf. The latter somewhat resembles clove oil, and is employed to rub inside the covers of books as a preservative against fungi and insects. It would seem almost impossible to adulterate the bark oil, with its peculiar and delicate flavour, with the leaf oil, for the coarse and pungent odour of the brittle leaves of the cinnamon tree as compared with the delicate aroma of the bark, and its oil is one of the peculiarities of the plant; yet when one sees the delicate citronella and lemon grass oil of Ceylon adulterated with such a substance as kerosene one is prepared for any kind of adulteration. The Gingalese prepare from the roots of the cinnamon a substance like camphor, which is made into oandles for festive occasions. The bark of the cassia plants of China is greatly inferior to the Ceylon cinnamon, but the leaves have a pleasanter scent; this China cassia is supposed to be the cinnamon of the Mosaic and other ancient writings. However this may be, the Ceylon cinnamon, once so famous and so valuable, has fallen upon evil days, and now, like the silver in Solomon's time, is "little accounted of."—*London Times.*

SUGAR PLANTERS in the West Indies are anxious that the leading engineering firms at home should give more attention to improved machinery for sugar. Says the *Demerara Argosy*, after referring to an Australian and quadruple effect, worked on the novel principle that the vapour from the first effect will be found sufficient to vaporate the liquid in three other effects, and in two vacuum pans: "It is said that so great is the manufacturer's faith in this scheme, that he has supplied the machinery free of cost at first—payment to be made out of saving of fuel in its working. Why cannot English and Scotch makers show the same courage and enterprise?"—*Home and Colonial Mail.*

CEYLON TEA "DAGODA BRAND."—We have had the opportunity of trying a sample packet of this tea of the quality supplied to Penang (where Chinese are among the principal customers) and can speak of it in high terms. The brand is likely to become one of the best known over the world of Ceylon teas: besides Agencies in the Straits and United Kingdom, we learn that the enterprising proprietor is about to establish agencies in Baltimore and Washington, United States, where he will serve a large population, the higher classes of whom are ambitious of following European fashion and "afternoon tea" as in Paris should become universal. We trust there will be a big demand for "Dagoda" packets.

RECORDS OF THE GEOLOGICAL SURVEY OF INDIA.—Vol. XXII, Part 2. 1889. Contents:—Note on Indian Steatite, compiled by F. R. Mallet, Superintendent, Geological Survey of India.—Distorted pebbles in the Siwalik conglomerate; by C. S. Middlemiss, B. A., Assistant Superintendent, Geological Survey of India. (With one plate).—"The Carboniferous Glacial Period." Further note by Dr. W. Waagen, on a letter from Mr. O. Derby, concerning traces of a Carboniferous Glacial Period in S. America. Translated by E. O. Cotes, Assistant Superintendent, Indian Museum.—Notes on Dr. W. Waagen's "Carboniferous Glacial Period," by A. B. Wynne, F.G.S., and Dr. Ottokar Feistmantel.—Report on the Oil-Fields of Twingoung and Beme, Burma; by Fritz Noetting, Ph. D., Palaeontologist, Geological Survey of India (With one plate and a map). The gypsum of the Nehal Nadi, Kumaun; by C. S. Middlemiss B.A., assistant superintendent, Geological Survey of India. (With a plate).—On some of the Materials for pottery obtainable in the neighbourhood of Jabalpur, and of Umaria; by F. R. Mallet, Superintendent, Geological Survey of India.

COFFEE is considered, by Messrs. I. A. Rucker & Bencraft, to be in a sound position, and promises to be a rising article. The following are a few of the reasons why coffee must advance:—

(a). All over the world the trade is more or less scantily supplied, a hard to mouth policy being the fashion. (b). The visible supply is moderate, and promises to be much smaller. (c). The visible supply is on a scale which no longer allows us to compare statistics and values with the years of over-production, but on the contrary, with the years of under-production. (d). The current crops in the Brazils are turning out smaller than was anticipated. (e). The abnormal drought all over the coffee growing districts of South America precludes any hope of large crops for next season, no matter even if the blossoms be favourable. (f). The great danger ahead is that after abnormal drought we may suffer from excessive tropical rain, and that the blossoms on impoverished trees may be damaged and washed away. (g). In the North of South America, where the same sort of drought has been current, the crops which are some months ahead of the Brazil crops, are more or less very badly damaged, as regards quantity. (h). The statistical value based on the visible supply is only a few shillings below the current value, and we maintain that present rates shew little discount of the future.

MR. ROLAND TRIMEN ON "PHYLOXERA."

In going over an accumulated mass of papers recently, we came on a Cape Government notice to us by Dr. Trimen, which we annotated freely for publication, but which, with a vast number of other papers we were unable to overtake. Some portions of the paper may still be interesting. It is a report by Dr. Trimen's brother, Roland Trimen, F. L. S. &c., as Cape delegate to the Phylloxera Congress which assembled at Bordeaux in 1881. Mr. Thiselton Dyer and Mr. Trimen were the only English members. After preliminary matter, the report ran thus:—

The extremely animated discussion which ensued—especially on the bringing up of the Report of the Second Commission (that on the American Vines)—shewed very plainly that the French wine-growers for the present may be grouped in two grand divisions, viz.: (1) Those who still advocate the freeing of the European Vine from its enemy by the application of insecticides, and (2) Those who are strongly in favour of the more recent plan of restoring the vineyards by substituting American for European stocks.

It is convenient to mention here that neither party disputed the efficacy of the two other modes of treatment, under which it has been sufficiently proved that European Vines can be successfully cultivated in spite of the Phylloxera, viz.: 1st. Total *Submersion* of the Vineyard; and 2nd. Growing the Vines in ground consisting almost entirely of *Sand*. It is manifest, however, that neither plan is applicable to more than a few out of the great mass of vineyards.

As regards submersion, it has been clearly shown by experience that, in order to drown the Phylloxera, the entire vineyard must be kept continuously under water, of a depth not allowed to fall below eight inches, for a period of not less than forty-five days. For this purpose the vineyard has to be banked all round, and, after the requisite period has elapsed, the water is not drained off, but left to evaporate. In any case, the cost and trouble attendant on this operation must be considerable, but it is apparent how greatly they increase when, as in most cases, the water has to be lifted and pumped on the land. Unfortunately, too—owing to the powers of terrestrial and aerial progression possessed by the insect—the process of submersion has to be repeated every winter.

The growth of vines in pure sand and in soil extremely sandy—viz.: in which the proportion of sand is not less than 80 per cent.—has of late years considerably increased, and has led to the cultivation and consequent large increase in value of lands formerly waste and almost worthless. The immunity from Phylloxera which vines so grown enjoy appears to be due to the simple circumstance that the fine grains of sand, by their smoothness and want of cohesion *inter se*, hinder the subterranean progress of the insect, both along the line of the roots, and in its attempts to pass from one root to another. Large sandtracts close to the Mediterranean are now occupied by vines, and it is expected that similar districts in the Landes on the Atlantic seaboard will also be utilized as vineyards. The greatest objection to such localities is that they often contain an excess of salt in the sand, which is highly injurious to the vines.

In considering the strongly-advocated remedy by insecticide applications, it is impossible to fail in understanding and even sympathizing with the great reluctance with which the growers of choice and exquisite varieties of European vines—the result of the skill and laborious tendance of generations—regard the proposed abandonment of their direct cultivation, and with the ardent desire they manifest to maintain the old order of things at any cost. And it is quite clearly established, on the unimpeachable evidence of the first Commission, and of numerous men of mark and experience who spoke at the Congress, that the European

vine can, in spite of its mortal foe, be successfully maintained in its normal productiveness, by treatment with either bisulphide of carbon, or sulpho-carbonate of potassium, combined with a careful and regular supply of properly-composed manures. But it is equally certain that this method of overcoming the Phylloxera is very costly, especially if sulpho-carbonate of potassium be employed; and the cheaper of the two substances—bisulphide of carbon—injuriouly affects the vines, if the dose be not most carefully measured, or if it be applied in very wet weather, or in humid ground with an impermeable subsoil. The Commission declared, and it was not disputed, that it was absolutely necessary to repeat the treatment *every year*; and the more costly sulpho-carbonate was recommended for general use on the grounds of its being quite innocuous to the vines, and more speedily effecting their recovery. The carefully estimated annual cost of the combined insecticide and manure was stated by the Commission to be as follows, viz.:—

For the first year:—Bisulphide of Carbon, per hectare (nearly 2½ acres), 450 fr. (£18); Sulpho-Carbonate of Potassium, per hectare, 700 fr. (£28.)

For subsequent years:—Bisulphide of Carbon, per hectare, 300 fr. (£12); Sulpho-Carbonate of Potassium, per hectare, 500 fr. (£20.)

It is obvious that such expenses as these, however willingly borne by the great proprietors of world-famed vintages, are absolutely out of the question in reference to the mass of vineyards producing the bulk of ordinary wines; and it is thus no matter of surprise that throughout the Departments ravaged and in parts even desolated by the Phylloxera the only alternative generally applicable has been eagerly resorted to, viz.:—The replanting of the destroyed vineyards with vines whose roots more or less completely withstand the insect's attacks—these being the actual American species of the genus *Vitis* to which the Phylloxera is attached in its native country, and upon some of which it was originally introduced into Europe!

The cultivation in France of the American Vines, either as direct producers or as stocks bearing grafts of European varieties, has thus of late years been carried on with much vigour and with unquestionable success. It is not pretended that all American species and varieties exhibit equal powers of resistance to the foe—the observations and experiments of Riley, Planchon, Millardet, and many others, show that the contrary is undoubtedly the case: but, whereas neither in America nor in Europe has any European variety growing on its own root withstood the assaults of the Phylloxera, it has been satisfactorily proved (1) that all the American varieties resist in varying degrees; (2), that some—such as *Vitis Riparia* (=var. *V. cordifolia* apud Planchon), and the variety of *V. labrusca* known has "York's Madeira"—are to all practical purposes altogether uninjured by the insect; and (3) that—as Professor Planchon himself observed in addressing the Congress—the weakest of the American varieties has very much greater powers of resistance than the strongest European one. It cannot be doubted that this immunity, greater or less, of the American forms is simply due (as in a thousand similar cases to their having been obliged for innumerable generations to resist the insect's assaults in their native woods and that the balance between plant and insect has been so far struck that both contrive to flourish. Of course, both the vine and its parasite have numerous other enemies to contend with, so that the relation between them forms only a part of that complicated struggle for existence in which, like all other organisms they have to engage; but it is that part of their life conditions with which the viticultor is concerned, and he may thankfully accept the happy result. Some millions of cuttings of American Vines have been planted in France, in tracts where the Phylloxera had absolutely destroyed the European varieties; and the yield of wine both directly from their own grapes and from European grafts borne on their stocks has surpassed expectation. The facts and arguments adduced in favour of this mode of restoring the more than half ruined viticulture of France seemed

to me to be of indisputable force,—particularly as regards the all-important consideration of expense; seeing that the cost, admittedly considerable, of re-planting a vineyard is done once for all, whereas treatment by insecticides is an operation requiring annual renewal without assignable limit.

The Commission reported favourably on the wine produced directly from American vines, grown in large areas in the more Southern Departments, particularly commending those yielded by the two varieties of *Vitis cestivalis*, called "Jacquez" and "Herbemont," and expressed the anticipation that they would replace, to a considerable extent, the coarser descriptions of *vin ordinaire* and *vin du midi*. In company with Mr. Thiselton Dyer, I on several occasions tasted the two wines named (as well as others of similar derivation), and we agreed that both were extremely harsh and unpalatable—suggesting the mixed flavours of vinegar and mulberry juice—though concurring with the Commission so far, that, of the two, the Herbemont was preferable. Doubtless, however, wine of this rough type, however distasteful to a cultivated palate, will not be unacceptable in a country where the poorest peasants, and even their children, use wine as their habitual drink, and it will at any rate be infinitely preferable to the watered and otherwise adulterated fluids with which it has of late become the practice to endeavour to supply the great and unceasing demand for ordinary wine.

More interest, however, attaches to the American vines as the bearers of European grafts, for everything points to the conclusion that it is by their use as stocks that most of the better classes of wines will in future be preserved to us. All the evidence collected goes to shew that for this purpose the kinds above mentioned, viz., the varieties of *V. riparia* known as "Clinton," "Concord," etc., and the variety of *V. labrusca*, called "York's Madeira," are best adapted, alike for vigour of growth and practical indemnity from Phylloxera. It is important to observe, in relation to this particular subject, that the growth of seedlings of the wild species of American vines—initiated by Professor Millardet, in 1874—has now been shown to be far superior in its results to planting cuttings of the cultivated varieties of those vines. It appears that the desired qualities are so largely characteristic of young plants grown from seed of the wild vines in question, owing to their root-system being so much more fully developed, that it is worth the grower's while to wait the additional twelve months (three years being necessary for seedlings as against two years for cuttings) before grafting is effected.

Another mode of securing vines of good quality and power of resistance, which originated in America, is that of crossing the European and American species. The Commission reported that the results in America had been favourable as far as they had gone: while in France the red hybrid "Othello," and the white hybrid "Elvira," were especially mentioned as having been cultivated with success on a considerable scale. The latter hybrid was described as yielding a good wine, well adapted for the production of brandy.

I availed myself, with much satisfaction, of the opportunity of becoming acquainted with the living Phylloxera, and of noting the effects of its attacks on the roots and fine rootlets of the vine. It is true that the admirably accurate descriptions and figures published by the French entomologists, and especially those given by Dr. Maxime Cornu, in the well-known "*Etudes*," printed by the Academy of Sciences, would amply suffice, to any one conversant with insects, for identifying the destroyer; but nevertheless it is an undeniable advantage to have examined the insect itself, on its food plant, as the best possible descriptions, and figures fail to give the same exact impression as that which is derived from actual inspection of the living examples.

I had hoped to have met Dr. Cornu at the Congress, but was disappointed as attendance at the Berne Phylloxera Conference rendered his absence unavoidable. I had, however, the good fortune to make the personal acquaintance of M. Lichtenstein and Professor Planchon, both highly distinguished savans, whose

researches in connection with Phylloxera have been of the greatest value. M. Lichtenstein has specially devoted himself to tracing the extraordinary life-history of the insect through all its stages,—an arduous task for which his studies of the allied species of Phylloxera and of other Aphides, rendered him specially qualified. Professor Planchon in 1873 visited the United States, and made a thorough investigation of the indigenous vines (wild and cultivated), and of the Phylloxera in its native home; and he completely confirmed Professor Riley's view (also founded on an examination of the insect, both in America and France) of the absolute identity of the European ravager with the American species. The publications of M. M. Planchon and Lichtenstein have been of the utmost importance, contributing most effectually to the establishment of the successful methods of withstanding the Phylloxera, which are now in general use.

I was desirous of obtaining the opinions of these authors, so especially conversant with the Phylloxera in every point of view, as to the necessity of the extremely stringent regulations by which, with the view of preventing the introduction of the insect, all living plants, tubers, roots, bulbs, etc. were prohibited from importation at the Cape. I accordingly took the opportunity, in the course of conversation, of stating how matters stood. I found these gentlemen somewhat incredulous as to the condemnation of orchids from Rio de Janeiro, ferns from New Zealand, and other like instances, well-known here; but when I mentioned that such articles as moss and peat had also been seized, they found it so difficult to suppose that I was not exaggerating, or, at any rate, mistaken, that I felt glad to have Mr. Thiselton Dyer (whose recent shipment of peat from Kew was one of the seized consignments) at hand to sustain my credit! Being acquainted with M. Lichtenstein's observations as to the power of Phylloxera and other Aphides of resisting great cold, I inquired his opinion as to their ability to withstand a high degree of heat. He said that he considered it most probable that the insect would survive great heat. I then put the case of the possibility of the stray Phylloxera (or the winter egg) imagined by Dr. Cornu, in his reports to the Cape Government, as possibly being introduced on ship-board, although their only food-plant, the vine, were wholly absent; and asked whether during the unwonted stimulus of a high temperature, which, for a fortnight at least, the voyage to the Cape would involve, the insect's need of food would not naturally be increased, and the total absence of that food lead to its speedy decease. M. Lichtenstein admitted that he had not hitherto had occasion to consider the question of the over-ocean transport of the insect, under the conditions I had pointed out, and also that he thought the passage through the Tropics materially affected the question; but he was not prepared to pronounce any decided opinion. On the whole question, he thought that moderate restrictive measures were very desirable.

I discussed the same matters with Professor Planchon, who most kindly agreed to give me his written opinion, in response to a memorandum with which I furnished him. This he subsequently sent me from Montpellier, authorising me to make whatever use of it I deemed desirable; and I have much pleasure in appending a copy to this report. [Marked A. (Translation); dated 27th October, 1881.] It will be observed that Prof. Planchon, while fully approving of the exclusion of vines, is distinctly opposed to our shutting out other plants; pointing out, indeed that the Phylloxera is so strictly confined to the species of the true genus *Vitis*, that it may be deemed an excess of precaution to prohibit the introduction of the whole vine family (*Ampelidee*). But he recommends, as a practical method of avoiding what risk there may possibly attach to the admission of living plants, other than the vine, that with each consignment of this nature should be required a certificate, giving the locality whence the plants were derived, and showing that they are not brought from a phylloxerized region. And as regards the United Kingdom, where the

graperies are known to be in some parts infested, he further recommends that the Certificate should declare that the plants concerned have either been grown in the open air, or in green-houses or hot-houses not occupied by vines, and in both cases that cultivation took place away from the immediate neighbourhood of any vine. M. Planchon, in connection with this latter proposal, explained to me that he recognised a distinct risk in importing rooted plants in soil which had been taken up in the immediate vicinity of vines, in countries where the Phylloxera prevails; as, in the operation of removing such plants, some rootlets of the vine harbouring the insect might be detached with the earth, and could well maintain by the juices still in them a company of the Phylloxera for longer than the time of an ordinary voyage.

It will be noticed that Professor Planchon does not express any opinion on the point which I submitted respecting the possibility of the insect's surviving a voyage through the high temperature of the tropics in the absence of its only food, the vine. He writes to me to say that he refrained from noticing this, because he is not yet fully satisfied as to the length of time during which the Phylloxera can exist without nourishment. Dr. Cornu, however, stated so unreservedly. (Third Report to the Cape Government, paragr. IV), that "the insects, when removed in a living state, without vine roots, will die at the end of five days,"—that I have been accustomed to consider this limited period of withstanding starvation as an ascertained fact concerning the Phylloxera. If the period be of uncertain duration (and it is well known that some insects and other of the lower animals have maintained their vitality for months, and even years, without food), undoubtedly the opportunities of the Phylloxera's dissemination by chance means of transport must be very numerous; and we might almost despair of escaping its invasion, even at this distance from its seats of development. It must, however, be remembered that the case of an insect specially secluded to test its power of sustaining want of food, is widely different from that of one exposed to every vicissitude of ordinary out-door existence. And it is well worth remarking that the freedom of this Colony from invasion, notwithstanding its great and increasing traffic with Europe, distinctly militates against the belief that the Phylloxera possesses special fasting powers which would facilitate its dispersal over the globe. In fact, when one considers that up to November, 1876, there was no restriction on the introduction of vines themselves, while from as far back as 1863, the vineyards of France and the grape-houses in England had been infested, it certainly does appear that the dreaded insect is not so easy of ocean transport as some writers would have us believe, or surely it would have arrived in Table Bay during those thirteen years when its very food-plant was permitted free importation.

At the same time, I am entirely in favour of reasonable precautionary measures, and I think that those which Professor Planchon recommends are fully sufficient. The total exclusion of all vines should be maintained; the admission of all other plants from countries where Phylloxera of the vine does not exist should be allowed; and the admission of plants other than vines from phylloxerized regions (North America, Europe, and possibly Victoria, in Australia*) should be conditional on satisfactory certification that they have not been grown in the immediate vicinity of vines.

* I recently had occasion, as one of a Committee of Council of the Entomological Society of London, to report for the Secretary of State for the Colonies on the evidence forwarded from Victoria regarding the supposed existence of Phylloxera in that Colony. No specimens of rootlets or of insects accompanied the documents, and the Committee was unanimous in the opinion that the presence of Phylloxera in Victoria was far from being established. [But in 1880-81 the vines in Geelong district were being destroyed in consequence of the undoubted existence on them of the pest.—ED.]

I would most strongly urge upon the Government the propriety and expediency of relaxing the unnecessary stringency of the existing regulations in the direction, and, if practicable, to the extent which I have indicated. The attempt to enforce rigorously the sweeping provisions of the Proclamation issued has landed us in the absurdity of not only confiscating valuable and beautiful plants from regions where the vine and its attendant Phylloxera do not exist, but even seizing such substances of vegetable origin as dried moss and peat! It is certainly highly desirable that the Colony should lose no time in clearing its name and reputation for good sense from all further association with transactions so unquestionably foolish as these.

In this Report, I have not touched upon the *Mildew* and *Anthracoïse*, which have of late been introduced from America, and done much damage to the vines in France, because, although they were discussed during the Congress, both are vegetable parasites, and have of course no relation whatever to the Phylloxera. But I may mention that both Professors Millardet and Planchon, who have given much attention to these assailants, described them as occasioning very serious loss; M. Millardet even seeming inclined to prognosticate that their ravages might ere long prove as disastrous as those of Phylloxera itself.

In conclusion, I desire to express my recognition of the honour which the Government conferred upon me in appointing me its representative at the Bordeaux Congress. I need not say that I went as a learner only, having happily no experience of Phylloxera at the Cape to contribute to the melancholy records laid before the Assembly. But it was satisfactory to be able to assure numerous inquirers that there was no Phylloxera in the Colony, notwithstanding that the receipt of that assurance appeared in almost every instance at once to divest South Africa of any interest whatever to the inquirer. In fact there was but one absorbing subject in everybody's mind—the Phylloxera, and the Phylloxera only.

How and to what extent have you suffered from it? What remedies did you employ? What were the results? These three questions covered the whole ground, and any personal experience answering them was listened to with eager interest.

I was not, however, at all sorry to be, by force of circumstances, a little removed from participation in the actual bustle and restless activities of the Congress. Having no pet remedy to advocate, no pet aversion to condemn, no accusations to prefer against my neighbours, the Conseil-Général of the Department, the Agricultural and Horticultural Societies, or the Government; possessing, moreover, no desire to discomfit any adversary amid the plaudits of the assembly; I was all the more free to observe and to listen, and the better able to collect all the valuable information available. I have endeavoured in this communication to give that information in as condensed and succinct a form as possible, feeling it to be quite unnecessary (in the fortunate absence of the Phylloxera) to enter into minutæ which can readily be ascertained by reference to the numerous excellent publications on the subject. I have applied to the President for a copy of the *Compte Rendu* of the Congress, the preparation of which for the press was to commence in October last; and, pending its arrival, I beg to forward, for your information, several (10) publications which I procured at Bordeaux. The more important of the latter are the following, viz:—

"Grande Culture de la Vigne Américaine en France."
By the Duchess of Fitz-James. 1881.

"Notes sur les Vignes Américaines, etc." By A. Millardet.

"Le Phylloxera." By P. Mouillefert. 1875.

"Nouvelles Instructions Théoriques et Pratiques pour l'Application du Sulfo-carbonate de Potassium aux Vignes Phylloxérées." By P. Mouillefert. 1881.

"De la Reconstitution et du Greffage des Vignes."
By Madame Ponsot. 1880.

TEA, COFFEE, CINCHONA AND COCOA.

The report of the Commissioners of Her Majesty's Customs for the year ending March 31st, which have just been issued, prove unmistakably the extraordinary development of the home trade in Indian and Ceylon tea. A table which accompanies the report illustrates by some remarkable figures the continued decline of the British tea trade with China and the corresponding advance of that with India and Ceylon. In fact the tea trade with our two Eastern dependencies last year, for the first time, actually exceeded in amount the trade with China. The Commissioners do not conceal their regret at this fact, because they admit that it affects the revenue in a way they do not like. The Customs receipts from the tea duty would, undoubtedly, be much greater than they are if the home supply came exclusively from China, for the simple reason that Indian tea goes farther than that of China. The Commissioners declare that they make a moderate estimate in assuming that Indian tea "goes half as far again as Chinese tea" as regards depth of colour and fullness of flavour. That is to say, if one pound of Chinese tea produces five gallons of drinkable liquor, one pound of Indian tea will produce seven and a half gallons. The Commissioners add that if all the tea consumed in the United Kingdom last year had come from China, instead of partly from that country and partly from India and Ceylon, the customs receipts from this source of revenue would have been a million and fifty-four thousand more than it was. It appears to the Commissioners, therefore, that the displacement of Chinese tea by that produced in India and Ceylon is practically tantamount to a reduction of duty on the latter, the effect of which is differential in their favour as against tea from China.

The report referred to shows that coffee and chicory are gradually going out of favour, and are being superseded by cocoa. Notwithstanding the enormous increase in the population of the United Kingdom during the last ten years the customs receipts from coffee have declined by more than ten per cent. The receipts from chicory have diminished during the same period at a still greater rate. The customs duties upon cocoa, on the other hand, have largely increased. The yield of duty under this head last year was 9.19 per cent in excess of the record for the previous 12 months. The Commissioners attribute the satisfactory increase in the consumption of cocoa not only to larger production, and consequent lower prices, but also to the progress of the temperance movement.

Some letters have recently appeared in the *Dublin Daily Express* on the price of tea. One correspondent in a moment of weakness drew attention to the difference in quotation of the price of tea in Mincing Lane and that charged by the retailer in fair Dublin city. Thereupon an indignant tea merchant, who seems to be a lineal descendant of Dicken's Laurence Boythorne, writes:—"Your correspondent, 'H. J. L.,' pounces at random on an extract from some market report, without any knowledge whatever of its context. He, if the truth were known, was never near Mincing Lane in his life. He sees a quotation of 4½d for tea, and concludes that all tea is the same in quality and price. He emerges from the little narrow rat-hole of his own ideas into print, and concludes that 4½d per pound is the average trade price for good tea, and this, he infers, is sold by retailers at 3s per pound. He knows nothing about the Dooras and Darjeeling districts. The only knowledge that I can give him credit for is—that he knows the duty to be 6d per pound. Your correspondent, 'H. J. L.,' is not aware that the best

quality of teas only are negotiable in the Irish market, and if he chooses to call on me I will give him the names of a few houses in Dublin where he can get good tea if he wants it."

After generally anathematising the unfortunate "H. J. L." his opponent adds, "were your correspondent brought before the bar of my jurisdiction, I should unhesitatingly pass upon him my sentence (without power to appeal), namely, that he should be compelled to drink fourpence-halfpenny tea for the rest of his natural life." The punishment proposed seems out of proportion to the offence.—*Home and Colonial Mail*, Sept. 13th.

SUGAR, COFFEE AND CINCHONA IN NETHERLANDS INDIA.

In Java the sugar planters are at their wits' end how to cope with the disease which now works havoc among growing cane crops by cankering their roots. Plant cane from abroad has suggested itself as substitute from the home grown article now come under suspicion. Borneo at first came into favour as a supplier meeting requirements. To satisfy the demand, nurseries were laid out there, and looked promising enough at the outset. They have fallen into discredit, owing to the dreaded disease appearing there among the young cane. Celebes will now be tried, and commissioners have been sent there by Java sugar planters to see what can be done in that line. In Java the cane has suffered much from excessive rain, followed by a severe drought. Masses of dead cane, fit only for fuel, cumber the fields. The planters, for all that, count upon an abundant crop larger than that of last year.

The *Government Gazette* of Netherlands India contains an official report on coffee leaf disease there by Dr. Burck, a botanical specialist. As remedy, he recommends the planting of trees thickly around coffee plantations to stop the wind-borne germs of the disease. Sprinkling the leaves of coffee trees with tobacco water has been found useful as safeguard. That fluid has also done good service in nurseries.

In the Preanger Regencies in Java the cinchona planters have taken steps for combined action. They intend to start a cinchona syndicate with a view of controlling the output and regulating prices.—*Straits Times*, Sept. 30th.

TOBACCO:—NORTH BORNEO PLANTING NOTES.

A syndicate has leased the Tutong river in Brunei from the Sultan for 55 years. The area of agricultural waste land on the Tutong is estimated at 100,000 acres.

We hear the Tutong Syndicate intend to grow tobacco, but in view of the difficulty that exists of getting labour in this state and in Sarawak we wonder how the syndicate will obtain their coolies, for we are told that at present it is illegal to engage Contract labour either in Hongkong or in Singapore for service in Brunei.

At Mr. Van der Hoeven's estate, visited in the early part of the month, there was a grand display of tobacco plants; even and regular in height and as thick as they could grow; the leaves of extremely large size, the nerves small, and the texture of extraordinary thinness. Not only was one part of the estate like this, but field after field showed the same characteristics.

Cutting and carrying had commenced in earnest and by the end of the month Mr. Van der Hoeven hopes to have half his crop housed.

This tobacco burns with a very white ash, and its reception on the Amsterdam Market is looked forward to with much interest. A very high price is freely predicted for it.

The following is an extract from *The Hongkong Telegraph*—

The Lamag Planting Company, Limited, was registered here a few days ago with a capital of \$300,000 in six thousand shares of \$50 each, \$25 paid up. The property of this Company is situated near the Koyah estate in British North Borneo, and the general managers are Messrs. Gibb Livingston & Co., with the Hon. B. Layton and Messrs. H. L. Dalrymple and E. E. Abrahamson as a Consulting Committee. All the shares have been subscribed for, and a manager (an old Sumatra planter) has been appointed. The China-Borneo Company, Limited, are the local agents of the Company in Borneo.

Two new Tobacco Estates are being opened on the Kinabatangan, one by Mr. H. Stooft for the London Amsterdam Tobacco Company, Limited, and by Mr. Kortahy for the Sandakan Tobacco Company, Limited. We understand that other estates will shortly be opened on the same river.—*British North Borneo Herald*, Sept. 1st.

PLANTING IN THE WEST INDIES.

(By an ex-Ceylon Planter.)

Grenada, W. I., Aug. 30th.

This is a most fertile and beautiful island. The climate at sea-level is much like that of Colombo, and on the higher lands it is near perfection. Our staple product is cacao, but some attention is given to canes, and nutmegs have been planted on a fairly large scale.

The soil and climate are suitable for the cultivation of nearly anything; coffee, of which formerly there was a large acreage, gave way to cacao and can now only be seen here and there in small patches; and although little or no attention is given to it, the trees are laden with cherries, and there are no signs of your old enemy *Hemileia vastatrix*.

Tobacco cultivation has lately been reintroduced, (some 150 years ago it was the staple of the island), and will, with proper care, and planted at the right season, do splendidly; but it is absolutely necessary that we should have an expert to teach us the "tips" for us to succeed in making the enterprise a complete success.

Labour is good: a Creole will generally do a day's work for a day's pay 1s 2d to 1s 4d, they are willing and cheerful, and decidedly humorous. Cacao and other products grow luxuriantly to within a yard or two of the sea. The only enemy of any consequence to the cacao tree is the cacao beetle, this pest lays its eggs or spawn under the bark of the tree next to the cambium and unless these are removed and the beetles destroyed they are very destructive in "ringing" the trees.

A cricket club has been started in London for West Indians in England, and, as it will boast of several old "county" men, will be able to turn out an eleven worthy of the West. "West Indians v. Ceylon" would prove an attraction at Lords or the Oval.

AN OLD CEYLON PLANTER.

THE PROPOSED STRAITS PLANTERS ASSOCIATION.

With reference to a query addressed to us by the writer of "Johore Notes" asking about the proposal to start a "Straits Planters Association" we are glad to learn that preliminary steps are now being taken for this purpose. The annexed circular has been issued to a number of gentlemen who are interested in planting in the Native States and Johore. There is some talk of including British Borneo in the scheme, and even the Sumatra planting interest. While the former

suggestion may prove useful it is probable that the Deli people being under a different administration would not find themselves able to co-operate beyond certain limits. The big subject will no doubt be that of immigrant labour and here joint action will be of great benefit to the planting interest at large. This is the circular referred to which is issued by Mr. Edmund A. B. Brown, Honorary Secretary, Penang and Province Wellesley Planters Association.—*S. F. Press*, Sept. 11th.

HOW TO MAKE TEA PROPERLY.

Messrs. Brooke, Bond, and Co., tea dealers, answer the enquiry of the *Daily Telegraph*, by giving the following receipt for making tea on scientific principles. The water to be used should boil, and it should be poured on the tea immediately it boils; if allowed to overboil the peculiar property of boiling water which acts upon tea evaporates, and eventually disappears. As to the precise number of minutes which should be devoted to the process of drawing, experience is in favour of six; this suffices to bring out the flavour, quality and strength. Just as much tea as it wanted should be made—no more. Make fresh tea as often as is required. The teapot should be made thoroughly hot before the tea is put in it. Tea readily takes up the smell of coffee, cocoa, spices, cheese, bacon, or other articles of pronounced odour. The complaints sometimes made about tea would probably not arise if always kept in places free from such contagion. Tea should be stored in a warm dry place; unnecessary exposure to the air should be avoided. Even when securely packed in the leaded chests in which it arrives in England the change from the glowing heat of Eastern skies to the damp and humid atmosphere of this climate deprives tea of much of its beautiful-fragrance.—*H. & C. Mail*.

CEYLON TOBACCO IN LONDON.

We think the following report (placed at our disposal) on part of the Ceylon tobacco sold lately in London full of encouragement to Ceylon planters engaged in this cultivation to take pains and put in practice "the wrinkles" given them in "All About Tobacco":—

REPORT ON TOBACCO FROM HUNASGERIA ESTATE
Ex "ORIZABA" sold on Sept. 19th, 1889.

Bales.	Properties.	Sold at per lb
2	Part middling leafy; part short; part rather narrow; part thin and silky; part coarse and waxy; colors irregular; large part reddish; some veins rather coarse.....	10½d
3	Part middling leafy; part short; generally rather coarse in texture; and much mixed in color	6½d
2	Much mixed in size and color; part imperfect: part blistered; generally inferior...	4d
The fermentation of this tobacco appears to be incomplete.		

CACAO IN CEYLON.—We read but little of late in our Ceylon papers of any present or contemplated extension of Cacao Cultivation by your planters. This seems regrettable, and it is desirable to call your attention to a statement appearing in the market reports of *The Times* which mentions that "Ceylon cocoa, through its scarcity, has obtained much higher prices." This shows that your product is being much inquired for, and it would only seem judicious that every attempt should be made to produce supplies that will be adequate to this manifest demand. Sir William Robinson, the present Governor of Trinidad, told me recently that the reason why the cocoa grown in that island holds its own so strongly is that it is superior in the "fattiness" so dear to the hearts of continental cocoa drinkers to that produced elsewhere. On the other hand, Mr. Roberts has told me that the delicate flavour of Ceylon cocoa is more appreciated by the manufacture of sweet-meats. Could not both qualities be obtained by your planters?—*London Cor.*

TOBACCO CUTTING, HOUSING, CURING AND PREPARING TOBACCO FOR MARKET.

Harvesting begins early in July and continues without intermission to September. The time of day preferred for cutting is from 2 o'clock in the afternoon until nearly sundown, because at that time tobacco is less liable to be blistered by the heat of the sun. The instrument used for cutting is a hatchet, the plants being cut off nearly on a level with the ground and laid back on the rows to wilt. After wilting they are speared on laths. Of the large seed leaf varieties only about six plants are put on a lath, but of the smaller Spanish or Havana varieties ten are not considered too many. After being speared on the laths, the latter are carefully put on a long wagon frame made for the purpose and carried to the sheds, where they are arranged on the tier poles or racks from six to ten inches apart, according to the size of the plants, but never so close as to permit them to touch each other.

It requires six weeks to cure the Spanish varieties perfectly, and two weeks to cure the seed leaf. If the weather is dry after the crop is housed, the doors are kept closed during the day and opened at night, but extreme care must be taken not to cure too rapidly. In muggy, sultry weather, as much air as possible should be given; thorough ventilation being indispensable to prevent pole-sweat. Continuous damp weather or continuous dry weather are both to be feared. It is believed by many good growers that white veins are the result of a drouth after the tobacco has been harvested, and it is said that no crop cured when there's plenty of rain is ever affected with them. Inferences of this kind, however, are too often drawn without considering a sufficient number of cases to warrant the enunciation of a general law. It is a well established truth, however, deduced from the universal experience of the cultivator of seed leaf tobacco in every State, that a crop cannot be well cured without the alternations of moist and dry atmosphere.

From the 1st of September to the 1st of January is the usual period for preparing the crop for market. The usual practice among farmers is first to strip the leaves from the stalks, tying them up in large bundles and assorting afterward. A few assort directly from the stalk, but "table assorting" or assorting after stripping, is preferred by the most painstaking farmers. After the tobacco has been carefully assorted into three or four grades, generally first wrappers, second wrappers, fillers and binders, it is tied in "hands" of from eighteen to twenty leaves securely wrapped with a leaf at the butt end, and "bulked" or "banked" in piles, with the heads out and tails overlapping in the centre of the bulk. Here it remains until the fatty stems are thoroughly cured, when it is ready for market, unless the grower prefers to pack it in boxes himself. The selling goes on all the winter, and even up to May. In all the towns, and vilages of any considerable size in tobacco-growing regions there are established what are known as warehouses, where dealers buy, pack and sweat the crop, preparatory to offering it in the markets.—*Tobacco Plant.*

FERTILISERS FOR PLANTS.

For no one manure can the same amount of infallibility be asserted, for none can so universal an application be proclaimed as for So-and-So's cosmopolitan pills. Every gardener, too, knows, what the public appears not to realise in the case of physic, that a manure which may be excellent at one time or for one plant, may be useless or even injurious at another. Gardeners, too, are often made to pay an exorbitant price for an article otherwise good. This was made apparent some years since, when we published a series of analyses of popular manures and insecticides. All of these proved good in their way, but the prices charged were in most instances extremely high. Any village chemist capable of compounding a prescription for a cow can mix a preparation suitable

for plants under different circumstances, but as an aid to gardeners and others we cite the following from a recent number of the *Jardin*. They or something equivalent have often been cited before, but the proportions of the several ingredients have not always been stated in so convenient a fashion. Dr. Jeannel's prescription, containing, as it does, notable proportions of nitrogen, phosphoric acid, and potash is of general utility, though, indeed, the amount of potash in the soil is rarely deficient:—

Nitrate of ammonia	380 parts.
Biphosphate of ammonia	300 "
Nitrate of potash	260 "
Biphosphate of lime	50 "
Sulphate of iron	10 "

1000

For flowering plants in pots the following mixture is recommended:—

Superphosphate of lime	4 parts.
Sulphate of lime	2 "
Nitrate of soda	$\frac{1}{2}$ "
Sulphate of ammonia	$\frac{1}{2}$ "
Chloride of potassium	$\frac{1}{2}$ "

For foliage plants in beds:—

Superphosphate of lime	4 parts.
Nitrate of soda	3 "
Chloride of potassium	1 "
Sulphate of lime	1 "

300 grammes (say $\frac{1}{2}$ lb.) to be used per square yard at the time of planting. By citing it in this fashion the quantity to be made may be large or small. M. le Marquis de Paris recommends for foliage plants in pots:

Nitrate of soda	1 part.
Sulphate of ammonia	1 "
Superphosphate of lime	2 "
Sulphate of lime	" "
Chloride of potassium	$\frac{1}{2}$ "

For flowering plants in beds:—

Nitrate of soda	2 parts.
Superphosphate of lime	10 "
Chloride of potassium	2 "
Sulphate of lime	4 "

Of these mixtures a teaspoonful should be used in a gallon of water once a week.—*Gardeners' Chronicle.*

PALM KERNEL OIL.

We take the following from an investigation by E. Valenta, on palm kernel oil and its composition:—

The seeds of *Elaeis guineensis* and *Elaeis melanococca*, from the fruit flesh of which palm oil is obtained, contain the variously formed brown, often veined kernels, which through pressure or by extraction with solvents furnish the palm kernel oil which is largely employed in the manufacture of soaps. Formerly the seeds were not utilized; later on the negroes of the Mombattu Lands prepared an impure oily fat from them by breaking the shells and filling the kernels in earthen pots, which they buried in the earth and built a fire over them. In this way a part of the fat was tried out. Afterwards the seed were brought to Europe, where they were treated in numerous factories specially constructed for this purpose. The oil is obtained by grinding and pressing, or by extracting the meal of the palm kernels. The oil cakes, after pressing, still contain about 10 per cent. fat, but these are often subjected to some extraction process by which the fat remaining in the cake is reduced to 1 per cent. The de-oiled palm kernel meal contains considerable quantities of protein compounds, and the ash phosphoric acid and potash. The palm kernels, according to their origin, show a very varying percentage of oil; according to Schaedler, it varies from 40 to 62 per cent. But even in kernels from the same source variations in the percentage of oil are found. Several years ago Valenta examined two samples of so-called Sherbro kernels and found them to contain 43 to 48 per cent.

On account of the large quantities of albuminoids and vegetable gums which the crude palm oil contains, it is often subjected to a refining process, by which

a yellowish product is obtained, which when fresh has an agreeable odor, a lard-like consistency and behaves with alkalies, etc., very much like coconut oil, with which it also closely corresponds in composition. The melting point of palm kernel oil is given by Schaedler at 25° to 26° C., the density at 15° C. at 0.952. That the former is subject to great variations according to the age and origin of the fat is evident; palm kernel oils are therefore found which melt at 23° C., while others melt at 28° C.

For the determination of the fatty acids contained in palm kernel oil, several varieties of them (one of them pressed from Sherbro kernels in the laboratory) were saponified with soda lye of 38° B. with the addition of a small quantity of alcohol. After carefully evaporating the alcohol, the resulting soap was boiled on a reflux condenser with dilute sulphuric acid, until the fatty X-acid had perfectly separated. The fatty acid were then separated by means of a separatory funnel, and washed with luke-warm water, after which they were dried under an air pump, and the melting point, saponifying value and iodine number determined.

No.	Melting point °C.	Saponifying value in mgmt. of KOH.	Iodine value to Huebl in % of iodine.	Remarks regarding the origin of the fats used in preparing the fatty acids.
1.	25°	261	14	Fresh fat, pale yellow.
2.	26.5	258	17.5	Fresh fat, yellowish Brown.
3.	25.4	259	17	Fresh fat, chocolate brown obtained by pressing
4.	28.5	265	12.8	Very rancid, old fat, almost white.
5.	27°	261	10.3	Prepared in the laboratory, pale yellow.

—Oil, Paint and Drug Reporter.

THE AVERAGE YIELD OF PADDY—
A CHALLENGE!

I have read with the deepest interest the results of experiments in Paddy Cultivation in the model districts of Galle and Batticaloa, as reported by Messrs. Green and Elliott. I have myself been a practical agriculturist for many years past. Whatever the yield of a few bushels of paddy sown in a select spot may be, where hundreds or thousands of acres have to be taken into account, as at Batticaloa and some other districts, the average yield of paddy can never be more than 12 or 15 bushels per acre—it is indeed generally less than 10 bushels. It is the general opinion among Natives that these two Civilians are very public-spirited and philanthropic, but at the same very misguided gentlemen. I hope they are not.

But to settle the question of the average yield per acre once for all, I make the following proposal. Let the Editors of the four leading Newspapers in Colombo be the Umpires. There are four kinds of lands in Batticaloa, viz., (1) Rain-fed, (2) Stream-fed, (3) Village-tank-fed, (4) Government-tank-fed fields. I will offer from 25 to 50 acres of each of these descriptions of lands in different parts of Batticaloa amounting in the aggregate to 200 acres of excellent, good, bad and indifferent fields. My calculation based on actual yields for the last few years, is that the highest average yield of these 200 acres of typical fields can never be more than 10 or 12½ bushels per acre—as follows for the 200 acres in round numbers. Cost of cultivation 1500 B according to Mr. Elliott's own letter.

Title 250 B
Rent to land owner 750 B at only 3¼ bushels per acre.

Total 2,500 B

Now, if Messrs. Elliott and Green really mean what they say and have the courage of their opinion, I offer them the lands within easy access in the best typical parts of Batticaloa. Let them cultivate these according to their own methods, give the owner only his rent of 50 B, and take all the rest of their alleged enormous profit to pay the Government tithes and the cost of cultivation and to reward their men, or for any other purpose. I will be bound if at the end of their first year they do not rue their oversanguine generalizations. Pottering with two acres is quite different from manipulating 200. If, on the other hand they so desire it, I am ready to lease out these 200 acres to them or their agents for the next five years at this rental, and also have the cost of all permanent improvements made by them deducted from the rent.

Now, this is a fair experiment. Let these gentlemen or others of their opinion come forward and accept the challenge; or, in the presence of all Ceylon, let them keep silence for ever! Within five minutes of any one of the four Editors intimating to me that it has been accepted, I am ready to call at the office and take the necessary steps to hand over the lands for carrying on the experiment.

—Local Examiner.

A TAMIL CULTIVATOR.

PARING AND BURNING VS. FUMIGATION.

C. D. in his letter to the *Observer* vindicating the character and reputation of the Agricultural School—which by the way "Old Planter" did not asperse—speaks of the value of paring and burning on clayey and peaty soils. As far as my information and personal observation go, Nuwara Eliya is the only place in the Island where this operation is regularly and systematically carried on. It will be very interesting to find out whether the practice was introduced by Europeans, or whether the Native population of the plains took to it from observing how well plants grew on soil that was burnt. The soil of the plains as well as of the adjacent patanas is a black peat overlying water-worn gravel. From an excess of vegetable matter, the soil is almost sterile and inert, and is quickened into life only by paring and burning. I am surprised liming is not resorted to, for with limestone cropping up not far from the plains the price of lime cannot be prohibitive. Is it, I wonder, that the value of liming is unknown, or that paring and burning is the cheaper system of ameliorating the condition of the soil? In this connection, may I be permitted to repeat a suggestion I made before, of having an Agricultural Station in connection with the School of Agriculture at Nuwara Eliya? It can be under the supervision of an Instructor, and the pupils can migrate thither with their Superintendent during certain months of the year.

The resemblance between the operation of paring and burning, and the burning the soil receives in the process of fumigation is very slight. In stiff soils the effect of burning is very marked, especially in their texture. The soil becomes quite free and porous, almost sandy. I, however, think it is not prudent to burn light soils which have no body. Where the soil is occupied by coconut trees and plants, burning is possible only to a very small extent. Unless smother-fires are resorted to, the branches of the trees become scorched. To prevent too fierce fires, I burn branches and husk after the first rains that break up a drought have fallen, and before these materials have become quite dry and combustible. The residual ashes I spread and dig in. During the following season it is best to shift the sites of the fires, as otherwise the mass of rootlets that are feeding on the old sites will be destroyed and no benefit will follow burning. With fires well smothered with sods of earth, it will be possible to take them over a greater extent of ground than open fires.

Let us now consider by what means burning benefits a soil. The soil is a vast store-house of plant food. A wise Providence has ordained that but an infinitesimal portion of it should be in an active or soluble

state, *i. e.*, available as plant food. An authority gives from 1 to 3 per cent only as readily available! The rest of the soil is not valueless, it has plant in a dormant or insoluble form. The forces of nature are constantly at work in reducing the percentage of insoluble plant food in the soil. We aid these by breaking up the soil and affording an easy ingress into it of the carbonic acid and oxygen of the air, both gases being disintegrators, and the rain. The action of water in the soil is very great, more so in a stiff soil. The more water passes through a soil, the more aeration it receives, for where water passes through air must follow. Unfortunately this is not as well known as it should be. In discussing the value of trenching with a friend lately, I said the greatest good it did was to pass most of the rain that fell on the Estate through the soil and not over it. His reply, which was meant to be sarcastic, is extremely amusing, and displays the extent of his knowledge on Agriculture. "The idea can at least be claimed as original, and will no doubt be followed by all those who see its advantages"! If these ideas are not original, nothing is. To resume. Liming is an operation which tends to greatly accelerate the setting free of the insoluble mineral and organic portions of the soil going on continuously around us by means of natural agencies. Burning effects the same object almost instantaneously. But the action of fire is so quick, and the chemical combination which produces it is so intense, that where in liming the liberation of nitrogen is comparatively slow and is available to the roots of growing crops, in the process of burning it is liberated at once and wasted. But burning is a very valuable operation notwithstanding this drawback, especially on clay lands which are particularly rich in valuable mineral matter, chiefly potash in a dormant state. It must not be forgotten that the waste of nitrogen I spoke of takes place only where the action of the fire is felt, and as the whole surface of the ground of a Coconut Estate is not, and cannot be burned, at one time, the loss of nitrogen will not be great. The soil has locked within it vast stores of nitrogen carried into and fixed in it by the decay of vegetable and animal matter during many ages. From this source can be replaced what the fire has dissipated. This will be rendered more easy by the improved mechanical condition of the burnt soil permitting thorough aeration.—B.—Local "Examiner."

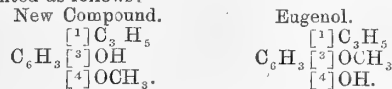

NOTES ON ESSENTIAL OILS FROM MESSRS SCHIMMEL AND CO.'S REPORT.

The following notes on various essential oils are taken from the April *Bericht* of Messrs. Schimmel and Co., of Dresden:—

Angelica Oil.—The results obtained from the parcel of angelica root imported from Japan, to which reference was made in the previous report (see before, p. 326), differ essentially from those experienced with the German drug. The Japanese roots have the same tufted-form as the German, but are lighter and nearly white and are provided with stronger rootlets. They are referred to one of two species, *Angelica refracta*, Fr. Schmidt (Jap. "*Senkiyu*"), or *A. anomala*, Lal. (Jap. "*Biyaokushi*"), both of which, according to Rein, are cultivated in the open fields in Japan. This Japan angelica root proved to be comparatively very poor in essential oil, the yield being only one-tenth per cent, the oil also being essentially different from commercial angelica oil. Whilst the German distillate has a specific gravity of 0.853 at 20° C. that of the Japanese is 0.912 at the same temperature. At 10° it gives a separation of crystals and at 0° it solidifies to a paste. The crystalline mass obtained by cooling and draining had the properties of a fatty acid melting at 62°-63° C. The oil boils between 170° and 310° C., the last portion that passes over having a beautiful blue-green colour. The residue solidifies upon cooling and consists principally of the non-volatile fatty acid. The odour of the oil is unusually intense and persistent, more acid than that of the German angelica oil, but possessing the characteristic suggestion of musk. The cost of this oil deprives it of any industrial importance.

Anise Oil.—The statement made on "high authority" in the paper read at a recent evening meeting of the Pharmaceutical Society by Mr. J. O. Umney, to the effect that for every pound of aniseed oil from *Pimpinella Anisum* a thousand pounds of star-anise oil are met with, and the subsequent statement of Mr. John Moss that he would put the proportion as one to ten thousand, are sharply criticized as underestimating the importance of the aniseed on industry. Messrs. Schimmel say that in their factory alone under ordinary circumstances 7000 kilos of aniseed are worked up daily, yielding 200 kilos of aniseed oil. They place the annual production of oil from seeds of *Pimpinella Anisum* at 42,000 kilos, or equal to about 1,400 canisters of star-anise oil, and they raise the question whether the annual production of star-anise oil amounts to 1,400 canisters, to say nothing of one thousand or ten thousand times that quantity. Messrs. Schimmel make this correction in the hope that in future such questions may be discussed "with more care and upon a better basis, bearing in mind that the centre of gravity of the manufacture of essential oils lies in Germany, and not in Engand."

Betel Oil.—A statement made in a previous report to the effect that the essential oil of betel leaves contained eugenol was considered to be opposed to a report by Professor Eykman upon the composition of a sample of betel oil examined by him; a fresh investigation has therefore been made with the following result. The sample of betel oil examined was a slightly brown coloured liquid, sp. gr. 1.024 at 15° C. It consisted up to about two-thirds or three-fourths of a phenol, the boiling-point of which in partial vacuum, under a pressure of 12 mm., lay at 131-132° C.; under ordinary atmospheric pressure it underwent decomposition on boiling. The specific gravity of the phenol was 1.067 at 15° C. Examination of the oxidation products, acetyl compound and methyl ether showed that this compound was not eugenol, but an isomer, the composition of the new compound and of eugenol being represented as follows:—

The second constituent of betel oil boiled practically between 250° and 275° C., had a very agreeable tea like odour, and consisted for the greater part of a sesquiterpene (C₁₅H₂₄), cubebene, which is characterized by its dihydrochlorate melting at 117-118° C. This composition differs considerably from that given by Professor Eykman, but how far the difference may depend upon the oil examined by Professor Eykman having been distilled from fresh leaves, whilst that examined by Messrs. Schimmel was distilled from dried leaves, has not been determined.

Bergamot Oil.—Some question having been raised recently as to the natural colour of bergamot oil, Messrs. Schimmel publish some information on the subject obtained from two of the largest producers in Reggio. One of them says:—This essence occurs for the most part of a brown-yellow colour. A certain quantity approximates more to green, but this is an essence prepared only from unripe fruit. In commerce it seldom occurs pure, since it is ordinarily mixed with the essence prepared later from ripe fruit. Carefully examined in a glass tube it cannot properly be called 'green,' but there is always a yellow colour perceptible. The emerald green essences which have been exported from Messina are such as have been allowed to stand for a long time in badly tinned vessels, and the colour is due to oxide of copper." The second correspondent says:—"After the working of the bergamot fruit the essence obtained is honey coloured, and it is usually put forward and sought for of this colour. The green colour is acquired when the oil is allowed to stand a certain time—about seven or eight months—in the vessels; it attacks the tinning and becomes green through contact with the copper. This is the correct explanation of the two colours; any other is false."

Cajuput Oil.—Referring to a large consignment from Macassar, Messrs. Schimmel state that according to

their experience cajeput oil directly imported is always genuine and trustworthy, but that in intervening commerce, and, as they hear, especially in America, it gets adulterated with camphor oil. On practical grounds an adulteration with eucalyptus oil is not to be feared, as that oil is more costly.

Calamus Oil.—Reporting on the Japanese calamus root referred to in the previous *Bericht* (see before, p. 326) it is stated that these roots do not differ externally from European calamus roots and are no doubt derived from the same species. They contain 5 per cent. of a highly aromatic essential oil, which is considerably heavier than the German calamus oil, having a specific gravity of 0.991 at 16° C. It boils between 210° and 290° C.; if the distillate be collected in two fractions, the lower portion has the characteristic calamus odour, while the higher boiling portion gives off the peculiar sesquiterpene odour. Japanese calamus oil also differs from the European in solubility, 1 part dissolving in 500 parts of 50 per cent. spirit, the German oil requiring 1000 parts of spirit.

Camphor Oil.—Under this name the light-boiling portion of the crude camphor oil appears to find enormously increasing industrial application as a substitute for turpentine oil. More detailed information is now given concerning its characters and composition. It is stated that after the preliminary runnings, smelling disagreeably of aldehydes and acids, the oil begins to boil at about 158° C. The first fraction, boiling between 158° and 162° C., consists of right-handed pinene, identified by the formation of the hydrochlorate, $C_{10}H_{16}HCl$, as well as of sitosoterpene, melting at 130°, obtained by treatment of pinene nitroschloride with alcoholic potash. In the portion boiling between 169° and 171° phellandrene was detected, but in very small quantity; it was identified by its nitrite, melting at 102°. Dipentene was found in camphor oil by Wallach, and the tetrabromide and nitrosylchloride compound may be easily obtained from the fraction boiling at 180°. The occurrence of terpineol in camphor oil has not been determined with certainty. Whilst the formation of a compound having the composition $C_{10}H_{16}2HI$, as well as of terpin hydrate, dipentene and terpineol, rendered its presence highly probable, it was, on the other hand, rendered doubtful by repeated failures to obtain the dipentene dihydrochlorate and tetrabromide. There is also in camphor oil a considerable quantity of a hydrocarbon, boiling about 260° to 270°, from which was obtained the hydrochloric acid compound, melting at 117°, characteristic of the sesquiterpene cubebene. In the highest boiling fractions of camphor oil occurs an intensely blue coloured oil, which is probably identical with the constituent, boiling at about the same temperature, occurring in chamomile, millefolium, wormwood and other oils. The constituents of camphor oil found up to the present are—

Boiling point.	Constituent.	Formula.
158°-162° ..	Pinene ..	$C_{10}H_{16}$.
170° ..	Phellandrene ..	$C_{10}H_{16}$.
176° ..	Cineol ..	$C_{10}H_{18}O$.
180° ..	Dipentene ..	$C_{10}H_{16}$.
204° ..	Camphor ..	$C_{10}H_{16}O$.
215°-218° ..	Terpineol ..	$C_{10}H_{17}O$.
232° ..	Safrol ..	$C_{10}H_{10}O^2$.
248° ..	Eugenol ..	$C_{10}H_{12}O^2$.
274° ..	Sesquiterpene..	$C_{15}H_{24}$.

Cananga Oil.—The opinion is expressed that the finer sorts of Java cananga oil can be used for all purposes for which the ordinary qualities of ylang-ylang oil suffice, since both oils are derived from the same plant and the extraordinary differences in quality are due to the more or less perfect methods of preparation.

Chamomile Oil.—In order to prevent as much as possible the original blue colour of this oil from changing to green it is recommended that it should be protected carefully from the influence of light and heat.

Citronelle Oil.—The exports of this oil from Ceylon during the year 1888 are estimated to have amounted to at least double the exports of the previous year, since in the month of August alone the shipments reached 2,322,890 ounces, or four times the

average of the same month in the three previous years. This enormous export from Ceylon is driving the production of the oil in the Straits Settlements into the background.—*Pharmaceutical Journal.*

ADVICE TO TOBACCO PLANTERS.

HOW THEY SHOULD CURE THEIR CROPS.—RECOMMENDED BY THE PETERSBURG TOBACCO EXCHANGE.

At a recent meeting on the Petersburg Tobacco Exchange the following resolutions were adopted:—

In compliance with the resolution passed on the 23rd July by the Tobacco Association of Petersburg, your committee respectfully submits the following views touching the matters referred to it:

In order that planters and farmers in the southside section of Virginia, and who ship their tobacco to Petersburg to be sold, may know the kinds our trade now requires, we will state them. After doing so, growers of tobacco knowing the character of their crops, can better judge than we can, as to how they should be cured, so as to meet the wants of the trade, and at the same time, advance their own interests. Just here, we will remark, that for some years past, about nineteen out of every twenty pounds of tobacco made in the section named, and sent to Petersburg to be sold, was fired in the old fashioned way, except that it was not permitted in a majority of cases to yellow before fire was put under it. It is well known, or should be, all over the State, that for fine dark brown rich tobacco suitable for export in the leaf, and good to fine dark wrappers, that Petersburg is the best market in the country.

This knowledge caused a majority of the growers of tobacco in the section named, to go in for curing their tobacco "dark" to suit the demand referred to. Now to cure tobacco of a dark, rich, lively color, required far more skill and close attention than the bulk of the growers of tobacco had any idea of, and the consequence was a great many made an utter failure in curing it properly. The tobacco oftentimes was, just as soon as it was cut, put in the barns and then fired and smoked until the life of it was killed, and instead of the crop curing up a dark, rich brownish color, it was found to be a blackish, greenish, dead, slaty color,—without life and utterly unsuited to meet the demand for dark, rich, well-flavored tobacco. Aye more, crops which should have been cured some other way, were fired and smoked, hoping that the doing of it would make them suitable to the buyers of dark rich tobacco. The way such tobacco was cured killed the sale of it, as all the firing and smoking that could have been done to it, would never have made it suitable for those who wanted (and at good paying prices) a rich leafy, moderately fired tobacco. The honest truth is that five times as many failures have been made in our section in curing even the right kind of tobacco dark, (as the trade wanted it) as have been made in curing fine-cured kinds correctly. To come back to the points as to what kinds of tobacco the trade of Petersburg now wants, we will state them. First. The trade wants every pound of bright lemon colored fine-cured tobacco that can be grown in the South Side Section and more besides.

Second. It wants every pound of fine rich leaf, brown and bright-brown shipping tobacco that can be grown anywhere in the State, no matter if it does smell slightly of smoke. If cured so as the smell of smoke will hardly be perceptible, that will not make any difference.

Third. Our trade wants every pound of the dark, and brown leaf, suitable for wrappers for dark work that can be grown not only in the Southside section, but anywhere else in Virginia. For such tobacco our market has become the "headquarters" of this and other States. Now, it must be remembered, that in order for tobacco to suit our shippers who want brown and light-brown fine leaf, and buyers of fine dark, and brown wrappers, it must have size, be rich bodied, and perfect in the leaf, and then so cured as not to kill the life of it.

Fourth. And this includes by long odds the bulk of the tobacco sold in our city. Our buyers want a large

amount of bright reddish colored fillers, say lugs, common and medium leaf and as free from smoke as possible—indeed, the nearer it comes up to the “sun cured” flavor the better it will suit buyers. Of the tobacco sold in Petersburg in the last five years, not more (if that) than one hoghead in eight or of one pound in eight of that which was sold as loose came up to the standard required by buyers of fine shipping and buyers of good to fine dark and brown wrappers. This being so, growers of tobacco will, at once, we trust see the folly of curing more than three-fourths of the crop in a way that will kill the sale of it as fillers. Only such as have rich, heavy, leaty tobacco of good size should this year think of firing it to any extent. Planters should avoid crowding thick tobacco in the barns as is often done by putting too many stalks on a stick or having the sticks too close together. There is now no sort of demand for low, common and nondescript hard fired tobacco for shipping abroad in the leaf state—consequently the curing of all such sorts should be done in a way that will make them suitable to the trade for fillers.

To cure more than three-fourths of the crop in a manner that would kill the sale of it would be, we think, most unwise on the part of growers of tobacco. All of the present crop (unless flue-cured) should be permitted to yellow after being cut, before any fire is put under it, so as to get the tobacco of a brown, light brown, or a cherry red color. The less smell there is of smoke on three-fourths of the crop grown this year will add greatly to the sale of it. Tobacco which is sun or air cured can in very damp wet spells be kept from moulding by very small fires (made of seasoned wood, free of bark), being put under it, or, a flue could be run through the barn, and when necessary, heat enough raised in the barn to prevent the tobacco from injuring. The using of a flue would, of course, preserve the tobacco, and would at the same time cause no smell of smoke. It will also be remembered that the bulk of the tobacco grown in the Southside section tributary to Petersburg is now sold in the winter, and early spring months, during which time tobacco is not so liable to injury as it is in long, wet spells of the late spring and summer months. In conclusion, your committee wishes to impress it deeply on the minds of the growers of tobacco that our trade now demands a brighter, sweeter flavored tobacco for fillers than heretofore, and unless the Southside planters grow such, our buyers, as they have had to do this year to a considerable extent, will be again forced to go to other markets to get their supplies.

Dark, greenish and hard smoked fillers have “played out,” and there being no practical demand for such tobacco for shipment abroad in the leaf state, it must occur to the dullest intellect, that to continue to grow tobacco suitable only for fillers, and cure it up, *fired and hard smoked*, would be worse than a mistake, indeed, to us it would appear the greatest folly. We have tried to write plainly and truthfully, as we realize the situation is one of vital importance to the prosperity of our Southside growers of tobacco, as well as to the general trade of our city.—*Southern Planter*.

A TEA SUBSTITUTE USED IN THE HIMALAYAN REGIONS.

Office Memo. from Dr. George Watt, C. I. E., Reporter on Economic Products, to the Secretary to the Government of India, Revenue and Agricultural Department,—No. 51-122-28., dated Simla, the 23rd December 1887.

With reference to your Office Memorandum No. 1010-145-2A. of the 16th instant, the undersigned has the honor to reply that the supposed discovery of a new tea, therein alluded to, is a very old story. It was first pointed out by Mr. Moorcroft in 1821, that the natives of Basahr used the leaves of a species of *Osyris* as a substitute for tea. Latter on, Bishop Heber, in his visit to Almora, fell into the mistake with the native gentlemen alluded to in Mr. Lawrence's Memorandum has done, *viz.*, of viewing the plant as tea. The leaves of *Osyris arborea* (the plant forwarded along with the Memorandum) are used, here an

there, throughout the Himalayas from Almora to Sikkim, in place of tea. As in the case of the sample forwarded for inspection, they smell remarkably like tea when specially prepared; but unfortunately the infusion has powerful emetic properties which require long usage to conquer. Dr. Royle suggested that experiments should be made in the cultivation of the plant in order to discover if this emetic property could be removed by careful cultivation. The discovery of tea plant have left the matter of *Osyris* tea in the position in which it was at the beginning of the present century, when it first attracted the attention of the public.

The plant is very common around Simla; it is known as *Bahardharra*, *bakarja*, in Kumaon; *Popli* in Belgaum, and *Jhuri* in Nepal, &c. It is closely allied to the sandal-wood, but it seems to possess no properties that would justify its cultivation, since tea can be produced quite as cheap. I would suggest that one of the samples of this tea-substitute, herewith returned, be sent to Kew, since, as a Museum sample, it may be interesting to the Director, and that the other go to the Economic Museum, Calcutta, together with a copy of this letter.—*Indian Agriculturist*.

CINCHONA CROPS AND EXPORTS.

We call attention to the letter of Baron von Rosenberg on page 338 with reference to the establishment of a Cinchona Planters' Bank rather than Syndicate. This is, however, very much what is being done in Ceylon, the Syndicate agency offering to make advances on all bark consigned to it.

Our contemporary of the local “Times” estimates the quantity of growing bark in the island just now as follows:—

QUANTITY OF BARK NOW GROWING.		
Madulsima	...	2,500,000 lb.
Badulia	...	2,500,000 "
Udapussellawa	...	2,900,000 "
Haputale	...	1,500,000 "
Uva total	...	8,500,000 lb.
Rest of island	...	6,000,000 "

14,500,000 lb.

This is exclusive of stock lying in Colombo stores, probably about 2 million lb. Our own calculation is, that if Ceylon were cleared of all marketable bark at this moment as much as 20 millions lb. could be collected. But, practically, this difference in estimates is not of much importance. What is of consequence is the estimate for the current season's exports: that our contemporary makes 6 millions against the 7½ millions in our estimate. We think we are more likely to be right. In allowing for a falling-off of 3 millions lb. on last season, which gave 10½ millions lb. export, we feel we have gone as far as is safe for season 1889-90.

OIL OF EUCALYPTUS.—A correspondent writes—“Mr. S. G. Wallace of West End, Ootacamund, has for some time past been engaged in conducting a series of experiments with the oil of *Eucalyptus*. The oil is extracted from the *Eucalyptus globulus* which grows luxuriantly on the Neigherry Hills and is said to possess great medicinal virtues. It is largely used in some of the hill tracts, in Northern India, and is gradually coming into use in Southern India. It is specially effective in cases of rheumatism, bronchitis, &c., and is a good deodorant and disinfectant. The experiments made with it by Mr. Wallace have been attended with very considerable success, and the oil is said to have effected some marvellous cures, in cases of chronic dysentery. The oil has a pleasant taste and odour and is a powerful tonic. Mr. Wallace's labours in this matter are deserving of encouragement.—*Indian Agriculturist*, Sept. 14th.

TRINIDAD.—Mr. J. H. Hart, in the *Bulletin* of the Botanic Gardens, urges the planters to plant the Gros Michel Banana, as well as oranges and other fruits. The Coffee grown on the Island is also highly spoken of, and is likely to form an important article of commerce.—*Gardeners' Chronicle*.

THE FUTURE OF CINNAMON.—The *Produce Markets Review*, in quoting Mr. Jardine's letter from the *Tropical Agriculturist*, advocating the need of stopping the export of chips, has the following remarks:—

In reprinting the following letter, we would ask why should not steps be taken to promote the use of Cinnamon in England? It is a delicious spice, and is not nearly so much used in England as on the Continent; because the British cook seems to consider flavouring spices to be confined to Nutmegs and Cloves.

A JAVAN FUNGUS AT SUNNINGDALE.—Last year a very extraordinary fungus was discovered in my nursery—*Mutinus bambusinus*—a native of Java, and, I believe, never before found in Europe. How it obtained a footing here, and how it should have done so during the wet and cold summer of 1888, is a mystery, which has never been explained, and today (June 17) two specimens have matured, and two others are now in the egg-form, bursting through the ground. This curious species is figured and described in *Grevillea*, plate 173.—CHARLES NOBLE.—*Gardeners' Chronicle*.

THE OYSTER FISHERY AT BENTOTA.—Mr. A. Haly, the curator of the Colombo Museum, has just come back after a trip to Bentota, whither he went to inspect the oyster-fishery, and his investigations, the result of which he told our reporter this morning, were of an interesting character. He said that the fishery is one of perfect simplicity, and at present of a very small extent, though it may be increased indefinitely by very simple means. The oyster, he pointed out, will live in brackish water; but it requires a clean vertical surface of gneiss, protected from the force of the waves. A very good instance of this is to be found in the large number of the edible oysters that are to be seen now clinging to the breakwater in Colombo harbor. The oysters grow very rapidly, and when six months old are fit for the table. So much for the habits of the mollusc. The Bentota fishery, he says, is one of small extent, oysters not being found for more than two miles up the river. It is only on the boulders of the river that they grow, and there are not many of these. The best bed is the bridge itself. He does not think the present export can possibly exceed 3,000 oysters a week. The greatest enemies of the oyster are the floods, and the use of dynamite for killing the river fish, and unless this latter practice is put a stop to, he says, it will be soon all up with the fishery. The demand is largely increasing, and whereas ten years ago there were only two or three divers employed, there are now nine or ten. When the railway line has been carried as far as Bentota he thinks that it is not unfair to estimate that there will be a demand of at least a thousand dozens a week, that is, putting it down that a thousand people would want oysters, and that they would eat one dozen each—by no means an exaggerated estimate of the number who would require oysters or of the number of oysters they could consume. But if this demand did come about and it were met, the river would be exhausted in a very short time. The question then is one of how the fishery can be extended, and he thinks that the number of oysters there can be indefinitely extended by building some narrow stone causeways into the river from either bank. As stated above, the oyster clings to any vertical piece of rock, and these stone erections, he thinks, would answer better than piles or any of the other numerous methods employed by the French and Chinese. The outlay would be small and Government having built the causeways could either make the affair a Government monopoly or lease the causeways to private individuals. Mr. Haly will send in to Government a report to this effect, we believe, very shortly, and his suggestions seem to us so reasonable that we think Government are pretty certain to adopt them.—Local "Times"

SPECIALISTS IN MICA are taking great interest in the statement that mica has been discovered in several places in Australia, notably in South Australia at Champion Bay in Western Australia, and in New South Wales. Mr. Richard Baker, of 6 Cross Lane, London, who has been interested in mica since 1858, is notably interesting himself in the matter. The more, of course, electricity comes into use, the more mica will be in demand. It is found, and exported already, from Siberia, India, and Canada, but these countries do not nearly supply the demand.—*European Mail*.

AGRICULTURAL PRODUCTS IN THE UNITED STATES.—According to the official returns of the American Minister of Agriculture, the following was the value of the products raised in the Republic in the financial year ending June, 1887:—Potatoes, 78,441,940 dol., of which were exported to the value of 258,694 dol.; Sweet Potatoes (the *Batatas edulis*), 20,400,000 dol.; Peas and Beans, 13,800,000 dol., of which were exported 450,000 dol.; other vegetables, 68,000,000 dol., of which were exported 250,518 dol.; fruits 175,000,000 dol., of which were exported 1,601,979 dol. grass seeds, 15,000,000 dol., of which were exported 638,329 dol. Wine production, 10,000,000 dol.—*Gardeners' Chronicle*.

A NEW VARIETY OF MANGOSTEEN.—Our readers will remember a description by Mr. Meston of fruits which he brought down from the North after his first ascent of Bellenden Ker. On the recent Scientific Expedition Mr. F. M. Bailey, Colonial Botanist, saw both the tree and the fruit of the largest species, and brought down specimens for examination. Mr. Bailey has made the interesting discovery that this splendid fruit is entirely new, that it belongs to the Garcinias, the same family as the famous Mangosteen, and is the first of the genus ever discovered in Australia. Mr. Bailey has decided to name it *Garcinia Mestoni*, or "Meston's mangosteen." A full description of this new fruit will doubtless appear in the account of the expedition.—*Queenslander*, Sept. 14th.

INTERCOMMUNICATION IN CEYLON PLANTATIONS: WIRE ROPE BRIDGES, &c.—A little time back you published some remarks with reference to the desirability of increasing the facilities for intercommunication upon estates. I was chatting with Mr. John Brown recently about these, which seemed specially to have attracted his notice, and he was telling me of measures he had himself adopted on some of the properties in which he is interested to give furtherance to the suggestion put forward by yourselves. He told me that he had erected several light bridges of wire rope which had proved of material aid in enabling work to be carried on on his estates. Four wire ropes are strongly strained across the streams intersecting his properties, and on these are laid cross bearers, upon which again the flooring planks are nailed in the direction of the line of the bridge. This system of planking gives considerable stiffness, staying the tendency to "sway" to which such rope bridges must necessarily be liable. It was suggested by me that this tendency might be still further controlled were the ropes separated by pieces of wood arranged on what is known as the "herring-bone" method, and every two ropes at certain portions of their length thereby strained in opposite directions. Mr. Brown admitted that such a system might be usefully adopted, but he told me that even as he had constructed those he had put up they were quite stiff enough to bear crossing on horseback. The expense of these bridges up to 30 or even 40 feet span is quite inconsiderable, and it will readily be realized by those well acquainted with the formation of your hill estates what valuable aids they must prove to be to intercommunication upon them.—*London Cor.*

Correspondence.

To the Editor.

CATTLE MURRAIN.

School of Agriculture, Colombo. 20th Sept. 1889.

SIR,—I send you the following observations made by me with regard to the disease affecting cattle at present, with the hope that they may direct attention to the need for greater precautions against disease, on the part of cattle-owners. I have within the last few weeks seen two or three cases of the so-called "murrain." To begin with I found that the affection was not "murrain," at least in the general acceptation of that term in veterinary pathology,—the term murrain being synonymous with "foot-and-mouth disease," from which it seems to be particularly distinguished in Ceylon, as I read of such expressions as "hoof-and-mouth disease and murrain" and distinct prescriptions for the two. People in Ceylon, however, may insist on their own nomenclature of bovine affections. To avoid confusion I would suggest that the disease in question be styled "Ceylon murrain." What then are the characters of the disease? The ordinary milkman or cartman will tell you that the first symptom of disease in his animal was a drooping of the ears and hanging down of the head; next it ceased to feed and ruminate, while respiration gradually became more difficult; that it inclined to swell about the barrel; and finally sank down never to rise again. In company with the acting Sanitary Officer I visited two cattle-sheds and saw animals that were victims to the so-called "murrain." The mouth and feet were perfectly clean in every case. In the last case, which resulted in the death of the animal on Tuesday morning, we performed a *post-mortem* a few hours after. The examination revealed that the different organs of the body were almost perfectly healthy. The lungs were congested to a slight degree, but otherwise there was nothing to attract attention except the condition of the rumen. This was distended to an inordinate extent, and on puncture emitted peculiarly noxious odours. Moreover, it contained an unusual amount of food in a highly decomposed state. I should mention also that the animals I examined were also suffering from catarrh, as shown in the discharge from the nose and eyes, with a tendency to fever, the extremities and ears being generally cold in contrast with the hot condition of the other parts.

Now with these data before me, and knowing nothing of the nature of previous attacks, but merely comparing the character of the affection with surrounding conditions, I am forced to the conclusion that the attack called "murrain" in Ceylon is induced by certain atmospheric conditions. The nature of the weather during the past few weeks combined with the unconcern with which the necessity for protection from its inclemency is looked upon, causing both cold and fever; the wet and musty food supplied, resulting in tympanitis and impaction of the rumen; and lastly the *post-mortem* evidence: all these I say go to strengthen the opinion expressed as to the cause of the attack. The Sanitary Officer, moreover, asserts that just in those cattle-pens where the animals were exposed to the weather, where dampness and moistness were the prevailing qualities of the pen and food, did he observe attacks of "Ceylon murrain" breaking out. Some aver that the affection is contagious, but the predisposing cause of the attack is so common, namely want of care both in housing and feeding under special circumstances, that there

is little opportunity of judging whether an attack after the arrival of certain animals in a district was due to the presence of such animals—in fact whether it is a case of "propter hoc" because it was "post hoc."

Under the circumstances it is natural to suggest better care of the animals especially under peculiar conditions of weather and of the atmosphere; dry housing; and particularly sound food, that is food that is not damp or musty, owing probably to being cut wet and stored badly. Unsucculent food should be supplied as far as possible as, I believe, has been suggested already, but certainly an instantaneous change of diet is necessary, cooked food supplying a convenient and wholesome change. Drugs for the relief of the animal have already been suggested and found efficacious in the hill-country. My observations of the character of the so called "murrain" strongly reminded me of an epizootic attack known as "pink-eye influenza" which broke out among the horses in Edinburgh two years ago. Principal Williams used to describe it as an "atmospheric disease" usually coming on after a season of wet weather when the ground is saturated with moisture; though there was a general opinion that the attack was contagious, he held to the contrary, and laughed at the municipal authorities for boarding over the city water-troughs for horses. He was afterwards able to show cases of affected and healthy animals standing side by side in his infirmary, and say of the latter, "They have escaped because they stand in a well-protected and dry stable." I have already over-stepped the limits I intended confining myself to. Certain suggestions as to the necessity of inspection and other points bearing on this subject, I must reserve, probably to be dealt with in the coming issue of the *Magazine of the School of Agriculture*.—Yours &c.,

C. DRIEBERG, B.A., F.H.A.S.

MARKING CEYLON TEA PACKAGES.

Colombo, Sept. 20th.

DEAR SIR,—Messrs. I. A. Rucker & Bencraft in their weekly Tea Circular of August 29th refer to a letter of mine appearing in the *Overland Ceylon Observer* of July 22nd, on the subject of making Ceylon tea packages. Messrs. I. A. R. & Bencraft's recommendation that packages should bear an invoice or break number instead of a separate No. for each package is a good one and an improvement on my own.

An invoice of say 100 packages would therefore be marked thus:—

25 packages B. P. all No. 1
45 " Pekoe " 2
30 " P. Sou. " 3

the next invoice beginning B.P. No. 4, and so on.

i As regards marking packages with the net weight it is of course of no use from a London point of view, but for teas offered in local sale, it is very necessary, from a buyer's point, as it enables him to readily check, in the rough way, estate net weights by taking the gross. Occasionally important mistakes are rectified in this way. As buyers very rarely turn out tea in Colombo, (in practice it is impossible), accepting estate weights as correct, it is only right that planters should give buyers every facility to enable them to ascertain if estate weights are about correct. We all know that scales are apt to get out of order in this climate.

In addition to the foregoing, the net weights being marked on the packages enables the Customs to ascertain if the Harbour dues, paid after shipment, are correctly paid or not, the dues varying according to the weight of the package.

I find my Australian friends like to have the weights marked on the packages; it is, however, not absolutely necessary that they should be marked.—
Yours faithfully,
F. STREET.

TEMPERATURE OF A TEA LOFT DURING WITHERING.

Theberton, Ambagamuwa, Sept. 24th, 1889.

DEAR SIR,—In your issue of the 21st instant, you have a leader on Mr. Hughes' remarks, as regards the effect of temperature during the withering of the leaf on the tea made.

I have kept the temperature of my withering loft for years and also for sometime a hygrometer. As far as I have been able to observe, variation in temperature has little or nothing to do with the quality of the tea made, nor can I find much practical use in the hygrometer. The variation in the quality of the made tea, seems more to be connected with the weather the leaf flush has grown in and also the health of the tree and state of the sap.

Strong healthy trees and a good climate are the chief requisites for first-class teas. In fact it is more in the field than the factory that high-class teas are made: as I believe is generally allowed.—
Yours very truly,
T. J. GRIGG.

THE EXPORT OF ANNATTO SEED FROM CEYLON.

DEAR SIR.—For some time back the export of annatto seed even of the best quality has been a bad business. It seems a pity then that people should present in shipping poor qualities to their own loss and to the injury of Ceylon's good name. I enclose cutting of the last market report, and you will see that some Ceylon seed failed even to get offer. Much the same thing is going on with annatto as with tea—a falling market, oversupplies, and Ceylon displacing other countries. I hope this present year to harvest not far short of a million pounds of annatto seed besides what I buy from others, but then long care, labor and money has enabled me to surpass the West Indies in quality; and the better price I thus got, and the large scale on which I now work enables me to carry on at a profit, and hope for better times—“*survival of the fittest.*”
A. G. K. BORRON.

ANNATTO.—Seed: 9 packages, 5 of which not landed, and 4 cases, from Ceylon, not drawing any attention, were taken out, no price being mentioned. Roll: 15 baskets, imported via New York, of good colour, bought in at 1s.—*Chemist and Druggist*, Sept. 7th.

THE CINCHONA BARK PROSPECTS AND THE PROPOSED SYNDICATE.

A CINCHONA SYNDICATE AN IMPOSSIBILITY—A NEW LINE OF THOUGHT AND A PLAN OF ACTION—A PROPOSAL FOR CINCHONA AGENCY HOUSES IN ENGLAND AND HOLLAND AND HOW TO MANAGE THEM—A GUARANTEE OF SUPPORT INVITED FROM BARK PRODUCERS AND WHAT THEY WOULD GET IN RETURN—OPINION OF AN AUSTRALIAN FIRM ON THE SCHEME SUGGESTED.

Manalé, Devicolum, Sept. 30th, 1889.

DEAR SIR,—From the various replies I have received from Ceylon and Java, I can very well see that such co-operation as I formerly proposed is impossible however much desired by planters.

The various causes have already been put before your readers and I will not re-enter upon them. When Ceylon with the exception of a few estates is out of cinchona it might be different.

The correspondence which has ensued has, however, no doubt been of value, and by means of it I have been led into a new line of thought and a plan of action has suggested itself to me which seems more feasible and void of the objections to my first proposal:

A suggestion in some sort of the plan of campaign I wish now to propose was made to me in a letter from Holland by a gentleman who has large and responsible interests in Java cinchona. His letter was privately addressed to me and I do not know that at present I am at liberty to disclose his name.

The “gist” of his proposal, however, was to the effect that a so-called Cinchona Consignment Bank should be formed in England and Holland to receive bark, pay an advance of, say, 1d per unit against it and settle accounts on sale. As far as I can understand this was to go hand-in-hand with my original proposal. I do not, however, see the necessity of this.

I will therefore try and give the idea I have now formed in my own words. Let a Consignment Bank, or rather call it a House of Agency, with ramifications in Holland and America, be formed. That House would offer the usual rate of advance to planters on produce and agree to settle accounts on sale of such.

Let us suppose that a very large percentage of the bark which now filters into the market through the various houses found its way into the hands of this one large House.

Let us further suppose that planters consigning to this large firm gave it reasonable powers of holding produce. There is no doubt that such a house would have a very large power in influencing the market and obliging middlemen to be contented with a fair profit instead of the exorbitant one they are making at present.

Such a firm would possess all the statistics of the market and would be able to work strictly on the supply and demand principle. Were it to go beyond this it would become a corner and as such be liable to disaster.

But to enable such a firm to start at all a declaration is necessary on the part of the larger proportion of cinchona producers to the effect that they would help the scheme by consigning their produce to such firm or firms.

Planters could lose nothing by doing this and they might gain a great deal.

They might in the first place crop by uprooting or otherwise as much bark as they wished and they would get their usual advances on such crop (such advances could I have no doubt be fixed at 75 per cent of value).

Should it then be found that this “large firm” could not influence the market for a rise they would still get the same price for their produce which they would have got without it.

But the chances are they would get a far higher price, for it is not only presumable, it is almost certain that a very great and very salutary influence would be exerted upon the market by such a firm, holding a large amount of bark for only a short period.

Let us suppose that such “firm” were the appointed receivers of 90 per cent of the bark produced, let it only put a small quantity or even say none at all of its received produce into the sales for a few weeks and the purchasers would be brought to terms at once. The unit would double itself even though wholesale prices of quinine might be increased.

But to give a firm this power of starting and working, we planters must be the first in the field.

Let, as you propose, a Committee of two be formed in Ceylon, India and Java entering into communication with each other on this and various other questions. Let them canvass among the other planters through the various Associations for adherence to some such proposal. Let them try to get the men with one acre with 20 trees as well as

the large holders of cinchona to agree to consign their bark to such "House" when started, and I don't think there would be any great difficulty in getting the House to start.

Much as you have honoured me by proposing my name as one of the Committee I would suggest that there are far larger and more influential cinchona planters in India than myself and that it would be more for the public good to appoint one of these.

I am at present in communication with a large firm who are both bark holders in this country and agents for bark at home.

I have placed my Amsterdam correspondent's letter before them and asked them to give me their mercantile opinion in the matter, and whether they would themselves be willing to help in the formation of the "House."

There is no doubt that such "House" would pay simply through the commission usual on sales of bark.

From Java planters we are already in possession of an expressed willingness to join any reasonable scheme of co-operation.

There is only one objection to the scheme I now put before you, and this is the possibility of planters being so heavily indebted to their agents that they are not at liberty to choose their consignees. This, however, I trust is not generally the case.

I subjoin extracts from my Amsterdam correspondent's letter.—I am sir, yours faithfully,

J. V. ROSENBERG.

"I fully share your opinion that should co-operation of planters be possible considerably better prices for bark would very soon be realised.

"My proposal would accordingly be that a committee of British India and Ceylon planters be formed, which Committee will have to go into all the details and facts relating to the Indian and Ceylon plantations and their quinine percentages. When the Committee shall be thoroughly 'an fait' it should proceed to Java armed with all particulars and let the Java planters have the needful light on the subject and so convince them that only co-operation can lead to better prices.

"As everyone will clearly see that a co-operation of the kind will be of benefit to all parties, it could accordingly be brought about but for an obstacle, which has still to be overcome, and which to me seems far more serious, viz:—

"The low prices have caused great losses not to speak of the general distrust of cinchona cultivation, which followed as a matter of course. These losses and the distrust they gave rise to are a hindrance to planters getting any fresh capital for working their estates. They are therefore forced to sell their crops at any price, which is their only means of keeping their estates going. Now many planters, however glad they would be to co-operate, in order to realise better prices, in some manner or other, are actually prevented from doing so in view of the above disadvantages. To me it seems that the league you desire could only be formed, if in England and Holland the needful funds could be found for the establishment of a *Cinchona Consignment Bank*.

This Bank against a charge of interest and commission would have to allow to all planters forming part of the cinchona co-operation league on receipt of their produce a certain advance, say a penny per unit. The board of the Bank would have to decide at what figure the unit should be kept and the Bank could of course settle accounts with consignees according to sales.

"In your letter you refer to a possible disadvantage to consumers in case your proposal should be carried out, but I believe no such fear need be entertained. It is in the interest of planters not to advance the price too much (we desire no imita-

tion of a Copper or Tin Syndicate), and the following is to be borne in mind, viz. that a kilo of sulphate of quinine is sold here for 20 fs. that out of one kilo 15,000 grains of pills are made that the public pays 2½ cents Dutch (a halfpenny), per pill of one grain and that according by one kilo sulphate is sold to consumers for 375 fs. on which a profit of 355 fs. is made!

"With a unit price of 3d, all planters would be satisfied and at that price, manufacturers, and the retail trade would still clear a splendid profit, without the latter having to raise their price for consumers.

"It may be that in other countries than Holland, and taken wholesale, prices for consumers are cheaper; but no doubt these figures would still leave an ample margin for planters to make better prices without a rise for consumers being necessary.

"At present I believe the market is wholly in the hands of manufacturers, the great supplies added to the knowledge that co-operation on the side of the planters does not exist, enable factories to 'bear' the market. Most manufacturers sell great lots, forward delivery and when the auctions come they make low offers of their manufacture, all in order to get the new produce cheaper and cheaper still. In their advices manufacturers continually point to the large stocks in 3rd hands but they never mention that the stocks of bark which they themselves previously held, (viz. invisible stocks) have given place to large uncovered wants on their side.

"I believe sufficient causes are at work to warrant planters in asking higher prices. We need no longer be afraid of South America, nor of an extension of plantations in Ceylon, India or Java. In spite of the efforts of some people to conceal the truth, the consumption has increased, for stocks in third hands have in no way swollen in proportion to the greater production.

"Nothing would be more gratifying to me than to lend you a helping hand, and should you approve of my scheme of a Cinchona Consignment Bank and further the same by recommending it both to your own connections and those of your friends in London, I could then open negotiations with them and try to carry out the scheme."

COORG COFFEE AND COFFEE UNDER SHADE IN CEYLON.—We have a long and interesting paper from Mr. J. P. Hunt of Mercara on the cultivation of coffee under shade on page 350. Meantime, we attract the attention of gentlemen intending to experiment with coffee in Ceylon under shade, to the advertisement in which Mr. Hunt offers to supply carefully picked Nalkanaad seed. There is no doubt but a time of very high prices for coffee has set in.

"PENNY QUININE."—Some time ago, we dwelt on the good done by the enter-prise of this gentleman in making up quinine pills in small boxes and at a price within the reach of "the million" with circulars giving full information printed in all the languages of the East. Mr. Hicks has now organised his scheme into a regular business and it is this which he is advertising and for which he now wants responsible agents in every turn in Ceylon, India, the Straits and China. We wish Mr. Rivers Hicks a large measure of success. We feel sure that if persevered with, this business must grow to be very large indeed. In China especially, there is room for an immense consumption of quinine and the Chinese are ready to pay for the invaluable febrifuge which they have practically tested as a substitute for the poisonous opium. Here, too, in Ceylon and especially in India "the million" ought to be able to buy penny pills of quinine very readily and to thank Mr. Rivers Hicks as a public benefactor for making cheap quinine so universally available.

LOWCOUNTRY PLANTING REPORT.

WEATHER AND RAINFALL—COCONUT CROPS AND LEAF DISEASE—THE COCONUT BEETLE—A NEW METHOD OF CULTURE.

Hapitigam Korale, Oct. 11th.

During July, August and September of 1888, we had not a shower that run to two figures in cents, and the aggregate rainfall of the three months was only 2.05 inches. In the current year the rainfall was

July	6.33 inches on 22 days.	
August	6.56 "	17 "
September	18.37 "	23 "
	31.26 "	62 "

From 28th Feb. to 30th June, there fell 52.34 inches, so that in seven months we have had 83.60 inches. Not bad that for a rather dry district.

The coconut crops of the present season have been deficient both in size and number in consequence of last year's drought, but the promise for next year corresponds with the abundant rainfall of this. The young fields that were thrown back last year are now endeavouring to make up for lost time. The leaf-disease that threatened such serious consequences at the beginning of the year has ceased to give any anxiety. In the very worst cases, no spotted leaf has been developed for the past three months, the only remaining effect being a slower growth than usual, indicating I think, that such plants had to make fresh roots to replace those rendered useless by the drought.

As B. has taken a good deal of trouble about this leaf-disease without reward either in pecuniary result or lasting fame, a state of things much to be regretted, we coconut planters should do something for him, and as this appearance of the leaves has no name, it has been suggested that it should henceforth be known as the *Bevanee*.

I have lately lost several trees from the *Kandapanuwa*. They only attack a tree in vigorous growth, and the most dangerous period is just when the tree shows stem above ground and swells out into a bulb which splits the leaves in the middle while still fresh and succulent. All my recent losses have been due to this cause, the beetle deposits its eggs in the broken leaf which supports the grubs till they acquire strength enough to penetrate the stem. The only way to prevent this is to remove every split leaf as soon as it appears and to this end an almost daily inspection should be made of all trees in this particular stage of growth. The removal of the cracked leaves is a very delicate operation, requiring great care and it would be well to use a special knife, one without a point and with a slight curve. When the pest has once established itself in a young tree, the sooner it is cut up into chips and roasted the better. I approve of the Straits law that makes this compulsory, but not of that part that makes the possession of dungpits penal. The *kuruminiya* disfigures but does not kill the tree, and as they increase in age, they become less and less liable to its attacks, kill all grubs that turn up in the course of working an estate, but there is no necessity for any special law, indeed such a law must be inoperative, because agricultural success depends greatly on those very accumulations of manure that this law renders criminal.

I have long been of opinion that garden culture was the best way of dealing with coconuts, but it is only lately, that I have tried it on any important scale. I have now had a bit under experiments for twelve months with so far the most satisfactory results. The land selected was past five and past six years and not by any means good at its age, very unequal and the land exceedingly dirty. It was twice dug over mamottie deep, weeded as often as necessary, was moderately manured and is now perfectly clean, the only remaining weeds being pasture grass. The plants are growing as a rate I have never seen equalled, some of the most advanced, developing a fresh leaf every twenty days. This is a very unusual rate of growth, even on rich soil, that is not clean, well pulverized and aerated and if this treatment were begun early, and kept up: there seems little doubt that the trees would be in full bear-

ing in half the time that they usually take. Will it pay is the question, well we will see.

In addition to the 83.60 inches of rain from the end of February to the end of Sept. we have to add up to date.

HOW TO MAKE TEA.—TEA AND BOILING WATER.

TEA AT HOME.—As the daily papers are not overwhelmed with news just now, tea continues to serve as a useful subject for comment. The *Daily Telegraph* of Saturday last gave its readers nearly two columns on the subject of tea and coffee and the art of making it.

It published a letter from Mr. J. Carter Bell, county analyst for Lancashire, in reply to one from Messrs. Brooke, Bond & Co., in which the statement of that firm, as to tea being better when made with water just boiling, is distinctly contraverted. Mr. Bell says:—"Last winter I was asked to give a lecture on the 'Chemistry of the Breakfast Table.' Before doing so I made some special experiments upon the action of boiling water upon tea, and my results proved that no ordinary person could tell whether water had boiled for ten minutes or for ten hours. To put this question further to the test I prepared three samples of water, and numbered them 1, 2, and 3. No. 1 was distilled water which had boiled for about three hours; No. 2, Manchester water drawn from the main into bottle; No. 3, Manchester water, boiled for ten hours under an inverted condenser. These bottles of water were sent to a gentleman who had been tea-taster for forty years to one of the largest tea firms in Manchester, with a request that he would kindly say which was the best water for tea-making. The following was his report to me. (The water was tried upon three different kinds of tea):—Name of tea—A strong medium Moning: (1) Distilled water developed best flavour. (2) Manchester water stronger, less flavour than above. (3) Water boiled for ten hours, strong but insipid. Name of tea—Our Russian tea: (1) Distilled water, flavoury, but pale. (2) Manchester water, stronger than above, flavour inferior. (3) Water boiled for ten hours, strong and good, flavour inferior. Name of tea—Finest Darjeeling Golden-tipped orange pekoe: (1) Distilled water, bright liquor, good, bouquet wanting. (2) Manchester water, exquisite flavour and strength. (3) Water boiled for ten hours, very strong and good, muddy. This gentleman summed up his report by saying:—No. 1.—Though paler liquor than Nos. 2 and 3, the infusion is much the best of the series, and uniformly good. No. 2.—Draws dark liquor, but develops lower better, relatively, than higher qualities. No. 3.—Though rather muddy the strength is best of the series, and uniformly good. This report rather tends to show that water which has long boiled makes better tea than water just brought to the boil. This is a question which can only be settled by the test of experiment."—*H. & C. Mail*, Sept. 27th.

Sir,—We notice in your issue of Wednesday a reference to a few hints we have recently given on this subject. You say "first and foremost the water should be poured on the tea the moment it boils, because continuous boiling renders water incapable of properly abstracting the aroma. This fairly represents what we said on this point, and we thought our remark so trite as to be almost superfluous. But we notice it has been received with scepticism and contradiction. One of the best and most influential papers in Great Britain—*The Manchester Guardian*—in some courteous observations on our suggestions says on this particular point, "Now we are quite aware that this is a

popular belief, but we are by no means convinced that it is not a pure superstition," and Mr. J. Carter Bell, the county analyst for Lancashire, states in a letter to a contemporary: "I beg to differ totally from Messrs. Brooke, Bond & Co.'s experiments which I have made tend to show that water which has long boiled makes better tea than water just brought to the boil." Against these expressions of opinion we can put the popular belief to the contrary and the general practice of the trade. Undoubtedly it has been the rule for generations with Mincinglane tea tasters to pour on the water immediately it boils. However, there seems to be a conflict of opinion where absolute unanimity might have been expected. The point has considerable interest and no little importance. Considering the vast number of hardened and shameless tea drinkers of both sexes who are interested in this subject, a positive, incontrovertible opinion from some of your scientific readers would be a boon. It would certainly be welcome to the trade and to your obedient servants,

BROOKE, BOND & Co.

17 and 18, St. Dunstan's-hill, E.C.

—*Daily News*, Sept. 27th.

COCA CULTIVATION IN THE EAST INDIES.

The director of the Botanical Gardens at Buitenzorg (Java), in his last report, makes some observations concerning the cultivation of coca leaves in the Dutch East Indies, which go some way to confirm the view that before many years are over a not inconsiderable proportion of our requirements in this article may be supplied by the Java planters, unless indeed the market price of the drug should further depreciate to such an extent as to render the culture of the plant absolutely unprofitable. The climate of Buitenzorg, and presumably therefore of a very large portion of Java, is now proved to be excellently suited for the propagation of the plant. A trial plantation of not quite $\frac{1}{2}$ bahoe ($=\frac{1}{2}$ acre) area gave four crops of leaves during the year 1888—viz., in February, April, June, and September, the total weight of dry leaves obtained being fully 360 lb. It would seem from these data that, given favourable circumstances and intelligent cultivation, an acre of coca plants might be made to yield a crop of about 400 lb. of leaves, which, if properly cured and of fair quality as the drug now goes, ought to realise at least 20% in Europe, and therefore be a far more profitable crop than cinchona is now. Last July the Buitenzorg Gardens were visited by a prominent German cocaine manufacturer, with whom the directors of the gardens had a long interview concerning the best way of growing and curing the drug, and making its cultivation a commercial success. As a result of the interview, two samples of coca leaves were sent from Buitenzorg to Germany for analysis; one of the samples (of about 45 lb.) consisted of slowly-dried leaves, the other of leaves which had been dried as quickly as possible in the sun and subsequently reduced to fine powder. The leaves sent to Germany were of the small varieties which, when previously tested, had been found to be of the greatest alkaloidal richness. The slowly-dried sample was found to contain 0.34 per cent. of absolutely pure cocaine alkaloid. The second sample of 60 lb. of sun-dried and powdered leaves only yielded 0.14 per cent. of absolutely pure cocaine. The latter shipment when received in Europe showed leaves of a bright green colour, but without the characteristic smell. The quick-drying system, therefore, appears to exercise an unfavourable influence on the alkaloidal value of the leaf. Another sample of the second variety was sent to Europe through a Batavia shipping house, analysed by another firm, and gave the same bad results as the first, the sale price being one at which it could not possibly pay cultivators to grow the drug. The conclusion of these trial shipments has been to prove beyond doubt that the mode of gathering and curing the leaves exercises a very decided influence on the percentage of cocaine yielded by them, and that

in order to make the cultivation of coca a paying industry, the most scrupulous account must be taken of the variety of leaves grown, the time for gathering and drying the crops, and the mode of packing and shipment. But if these conditions are carefully kept in view, we should say that it ought to pay Java and Ceylon planters to grow coca to a moderate extent, not as a chief crop, but as one of those smaller adjuncts to their staple which, though not yielding riches in themselves, are specially useful in seasons when the receipts from the large crops show a decided falling off.—*Chemist and Druggist*.

COFFEE-PLANTING ON THE NILGIRIS.

SIR,—When the above catches the eye of men who have been planting in this district for the past twenty years, it will doubtless bring back to them vividly, the various vicissitudes the industry has undergone; doubtless, too, they sigh for the "good old times." Coffee-planting in 1869 and the same in 1889 are two very different undertakings. Then, the shrub had only to be planted; it grew and gave crops; now it is a very different matter. The object of this letter is not to recall the happiness of the past, but seriously to look into the future of the industry in our district. There is no doubt whatever that a feeling of uneasiness exists among those concerned in Coffee on the Nilgiris. The primary cause, of course, is leaf disease—this has been unusually early and virulent this year, but, as yet, there is no cause for alarm. As a Nilgiri planter I consider this year's virulent attack the result of last year's terrible drought, for when it is remembered that estates literally nearly died out for want of rain it stands to reason that the trees were weakened to such an extent as to make them most susceptible to the disease, and I contend that the bushes have not yet recovered those trying months of last year. This is borne out by the unsatisfactory way the trees have blossomed this year, for the wood which now bears the standing crop was in existence during the drought. Be the cause of leaf disease what it may, it behoves planters now to look it steadily in the face and cope with it. Every conceivable remedy for its eradication has been tried, but so far without success, and men are only now beginning to see the only feasible cure, viz., shade. If only they had tried this some five years ago the valuable properties on these hills would be now in a very different condition. However it is not too late; the majority of the estates are in good heart and very valuable still; let all concerned, then, without the loss of another year, see about planting all over their coffee say at distance of 20 feet \times 20 feet, shade trees, choosing of course the class of shade adopted to the elevation of their estates. Jack, &c., for lower elevations, and cedars, &c., for higher. It will be utterly useless to try partial shade. The whole estate must from the first be planted thoroughly and throughout, and it is my firm belief that, if every estate was under shade, leaf disease would receive a fatal blow. It may be contended that very small crops will be the result of shading high elevations, but this is a mistaken idea, for if the shade trees are kept trimmed up high and opened out a bit, the coffee under them will bear just as heavily and not suffer so much as bearing a crop in the open; but even granting that such heavy crops are not realized under shade, I am sure there is not a planter who will deny that more regular crops will be obtained and the estates will last twice as long. Shade has other advantages; not half the amount of weeds will have to be contended with, less manuring will be required and pruning and handling will be far easier and cheaper. Some affirm (and it is so too) that trees under shade are not entirely free of leaf disease, but it is quite forgotten that when this has been found to be the case it is in a field of 5 or 10 acres of coffee riddled with the disease and perhaps only one shade tree protecting 20 bushes. How can these latter escape? But even under this hard test, the few trees look decidedly healthier than those outside the influence of shade. To those whose estates are in a critical

state in consequence of age and the disease there is nothing better than a dense growth of castor oils, say 12 ft. x 12 ft. At the same time should be planted more substantial and lasting trees; when these latter have grown the castors can easily be rooted out. Generally speaking, there is many a good year in store for our district; and let men say what they will (alarmists exist in every community) the Nilgiris will remain to the front in the coffee-planting world. Nilgiris, 30th Sept. L.H.P.

—Madras Mail

THE COFFEE PLANTER OF TO-DAY IN SOUTHERN INDIA.

The day has long gone past when a planter may hope to eat his bread simply in the sweat of his brow. Thorns and thistles will the earth bring forth, lantana and scrub, if besides his brow his brain is not well sweated. The coffee-tree has by high cultivation now reached a position very nearly analogous to that in which the nineteenth century man stands to his ancestor of the ninth century. As its powers of production are increased, we may feel quite sure that diseases, before latent, will be developed, and that it will fall an easy prey to its many insect enemies, if constant and unremitting care is not devoted to it, and all the resources that science, deep thought and manifold experiments can afford, are not brought to bear on it. To attempt to cultivate coffee by any hard and fast rules except in the most general way, is to try and lay down a mosaic with foot-rule and square, or to woo and win a maiden according to a two-penny ha'penny "etiquette of courtship."

There is no doubt that the position of the planter is greatly improved as compared with what it was in the memory of many. Roads there are everywhere, and though at the end of the monsoon they may be nothing but ruts and holes, yet they are certainly better than mountain tracks and the beds of torrents up which many a planter has before now had to climb to reach his estate. The mud-and wattle hut has disappeared, and in its place are substantial bungalows of brick or rammed-earth or else built of planks of different timber, tastefully fitted together and polished. Inside, all is neat, simple and homely; there is no room for ostentation even if it were desired, but there is room, and yet never room enough, for comfort and kindly hospitality. Outside, a garden blooms with many a sub-tropical flower, and the air is sweet with roses and violets, and the memories they recall of the gardens of England; a small well-kept lawn there is sure to be, and possibly a fountain or a tiny miniature lake: the whole evidently the pride of its mistress, or the hobby of its master, if he be a bachelor. Few districts have not felt the refinements of married life, and there is a growing disposition for men to take unto themselves wives and to plant among their coffee trees their Lares and Penates.

To an outsider, coffee planting often seems simplicity itself. It is simple: as simple as for a professional jockey to win a race by half a length without moving hand or foot. The two qualities essential for a planter are infinite patience and unflinching hope, no mean virtues. His troubles are usually trivial, as small as the spears of Lilliput, but as numerous. In each year there comes a crisis to all but the very fortunate, a time of looking towards the sea and seeing nothing, of watching a little cloud arising like a man's hand and passing away, of beholding the heaven black with clouds and wind and hearing the roar of the rain as it falls a mile away but not on his plantation, of gazing at the mocking splendour of the rainbow as the shower dies away and the sun shines again. At length the rain falls, but too late, so that where he expected his trees to bear forty-fold, they only bear ten-fold. All that is left for him to do is to plod steadily through another year and hope for better luck next time. His chief failings are grumbling, and a too ready suspicion of those with whom he stands in a business relation. It is curious that these failings appear to be inherent in those who directly depend on nature for their living

The former can be readily understood, but the latter not so easily, when it is remembered that along with it usually goes great hospitality, a marked sense of justice, and that charity which is slow to think evil of any man. A planter is an artist in the highest sense of the word. With jungle desolation and fever-laden forest for marble block, with axe for chisel, and health and wealth for mallet, his studio the vault of heaven, bright with the sunshine of day, or filled with the starlit silence of night, broken only by the mournful moan of an owl or the short sharp bell of a sambhur, does he, a second Pygmalion, carve forth another statue which shall presently throb with the pulses of life and be rich in the beauty of vivid existence. Much has been spoilt, we will admit, and there are many tracts of abandoned coffee estates which appear great disfigurements to the eye of the enthusiast forester. Not that the work has been done wantonly or idly. These abandoned estates are the lessons of experience and he who fails wrestling with nature is not disgraced. In coffee it is as in almost everything else the only thing that really succeeds is success. Nor must it be overlooked that to bring an acre of coffee into bearing—and few if any estates are abandoned till long after this—means R200 for the ryots of India. If there is any truth in that opinion that he who can make two ears of corn or two blades of grass to grow upon a spot of ground where only one grew before, deserves well of mankind, and does essential service to his country; surely a planter will rank high as a benefactor and a patriot. "Out of the eater came forth meat," out of the deadly jungle has come forth life and civilisation. Every acre under coffee represents at this day, to take a very low average, not only food and support for one man, but also an annual saving of R20, which he can spend in his own land as he best pleases. Look at Mysore! scarce a decade has passed since her treasury was depleted, her people impoverished, their cattle dead and their seed-corn eaten; now she is rich and prosperous, and her people thriving. Good administration may do much, but the ablest administrator is as unable as the Israelite slave to make bricks without straw. From the sholas of the Nelliampathies and from the forests of the Pulneys, from the hollows of the Shevaroyes and from the hillsides of Peermade, from the slopes of the Nilgiris and from the uplands of the Wynad, from the groves of Coorg and from the "6-arneys" of Mysore, there is flowing, and has been for many a year past, into the neighbouring countries a perennial stream of silver, rich as Pactolus. Unfortunately it is not with this Eastern stream of fable that Government is apt to confound the Coffee planter but rather with the Eastern stream of every-day life which, it is well known, to do most good must be often dammed.—*Madras Times.*

TOBACCO AND COTTON IN DUMBARA.

A correspondent writes:—We have almost got in all our tobacco crop, about 140 acres, a very fair crop indeed, and it is turning out very well in the curing. We are curing for seven other estates and have altogether over 40 tons of tobacco in store! We planted 90 acres of cotton (in one day) in our tobacco fields: it is looking splendid. I shall possibly be able to tell you more about cotton later on, *i.e.* if it pays us; but you see we were able to work very cheaply in having our lines of tobacco to work by and all the land perfectly clear and ready dug for the last crop of tobacco. We planted the 90 acres 3ft. x 4ft., three seeds in a hole, made with a piece of stick with 148 coolies there was no lining or digging to be done. The field of cotton is very regular, one can almost see the plants grow. We have a small cotton clearing at Wategama; that also is tobacco land replanted with cotton—we soak the seed over night, plant the following morning about 1 inch deep and in two to three days after the seed is above ground. Seed from Messrs. Darley, Butler & Co.

THE NEED OF CHEMICAL ANALYSIS IN
THE TEA FACTORY:

TEA-TASTING AND WATER IN COLOMBO AND LONDON.

(By a Practical Man.)

It seems that a necessity for a local chemical analyst to the Planters' Association is beginning to be felt. If there was an "Experiments Committee" of the Planters' Association, it could no doubt find more than enough of profitable work to keep an agricultural chemist going, and perhaps one or two assistants as well, for it is not a great deal that one man can do unassisted.

I do not see that there is much that a chemist could do in the factory, unless he could devise a simple process for determining the exact point at which fermentation should cease.

It would seem as if the process of fermentation at least greatly affected the amount of albuminous matter present, as Dr. Hassall found in black tea 15.55 per cent, and in green tea 24.39 per cent. I have seen other analyses in which the albumen in black teas and in green teas also is set down at very much less than the above. This suggests at least one line of investigation.

With regard to the other subject, viz., the effect of the quality of the water used upon the taste of the tea infusion, I should say the purer the water the better, *i. e.* the flavor obtained will be more entirely that due to the tea. In this respect I think the Colombo tea tasters have a pull over the London men. Of course, if an alkaline substance like carbonate of soda be put into the water, more will be extracted from the tea than by pure water alone, but the neutral salts which occur in natural waters will, I believe, be found to reduce rather than increase the amount of extract. I believe the Colombo water contains a lower percentage of total solids than that of any large town in Great Britain, Glasgow excepted.

Thus we have expressed in grains per gallon the following amounts of total solids:—

Colombo	1.8 to 2.8
Glasgow	1.6
London	18.
Liverpool	6.8
Manchester	4.3
Edinburgh	7.9

If it were a necessity to meet the taste of the London buyers to use water of the same quality as in London, I believe this could be done if we got a full mineral analysis of the London water used by tea tasters. It would be easy then to add the necessary quantity of salts to Colombo water to make it closely resemble the London water.

I have no doubt tea tasters in London use good filters for the water employed in tea tasting. Now a good filter such as Maignen's Filtre Rapide practically takes all the organic matter out of Colombo water, and I think would do the same for London water, leaving only the mineral ingredients to be dealt with.

HATTON IRONWORKS.

Residents in Colombo have only a poor idea of what the Tea Industry is doing for the country and a great number of the people at outstations. It is scarcely realized how great the difference the full preparation of tea on the plantations makes, as compared with coffee which was sent away "in the rough" to be finished in Colombo stores. The quantity of machinery too required for tea is very much greater,

and the activity created thereby is not confined to Colombo machinists, patentees' agents or importers. By no means. There are centres upcountry as full of activity and original work, for the benefit of tea planters as almost any in Colombo. Take the Hatton establishment for instance. How many in Colombo realize the completeness or extent of the Ironworks here: that the workshop alone gives employment to over 100 skilled hands, that beside half-a-dozen lathes of various sizes, four drills, punching and shearing machines, circular and band saws, planing, emery and screwing machines, &c.,—there is a castiron foundry in full operation, and that the enterprising proprietors are at this moment doubling the size of their cupola as they cannot overtake the work with the present one. When this is done, Hatton Foundry will be able to cast single pieces up to 10 owt., a very notable result surely, for a "jungle" foundry in Ceylon.

As regards the work done, it is interesting to learn that among the rest, one tea sifter complete is turned out weekly, and that there are about 100 of these (the invention of Brown, Rae & Co.) now in use. Again, "Souter's Roll-breaker combined with the Hatton Roll-sifter" is in great demand and is considered by very many planters to be about the best machine of its kind. There is a great run on turbine piping just now, the report being that Messrs. Brown, Rae & Co. have orders on hand for over 1,000 feet and as they make every foot of it themselves, casting all the bends, some of them over 2 feet in diameter,—some idea of their busy Works can be formed.

ASSAM TOBACCO.—To the already large list of tobaccos used for cigar wrappers must be added that grown in Assam, both from Virginia and local seed. The quality of both appears to be much the same, and is reported upon most favourably by two wellknown firms, namely, Messrs. Ernsthausen and Co., of Calcutta, and Messrs. Begg, Dunlop and Co., of the Pusa tobacco factory.—*Times of India*, Oct. 10th.

PORTLAND CEMENT FOR SETTING IRON WORK.—A correspondent to an American contemporary has found clear Portland cement to be a good substitute for sulphur in bedding cast or wrought-iron upon stone or iron foundations. It is unaffected by oil, and can be made thick or thin with water as may be required and does not chill upon contact with cold surfaces. Where used to bed wrought-iron beams upon cast-iron column brackets it has been found to answer perfectly, even when not more than an eighth-of-an-inch in thickness.—*Indian Engineer*.

Speaking of PEANUTS, it is astonishing how this article is coming into a variety of uses. In the United States it is largely eaten in the roasted state, and much enjoyed. It abounds in oil much resembling olive oil, and which can be used for similar purposes. The best peanuts contain 50 per cent. of this colourless oil, which is obtained by cold expression. Hitherto the chief use for peanut oil has been in soap-making. The nuts are also dried and ground into flour, out of which a very palatable kind of biscuit is manufactured. Recently peanuts have been roasted and used in the manufacture of chocolate. In their roasted state they are also used for coffee. In their natural condition the niggers crush and ferment them, and thus obtain a cheap drink. The peanut is said to be a very easy plant to raise, and the stem and branches are a highly acceptable fodder for cattle. The demand for peanuts has been trebled within the last three years, and although more than three millions of bushels are raised annually, the supply is not equal to the demand.—*Dr. J. E. Taylor, F. L. S., in Australasian*,

MEMORANDUM REWEIGHTS OF TEA.

[Messrs. George Stuart & Co. are good enough to write to us as follows:—"At Messrs. Arbuthnot, Latham & Co.'s request, we beg to hand you one of their circulars in connection with tea packing and weighing, which may interest your readers if you care to give it space in your paper."]

To ascertain the nett weight of imported tea for purposes of duty and of sale one of the three following methods has to be made use of:—

1. Average Netting
2. " Taring
3. Actual weights

1. Under the first method "average netting" the system is as follows, viz: Each package in the parcel is weighed gross, as landed, then the Customs officer selects from the whole parcel 10 per cent of the packages (but never less than 3 chests), comprising the highest, lowest, and average gross weights. The contents of these packages are then turned out into bags of equal weights, and weighed, and the average struck, such average being taken as applying to each package in the break, except any be broken or evidently deficient in quantity, when they are turned out and the actual nett weight allowed. In nett weighing, a package must actually draw the weight in the scale, thus 50 lb. 15 oz. would be called only 50 lb. equally with 50 lb. 1 oz.

2. Where on account of inequality of nett weights it is found desirable rather to take an average tare; than an average nett, the system is somewhat different from the foregoing, thus. Each package is weighed gross as landed, then certain packages are selected by the Customs according to a recognised scale sanctioned by the Board of Trade. These packages, which must be sound and entire, are then very carefully emptied and the wooden cases with the internal lead weighed. The average of these weights being struck, such average tare is taken as applying to the whole break; in the same way as in netting. In taring there must not be more than two pounds difference in the tare of any two packages, or an average will not be allowed and it is the rule to take any odd ounces as another pound; thus 15 lb. 1 oz., 2 oz., or any other number of ounces less than 16 lb. would be called 16 lb.

3. Whenever it is necessary on account of uneven net weights, or uneven tares, or irregularity of quality to bulk on this side, the contents of every chest are turned out, carefully mixed on the floor, and then refilled (the different breaks being treated separately) each chest is weighed separately empty and full,—the difference between the tare and gross weight giving the "nett." The Customs officer in making the tare takes any odd ounces as another pound, but in fixing the gross weight disregards the extra ounces.

So far as net weight is concerned "average netting" is decidedly the best system for the importer, for he can in most cases obtain total invoiced weight, and, sometimes, even more. It is less expensive, and it has the advantage that the tea is not so much handled on this side.

Average taring has the same advantages as average netting, except that under this system the weights do not turn out so favourably to the importer.

Whenever unevenness of quality makes bulking necessary the third system "actual weights" must be adopted. It is more expensive by about $\frac{1}{3}$ d per lb. on chests than "average taring," and its only recommendation is that there is practically no risk of rejection by buyers of a break after sale on the ground of inequality.

The system of "average netting" has, for the present, had to be abandoned, as the greater number of the dealers will not bid for tea so put on the market, and the competition of the remainder is not sufficient to enable an importer to secure the full value of his tea.

Therefore it is desirable, where possible, to adopt the second method;—for this purpose it is necessary.

a. That each break be perfectly regular throughout in quality and character.

b. That the tare (i.e. weight of empty package, nails etc.) of each chest throughout each break be "even,"

so far, at least, that there is not a greater difference than two pounds between any two chests.

Whenever for any reason it is not practicable to ensure the regularity of the tea, or the evenness of the tares, it is then to the planters' interest not to bulk abroad but to pack their tea as it is ready, for, if both the above conditions are not strictly observed, it becomes absolutely necessary to bulk at home, and to take the nett weight by system No: 3, that of "actual weights."

JAMAICA, Sept.—Mr. Wm. Sabonadière writes:—"We have had such wet and windy weather since March, that the crops from the *bona fide* Blue Mountain properties cannot be large: it has prevented heavy blossoms."

TOBACCO IN JAMAICA.—The latest *Jamaica Gleaner* to hand (Sept. 11th) has an article bewailing the falling-off in tobacco culture and manufacture in Jamaica and that in the face of English capital pouring into Cuba. The following series of causes of failure may be instructive as warnings to Ceylon planters:—"The first of these causes is want of care in the selection of ground. The second is the lack of skilled labour in attending to the young plants and throughout the period of growth. Third the want of attention, care and skill in the preparation of the tobacco and in the selection of the leaves, the period of cutting, and finally, in the manufacture into cigars, and the careful grading of *size, quality and color.*"

COFFEE PLANTERS will entertain feelings of the deepest affection for a compound known in America as "Hillis's plantation coffee substitute." It is described as "in fact, a native coffee, being virtually a compound of vegetable substances, combining all the concomitant ingredients of the imported berry." In respect to the inventor of this precious substance, it is stated that after "years of research and experiment, he discovered substances which, when submitted to entirely new processes, produce an article which, in its granulated form, is similar to Java coffee, and vastly superior to a large proportion of the coffee now used in this country, the only property wanting being the caffeine. The ingredients used are healthy, invigorating, and nutritious." No doubt coffee planters would like to confine the inventor to a diet of this stuff for a time, and ask him to report on it after a prolonged trial.—*H. and C. Mail*, Sept. 27th.

THE COCONUT BEETLE PEST.—A correspondent writes to us:—"In your issue of yesterday you give an extract from the *Straits Times* regarding the Coconut Beetle. That these Pests are known in this Island may be gathered from the fact that so long ago as 1864-5, a premium was paid on Induranawella Estate for their capture and destruction. This property, situated about 16 miles from Galle, then belonged to Mr. John Sonenkalb, Merchant, and was a large one planted up entirely with coconuts. It was managed by Mr. Jan Kap, another German, and had steam machinery for the manufacture of coconut oil. A number of toddy-drawers were entrusted with the work of capturing the beetles, which were to be seen suspended every morning to the ends of the branches of trees on either side of the estate road, over which the Superintendent went his daily round of inspection. At first I could not understand this curious sight, but was told on enquiry that the beetles were thus left to be counted, as payment was made per head. It is to be hoped that at no time will Ceylon require its Legislature to aid in the extermination of the coconut beetle. While on this subject, I may mention, that it appears to me the coconut trees growing on the south side of Colombo have a great enemy in rats, which eat through the fruit when it is tender. From what I have seen, in some gardens about 25 per cent of each tree are sacrificed to these greedy vermin, though, I am told the remedy is simple."—*Local "Times."*

COFFEE CULTIVATION: REPLANTING OLD COFFEE FIELDS AND THE ADVANTAGES OF SHADE.

We draw attention to the long and interesting letter in which Mr. J. P. Hunt of Coorg, an old and experienced planter, whose name has long been favourably known to us, gives our planting readers, the results of a variety of experiments in replanting old coffee fields with coffee and a large amount of information in respect of shade and shade trees. We have, no doubt, that the letter will be read with much interest by many mercantile agents and planters. What is said about the successful renovation of old coffee fields in Mysore is especially interesting. In Ceylon we used to talk of forty years as practically the age of the average coffee bush and though, alas, a great many proved useless for cultivation long before that age, under favourable circumstances not only in Haputale and Badulla, but in the Kandy districts, up to the time when leaf disease fully developed, there were coffee trees 40 years old, which though systematically cultivated and cropped every year, gave no sign of want of vigour and looked as if they would go on for another 40 years. But *Hemileia vastatrix* changed all that prospect, and though in Uva especially, we have still some old coffee fields in cultivation, yet, altogether the area of an age to warrant an experiment in replanting, is not very extensive. The major portion of the coffee cultivated in Ceylon at present said cannot be to be suffering from the age of the trees. Nevertheless there are fields on which, if there were sufficient warrant for successful results, the experiment might well be tried, while many abandoned acres not yet in tea are still available. But even with a change of seed—with the use of the carefully selected Nalkanad-Coorg seed, which Mr. Hunt offers to supply,—the question will be raised here,—have we not had sufficient proof that no new coffee clearing is likely to succeed beyond giving a very few crops in Ceylon? Even on virgin forest land and with, we believe, Coorg seed, a clearing has been found so affected with leaf disease as to prevent any crop being gathered larger than 3 cwt. per acre. We put these facts prominently forward, because we have no desire that there should be any blinking of the risk run, while, nevertheless urging, that a fair trial has yet to be given here to shade cultivation with fresh seed, and after the fashion which is still successfully pursued in Mysore. It is possible that there have been such local experiments—suitable shade trees being grown simultaneously with the coffee—without our having heard of the results. And this leads us to express the opinion that the present would be a favourable time, for the Planters' Association to endeavour by means of a special sub-Committee to draw up a report on coffee cultivation and specially on young clearing experiments (if any) as carried on since the great collapse in our coffee crops six years ago, sent nearly every planter to seek relief in "tea." The Committee might well take cognizance of the attempts made for ten years back to check or prevent the threatened doom of our staple. The history of any clearings opened with coffee since 1878 could not fail to be instructive, and in some cases at least, we should hear of trials with Coorg, Mocha and even West Indian seed, apart from "the rush" into Liberian coffee. It is possible too that there may be information available about shade in connection with one or other of these experiments; and, in any case, the Committee might be asked to give its opinion as to the wisdom of making further

attempts to replant, or plant anew, coffee in Ceylon, with Coorg seed, and after the Mysore fashion. It would then be for individual proprietors or planters to follow, or not, the advice in such Report—a Report which would be certain to attract a large amount of attention both in and out of the island. With coffee at the present very high prices and no sign of the supply becoming equal to the demand, and moreover with the Coorg and Mysore planters still planting and cultivating successfully, it may well be thought that something ought to be done with coffee still in Ceylon and more especially in the Uva districts. New clearings, if such were formed now, would come in for the benefit of railway transport for fertilizing substances as well as for other articles.

BLUE GUM TIMBER FOR TEA BOXES?

We are indebted to Mr. E. Gordon Grinlinton for a sample piece of blue gum timber from a six year old tree cut down on September 1st. The tree was 50 to 60 feet high and at 5 feet from ground 30 inches in circumference—being a smaller tree however than the average of the same age. The piece sent to us is a very clean piece of wood 40 inches, $2\frac{1}{2}$ by $1\frac{1}{4}$ inch tapering in width, and about $\frac{1}{2}$ inch thickness, and has not the slightest smell or taint. Mr. Grinlinton, senior, in sending us the sample from his son, is good enough to write:—"I asked for it to send you, as I thought from the light weight of the wood and the absence of all smell of turpentine that the wood might be used for tea boxes. I think of having two boxes made and packed with tea, lead-lined as usual, so as to try in London if the wood will suit. If it does, as I think it will, blue gums planted on our patanas will keep Ceylon in boxes for all time."

In this connection, we may refer to the recent splendid prices obtained for Portswood tea at the sale of 24th Sept., 2s 6d for broken orange pekoe and broken pekoe, and an average of 2s per lb. all round for all three grades, orange pekoe, pekoe and pekoe souchong. In Portswood Factory the machinery is now all at work: 3 rollers and a desiccator being driven at the same time, by one 20 ft. water-wheel.

PEPPER CULTIVATION AND POSSIBLE PROFITS IN CEYLON.

Writing in reference to a paper on Pepper Cultivation in the *Madras Times* which we submitted to him, Mr. W. Jardine says:—

Many thanks for sending me the paper on pepper cultivation. It is interesting and will bear reproducing in the *T. A.*, though there is nothing new in it or that you have not got embodied in your paper on Pepper in "All about Spices." *Dadap*—the variety without thorns—would answer better for standards for the vines than *Erythrina*. When the standards are a few years old they require almost yearly thinning to regulate the amount of light necessary, and only those who have had experience of it, know the great annoyance and worse, the lopped branches of the *Erythrina* are. It is almost impossible to move off a road, and to the bare-footed and bare legged coolie it is simply torture. The *Dadap* too gives a more checkered shade, and at no time of the year is it quite bare of leaves. As to yield I am not yet in a position to say from personal experience what the vines over a large acreage would give. Individual vines do often yield large crops. One vine I know of, now about 10 years old, gave two years in succession 40 measures of green fruit, which when dry gave 10 measures of merchantable pepper, which sold for R4.50. If every vine were to yield at this rate an estate of 100 acres would be a princely property; for at 300 vines to the acre it would mean R135,000!

Taking however the yield at the moderate rate of 50c. each vine it would still be a handsome income. I believe there is a good future for pepper in suitable localities.

UPCOUNTRY PLANTING REPORT.

THE ANONYMOUS LETTER SEASON—A SAD RECORD OF FALLEN HUMANITY—A THING WORTH LOOKING INTO—CACAO AND BORER—COTTON AND THE NATIVES—DETRIMENTAL WEATHER TO TEA AND REDUCED RETURNS—HORNETS AND DR. WILSON OF BOMBAY—A MORAL.

October 17th.

When the cherry tends to ripen on the COFFEE bush, and a watcher is put on, the anonymous letter season begins. You may be as particular as you like regarding your choice of watchmen: institute inquiries in numerous quarters; interview many applicants, and select the best man that can be had for the 12-50 a month; but when all is done you very soon learn through the medium of the anonymous letter that your choice is not only a bad one, but could hardly be worse. From the date the man enters your service his true character is revealed. Without experience one could never have anticipated the interest which a certain class of the public take in these humble appointments. The unselfishness of their representations, when they address you as "Honored Sir" and are too modest to sign their names, is seldom approached. I have before me at present one of these precious documents, and it is quite touching to see running all through it a strongly expressed desire that I may be saved from the folly of keeping my present watcher. "The man is unfit for the watchership, especially on an estate as this," is what I am told, "it is far better if a cooly be employed!" The villain who has imposed on me is a proper one: and his life-history, which my anonymous correspondent supplies, is a sad record of fallen humanity. He was a Fiscal's peon, but, being found guilty of embezzlement, was dismissed and imprisoned. When he got out of gaol, he committed theft again, and was imprisoned a second time. He is a gambler and a drunkard, and a man with many an alias. Not content with two wives, and two children, he has added to his responsibilities by running off with another man's wife. Here my correspondent pauses, he has more agony yet to pile, but confidently awaits the effect of what has already been disclosed: "I think these facts are quite sufficient," he says, and I think so too, and this is how he ends:—"Therefore I beg most humbly and earnestly that it may please you to appoint another person and to send away this unworthy jail-bird. I hope I shall not be forced to write you concerning this trifling thing further or to trouble you, and to spend my precious time in regard to this vagabond." Who are these people who take such a loving interest in our affairs? and how is it that every year when the watcher is appointed they should feel constrained to write? Who pays for the paper and the stamp, not to speak of "the precious time"? This is a subject worth looking into; but it is easier to ask questions than to answer them.

The CACAO crop is beginning to ripen but the ravages of the borer are too manifest in the large percentage of damaged pods which the coolies bring in. Of course there is always a bad start, at the opening of the cacao harvest. But the one this year seems to be worse than usual. Still the promise is fair, and the trees look well.

The abnormally wet season has I regret to hear ruined the CORRODOP. This is very unfortunate

as far as the native is concerned, for he has neither the pluck nor the energy of his European brother, and a new product that starts badly is heavily handicapped for the future. The European may draw encouragement from a reverse; but the Sinhalese villager is not in the habit of wringing fortune from misfortune and not likely to begin on cotton. It is strange how different is the opinion of men travelling over the same ground in regard to the interest which the Sinhalese have taken in this new product. One man got quite enthusiastic and hopeful in talking with me about cotton taking the place of coffee in the villages, and wherever he went in his itinerating life he was aiding in the distribution of cotton seed. The other who worked the same ground saw in what was being done only the headman's influence, and that again was derived from the Kachcheri. He had little hope of cotton enriching the impoverished villager. It is an uphill work getting the Sinhalese to leave the beaten pathway of their fathers. What has come of the effort to introduce Liberian coffee among them, and especially cacao? This latter wanted little trouble or expense to cultivate; and in the sheltered villages where could better land be had for its growth? But spite of all these advantages the effort to have it taken up has failed. Is cotton ever likely to do better? A plant that gets ruined in the wet, and is devoured by insects when the weather is dry, may suit a European with surplus energy, but how about the villager? Is the man, who during the hot months allows his vegetable plot to go to ruin, rather than water it, likely to go poochie-hunting among his cotton plants? or take any trouble whatever? Here, as in other things, we want men of large faith to see in the dry bones of the apathetic and enervated villager the possibility of a future energetic and pushing man.

The wet and cold has been bothering us all sadly, checking the TEA flush, and reducing the returns. With fine prices which at present obtain, we could well afford to have better weather, and would not grumble if it were hot.

I notice the senior Editor, in his letters "from the hills," is interested in HORNETS. It is only this year that I have seen them in any numbers here, and they are such ugly customers that war is waged against them. Their nests, which they build on the tea, and which grow in no time to a considerable size, are destroyed at night, a promise of twenty-five cents, *cash down*, being sufficient to effect the service. The ruined nest to be produced at morning muster. Dr. Wilson of Bombay you will remember was nearly killed by an attack of hornets, and he used to say that the painful experience threw a *wonderful* light upon the text, "They compassed me about like bees." If the science of exegesis demanded from all an education of this kind we would have better sermons from our pulpits, and fewer theologians out of them. Moreover it would have a marked effect in settling the unsettled. Creeds would then last for all time.

PEPPERCORN.

HILL COUNTRY PLANTING REPORT.

THE RAILWAY FIRE WOOD SUPPLY AND RE-AFFORESTATION—WANTED A CHEAP FUEL SUBSTITUTE—WATTLES AND BLUE GUMS—OTHER TIMBER TREES—ORNAMENTAL TREES TO BE PLANTED ALONG THE LONGDEN ROAD AND IN NUWARA ELIYA—EFFECT OF THE SOUTH-WEST WINDS ON GROWTH OF TREES—FRUITING OF AN ENGLISH OAK-TREE IN CEYLON.

NANUOYA, Oct. 19th.

I have now ascertained that the jungle on the right-hand side of the Longden Road, between Nanuoya and Nuwara Eliya, which is in course

of clearance and re-afforestation, yields on an average 120 yards of firewood per acre, beside some shingles. The wants of the railway up here, in the shape of wood fuel, amount to the yield of 5 acres per mensem, or 60 acres per annum, a quantity which will be largely increased when trains are running to Haputale. At this rate of consumption, it is obvious that very large expanses of jungle reserves will be necessary, and will in a few years be used up, if a cheap substitute, in the shape of the residuum of petroleum, coal dust, &c., cannot be rendered plentifully and cheaply available. Not merely for the sake of the cheap working of our railways, but for that of expanded planting enterprise along the line of the section now being constructed (much of the soil being excellent), it is greatly to be wished that a good and cheap fuel substitute may be discovered. Meantime the Forest Department, while supplying the present wants of the railway in the shape of firewood, are providing for future demands for both timber and firewood by planting, at the rate of 1,200 trees to the acre, blue gums (*Eucalyptus globulus*) and wattles (*Acacia decurrens*) in the proportion of two of the former, grown for timber as well as firewood, to one of the latter, which is relied on for firewood alone. The wattle chosen, out of those which have been naturalized in and around Nuwara Eliya, is that which many have been in the habit of regarding as "the golden wattle," *par excellence*. In profusion and beauty of golden-coloured blossoms, it excels the other prevalent species, *A. dealbata*, the blossom of *A. melanoxylon* not being conspicuous in Ceylon. There is a rich, dense grove of *A. decurrens* near the church, at Nuwara Eliya, which, arching across the road, yields a grateful shade when the rays of the sun are most intense. Firewood alone being in view, there can be little room for doubt that the choice of *A. decurrens* has been well advised. But I feel bound to say, as the result of very large experience on Abbotsford estate, that I cannot say the same for the blue gum in this region. Out of a large number planted, there are, in favourable circumstances of soil and shelter, some splendid trees. But on ridges and hill-faces exposed to the wind and rain of the south-west monsoon, they shoot up thin and with scraggy foliage at the tops. Such characteristics distinguish blue gums, exposed as I have described, not only here but all over Upper Dimbula. So with blue gums planted on the portion of Baker's Farm exposed to the south-west monsoon. In Nuwara Eliya itself and at Kandapola, where there is shelter from the south-west, *Eucalyptus globulus* has grown not only rapidly (its great merit) but of noble proportions. Planted in great numbers and so close together as six feet apart only, the trees may support each other and resist the weather; but I feel bound to state that, except in the special cases mentioned, the blue gum is the least satisfactory of the many we have grown here, close to the scene of re-afforestation. The red gum (*E. rostrata*) does not grow quite so rapidly and is not so uniformly one-stemmed, but it stands exposure better, and its red-coloured timber is very superior. It grows specially well along the banks of streams. Still more successful with us have been the Australian mahogany tree, the true jarrah (*E. marginata*) the fine qualities of the timber of which are too well known to need description. It is not so rapid a grower as the blue gum, but with us it has made very good progress. Still more successful has been a tree which resembles the jarrah in stoutness of stem and umbrageous habit, *E. robusta*, of which we have very noble specimens. Von Mueller says of

this species that "It attains a height of 100 feet and a stem girth of 12 feet, bearing a really grand mass of foliage. Resists cyclones better than most of its congeners. The wood is remarkably durable, reckoned a fairly good timber for joists, also used for, ship building, wheelwright's work and many implements, for instance such as mallets." Maiden gives a longer description of this red- or brown-coloured wood, rendered durable, it is believed, by the presence of kindred. It is prized for building purposes and seems equally good for railway sleepers and firewood. In its native habitat it flourishes specially in swampy ground, but in our wet climate it grows splendidly on the tops of ridges. But perhaps the most remarkable of our eucalypts for rapid and luxuriant horizontal growth of branches, each of which is equal to a tree stem, the whole covered with a magnificent mass of minute dense drooping foliage, is *E. pauciflora*. Some specimens, not yet ten years old, by the side of the road which winds through Abbotsford, up one side, of the river and down the other, are objects of wonderment for the enormous size of the stems and branches and the red colour of portions of the bark, contrasted with white in other. In Australia white prevails. Von Mueller states: "It attains considerable dimensions, grows best in moist ground, [our climate supplies this conditions.] ascends to alpine elevations, and thus is one of the hardest of its congeners. Horses, cattle and sheep browse readily on the foliage. It is locally a stand by in bad pastoral seasons. Its timber is used for ordinary building and fencing purposes. For quickly producing fuel one of the best of trees." It would, therefore, be one of the best to cultivate for railway and tea estate purposes. There are other splendid timber trees, which, after they had attained considerable dimensions, we have felt compelled, though with many a pang, to cut down, owing to their injurious effects on the tea plant. Amongst them is that most valuable timber tree, *A. melanoxylon*. So with the grand *E. amygdalina*, which grows to be the tallest tree in the world. It is remarkable for its bark of a marble whiteness, and specimens which we have spared are very handsome. Von Mueller writes: "The wood is fissile, well-adapted for shingles, rails, for inner building material and many other purposes, but it is not a strong wood." This tree yields from its leaves the finest eucalyptus oil, in largest proportion, nearly 3½ per cent. The timber of this species, variety *regnans*, was declared by the Victorian Carriage Board to be second only, if second, to blackwood (*A. melanoxylon*) for railway carriages, so that strength cannot be wanting. We have a few specimens of *E. leucoxyton*, one of the two iron-bark trees, which yield about the most valuable timber which can be grown, being almost unsurpassed for strength and hardness. We have also some fine stringy-bark trees, *E. obliqua*, the young trees of which in Australia are sometimes used for telegraph posts. It grows 300 feet high and yields a great bulk of wood useful for ordinary purposes, shingles, rails, &c. Amongst our many eucalypts is also numbered *E. longifolia*, which grows to a height of 200 feet with a great girth of stem. "Mr. J. Reader asserts that there is not extant a more useful timber; it stands well in any situation." There are other eucalypts which we have not identified, and amongst our recent plantings for timber and firewood in the future, with *Cedrela toona*, *Cryptomeria japonica* (both most promising), frenalas, cypresses, &c., we are trying the valuable red-timbered *E. diversicolor* which converted into railway sleepers can scarcely be dis-

tinguished from jarrah. A trial of some, from Western Australia, supplied by Mr. Davies of Adelaide, has been made on our sea-side line. Compared with the poor sleepers made of Norway pine, they looked splendid. Most amusing errors have been made, by confounding this eucalypt, the native name of which is *kari*, with the splendid New Zealand *kauri* pine. So far has this gone that in a list prepared some time ago by a forest officer, he astonished some readers of the *Observer* by describing the tree as both a *eucalypt* and a *pine*, a conjunction as impossible as that of an oak and a larch. Allied to the eucalypts in appearance we have got an exceedingly handsome and very valuable tree, which grows to 200 feet and yields excellent timber, *Synocarpia laurifolia*. Of casuarinas we have many species, all most valuable for firewood, while some yield excellent timber. Last, but not least for present mention, is *Grevillea robusta*, beautiful in fern-like foliage, and comb-like golden flowers, while its timber, used in Australia for tallow casks,—is most valuable. It is now a great favourite, from Colombo up to Nuwara Eliya, and justly so. The leaves it sheds fertilize the ground, and the branches, trimmed off as the tree grows, can be used as fuel. Having noticed the confounding of a eucalypt with a pine, I feel bound to correct the idea which I shared with others, that the wattles naturalized at Nuwara Eliya included, beside *A. melanoxylon* (a beautiful and valuable tree, liable to be infested by the parasite, *loranthus*), three others,—*A. decurrens*, *A. dealbata* and *A. pycnantha*. The latter, "broad-leaved wattle" has been only recently introduced. I saw a few plants of it in Mr. Whyte's gardens, and more are growing in the Local Board nurseries. But what we have hitherto regarded as the true "golden wattle," being now established as *A. decurrens*, it would be interesting to be assured which of the other species or varieties growing on the Plain is *A. dealbata*. Of the two longest established, one is a poor scrubby bush, which ought not to be encouraged. The best species for firewood ought to be introduced and cultivated by the Local Board. I may mention that on my own portion of land near the Bund, the toons (deciduous plants, naturally) growing at the end facing the south-west monsoon became recently bare poles. They will soon recover, however. On the other hand, the cryptomerias, which, now that hares and rats cannot reach their tender tops, are shooting up luxuriantly and promise exceedingly well, seem to have scarcely suffered at all from the weather. In July there was a good deal of red in the foliage, but now all is beautifully green. Dr. Trimen feared that our climate would be too wet for these trees which are really pines; but as yet, at the age of over three years, they look specially flourishing. For a part of our trip yesterday, we had the pleasure of the company of Mr. Armitage of the Forest Department, from whom I derived the information regarding re-forestation. He added that various ornamental trees would be planted near Nuwara Eliya and by the edge of Longden Road. I wrote on a former occasion about comparatively bare or rather dwarfy spots in the upland forests, where chensang never could have taken place. I attracted attention to the fact that such spots were chiefly on steep declivities, exposed to the fury of the south-west winds. Mr. Armitage added that sometimes a group of keena trees over-topped the rest of the forest, stood the exposure for a time, and then died off. The Forester also mentioned the utter absence on the eastern side of the dividing range of the nilu undergrowth and madul and other trees so prevalent in the forests of western exposure. Our own observation on the

patanas showed how local some forms of terrestrial orchids and other wild flowers are.

P. S.—I have to record an event which I suppose is unprecedented in Ceylon, the fruiting of a genuine English oak-tree. Some time in 1874, I think,—certainly not earlier,—Mr. Cunningham on Glencairn estate, Dikova, presented me with a couple of oak plants, which at an elevation of about 4,700 feet have flourished and, under the influence of judicious pruning, have become very handsome trees, about 25 feet in height. Mr. John Fraser brought up a branch with beautiful foliage from the lower bungalow today, and announced that the tree from which it had been cut had borne some acorns. They are but babies as yet, but we trust they will mature and produce Ceylon-born oaks. Dr. Trimen and Mr. Nock will know if there is any record of an oak at Hakgala or anywhere else in the island having produced acorns. If there is no such record then I claim for Abbotsford all the credit which may be due for such an interesting event, which Dr. Trimen will doubtless think worthy of mention in his next report. Ceylon, less favoured than Java, can boast of no indigenous oak, for "the Ceylon oak," so-called, resembles the oak only in foliage. But Java is supposed by Wallace to have once been connected with the Himalayas, which are rich in oaks and elms.

PLANTING IN BORNEO.

(From the *British North Borneo Herald*.)

OCTOBER 1ST.

The Government is in correspondence with Government of Bombay with a view to importing all the emancipated slaves who are released in that city by H. M. Ships as it is understood that being ignorant of both English and Hindustani they are unable to find employment in India where they have recently been arriving in large numbers.

We are glad to hear that the Estimate of \$200,000 on account of Land Sales has already been exceeded by \$4,708 the amount received in August was \$61,912, and the total to date (31st August) \$204,708.

Several batches of Sulu ponies have arrived in Sandakan lately for the most part very fair specimens of horse flesh. They have been eagerly bought up, with the result that pedestrians are becoming uncommon, nearly every traveller being mounted to take the morning and evening air.

The following gentlemen have been appointed Visiting Justices:—Mr. Robertson, Mr. H. Wilker, Mr. H. B. Dunlop, Dr. Walker, Principal Medical Officer has been appointed a Visiting Justice to the Gaol and Captain Beeston Police Magistrate a Visiting Justice to the Hospital.

The wild boar season appears to have set in, more especially on the Kinbatangan and Segaliud Rivers. Mr. Fryer and Dr. Rigby have had some sport in this direction on the Kinbatangan, the Amazon of the territory. Mr. Johnston of the Segaliud reports them in great numbers near his tobacco plantation. A few days ago the Melapi Estate police were out in the jungle near the estate when they came across several elephants. They wounded one bull, but he managed to get away with two balls in the stomach. On the Segaliud just now the elephants appear to have vanished for a time.

PLANTING IN DARVEL BAY, BORNEO.

The tobacco crops are looking exceedingly well on both estates and the planters look forward to far better results than they hoped for a short time back.

The experimental gardens in Silam are looking very pretty and there will be a fine crop of coffee this year. There are quantities of young plants of all sorts to be had at absurdly low prices and it is a pity that this is not more generally known.

Two prospectors who were sent to look for gold returned after six days absence in Sungei Pakat and Sungei Munsad. The sample from the latter river was similar to the gold brought by the gold party from Segama whilst the sample from Sungei Pakat was like a very fine powder mixed with a black sand of a great fineness.—*British North Borneo Herald*, Oct. 1st.

RABBITS FOR THE NILGIRIS.

(From the *South of India Observer*.)

We have already mentioned the fact that some seventy rabbits have arrived from Australia for the purpose of being let loose on the Hills.

A more ingenious device for worrying the already sorely beset planters could not well have been conceived. Surely the man to whom occurred the above atrocious idea must have been bereft of his senses. The fearful example of the abandoned lands in Australia, and the enormous amount expended to put down the fearful rabbit pest seems never to have been read by him, nor could he have ever calculated the number of rabbits produced by a single pair in the course of few years and yet we are to be cursed with over thirty pairs! Even in England where the population is far more dense and the price obtained for rabbits very remunerative, there is considerable difficulty occasioned in keeping them within bounds. Rabbit proof wire netting is everywhere advertised: can it be that the above atrocious suggestion is the emanation of somebody interested in wire fencing! Or is it as food for the Jackals that some enthusiastic Jack hunter's mind gave birth to the horrid conception! Let once the rabbits get a fair hold of the country, and good bye to tea, coffee and cinchona and firewood plantations; to say nothing of orchards. Rabbits not only graze down all green produce, tainting the land to such an extent that cattle will not feed after them on it, but they bark trees by hundreds and thousands in the most mischievous manner, not even sparing the Scotch fir!

We say a Meeting of the Game Association should at once be called to reconsider this most serious matter. In a thinly populated country like India, it will be impossible to keep down the increase of the rabbits, and at present the Burghers have as much as they can do to hold their own against wild pigs and hares, which latter have greatly increased under the protection of the Game Act: no less than eight were seen at one time by a planter strolling over his own field in the Burgher country is not this proof that they can increase in security? What more is wanted for the rabbit? And if the Burghers have this added pest to their other burdens, it will not be surprising if one fine day they resolve to abandon the villages and migrate to Mysore. Already they bemoan their hard fate, with uncertain monsoons, short crops, and the inevitable tax collector, to say nothing of the yearly deteriorating soil. It will take now only the rabbits to add the last straw to their burdens. Should the Burghers go, then the Collector may pack up his portmanteau and follow. So serious do we consider the matter that should the Game Association be unwilling to reconsider its action, we think that Government should interfere. It were far better to let loose a few tigers than the aforesaid rabbits: the former would kill a few head of cattle and then the gallant members of the Game Association would kill them and there would be an end of it; but who shall kill the rabbits! They have been powerless to do it in Australia though hundreds of hunters have been let loose on them to shoot, trap and poison; and finally a reward of £20,000 has been offered to anyone who can invent a plan by which to stop this scourge. In the hopes of gaining this splendid sum the all conquering Pasteur came to the rescue, and suggested his infallible (?) plan, which alas! like all the rest has proved a failure. The above well known facts stare us in face, and yet in spite of this dire experience there has been found a man, or men,

capable of introducing a plague which has depopulated vast areas of country and ruined thousands. There is a story current that rabbits once sunk an island.

Forest officers will have a fine time of it: they will have nothing to conserve, if goats be bad, rabbits are fifty times worse. It will not take many years for the Forest Department to have nothing left to conserve. If goats could destroy the Forests of St. Helena; what cannot rabbits effect? Rabbit proof fencing answered very fairly in England, but in this country who can afford it in the first place, and in the second the same results will follow as in Australia, where the rabbits simply burrowed under the fence and came through the other side because there was nothing left to eat on the outside! We have heard of many mad schemes in our day, but this is by far the maddest of them all!

A Ceylon contemporary thinks the rabbit has too many enemies in India, to permit it becoming the plague it has been in Australia, and that probably it will be kept under, if not destroyed by these hostile factors. It may be so; but suppose this does not prove the case? Why hazard the introduction of a course on the probability of its not proving such? [Rabbits, it seems, have already been let loose more than once in the hill country of Ceylon, and have never been seen again: their enemies are too numerous for them to multiply as in Australia.—ED.]

THE RUBBER TRADE in Pará appears inclined to demand a share of the aid so generously extended to agriculture by the government in other parts of the empire, and the demand is just. Business is evidently in a very unsatisfactory condition at Pará.—*Rio News*.

CHINESE FLOATING GARDENS.—In a recent number of the *China Review* Dr. Macgowan describes the manner in which floating fields and gardens are formed in China. In the month of April a bamboo raft 10ft. to 12ft. long and about half as broad is prepared. The poles are lashed together with interstices of an inch between each. Over this a layer of straw an inch thick is spread, and then a coating two inches thick of adhesive mud taken from the bottom of a canal or pond, which receives the seed. The raft is moored to the bank in still water, and requires no further attention. The straw soon gives way and the soil also, the roots drawing support from the water alone. In about 20 days the raft becomes covered with the creeper (*Ipomoea reptans*), and its stems and roots are gathered for cooking. In autumn its small white petals and yellow stamens, nestling among the round leaves, present a very pretty appearance. In some places marshy land is profitably cultivated in this manner. Besides these floating vegetable gardens there are also floating ricefields. Upon rafts constructed as above weeds and adherent mud were placed as a flooring, and when the rice shoots were ready for transplanting they were placed in the floating soil, which being adhesive and held in place by weed roots, the plants were maintained in position throughout the season. The rice thus planted ripened in from 60 to 70, in place of 100, days. The rafts are carried to the shore, floating on lakes, pools or sluggish streams. These floating fields served to avert famines, whether by drought or flood. When other fields were submerged and their crops sodden or rotten these floated and flourished, and when a drought prevailed they subsided with the falling water, and while the soil around was arid advanced to maturity. Agricultural treatises contain plates representing rows of extensive ricefields moored to sturdy trees on the banks of rivers or lakes which existed formerly in the lacustrine regions of the Lower Yangtze and Yellow River.—*London Times*.

Correspondence.

To the Editor.

THE SUN SETTING LEMONGRASS ON FIRE.

DEAR SIR,—I beg to enclose a cutting from "Tit Bits" Inquiry Column of September 7th, and shall be glad to learn whether you or any of your readers can verify the statement about the sun setting fire to the lemongrass. I have had several years' residence on the Kandyan hills, but no such occurrence has come within the range of my experience, nor do I think it probable in a country where paddy-straw is the usual material for thatching native houses.—I am, dear sir, yours faithfully,
LEMONGRASS.

"3830. Do the rays of the sun ever set fire to natural substances without the aid of a burning glass? In desert and tropical regions, this more or less frequently occurs, as there the earth gets the full direct power of the sun, with the result that everything becomes dried up and heated till it is like tinder, and ready to burst into flames on the slightest provocation. In Ceylon the sun frequently sets the lemon grass, which grows on the Kandian Hills in that country, in a blaze. A peice of phosphorus when moderately heated in the air by the sun will take fire."

[We certainly never heard of the sun setting lemongrass on fire in Ceylon, nor is such a statement made by Tennent or any other of the writers on Ceylon so far as we can recollect.—ED.]

COFFEE PLANTING UNDER SHADE:
A COORG PLANTER ADDRESSES HIS
CEYLON BRETHREN:

COFFEE PLANTING EXPERIENCE OF 29 YEARS IN COORG AND MYSORE—PLANTING OF COFFEE IN THE OPEN AND ITS UPKEEP—SOUTHERN INDIA v. CEYLON—REPLANTING OF OLD ESTATES WITH COFFEE SUCCESSFULLY TRIED—SYSTEM OF SHADING PRACTISED IN MYSORE AND THE PLANTS MOST SUITABLE FOR THE PURPOSE.

Mercara, Coorg, October 5th, 1889.

SIR,—The question of introducing into Ceylon the Coorg and Mysore system of planting under shade is one I often see referred to in your columns. A few remarks, therefore, from a practical planter, suggested by an experience of 29 years in Coorg and Mysore, may not be unacceptable to some who are contemplating a trial.

As to the planting of coffee estates in the open, and keeping of them after, I do not think South Indian planters have got up to the level reached by advanced Ceylon men, but while paying that well-deserved tribute to the perfect culture estates in Ceylon have had, in strict cleanliness and pruning, I have heard men say that South Indian planters do more to the soil, in the way of liberating it, by forking every year, in the dry season; and to the trees by more liberal applications of manurial composts. These are questions, however, beside what I intend to write you about, namely, "shade culture, and the kinds of trees preferred." I should like to say, if I can without running too far into your precious space, that thoughtful men here are beginning to believe that it is not the land that is so much exhausted, as the trees themselves that require renewal; and the replanting of old coffee estates, not with tea, but with coffee, has been successfully tried by several Mysore men. The ground, in that direction, was broken first, I believe, by Mr. Arthur Jupp, of Igoor, in North Mysore, who, as well as being a good planter, is a ready writer, and may be induced to record his experiences. Ten years ago, when I saw his work, he had some very promising young plantings on land that had been under coffee for over 30 years. He had taken out all the old giant coffee

trees, and planted up with Coorg plants, raised from seed I sent him. I had at the time in the same district myself a good large acreage (about 700 acres) under old Mysore coffee of the caste that no one now thinks of planting, namely, the chick tree, with straight upright branches, a very sparse bearer, but when it can be induced to give a crop, it produces what put Mysore coffee into the front rank in the London market: (Cannon's high-priced Mysore is from the old Mysore chick trees.) It is not, however, found to pay; as, when the trees are old, they bear only once in 3 or 4 years, so that the quality, in a commercial sense, does not make up for quantity. I hesitated in going to the length Mr. Jupp went, so I duplicated my places, by planting a seedling from Coorg seed between the old coffee trees in the lines of coffee, leaving the space between the lines for working. As the seedlings grew, the branches of the old coffee trees were sawn off until the stem was free of branches; a couple or more of suckers were then allowed to grow from the tops of the old trees, that thickened out, and afforded shade, and the sight of these high suckers, often bent down with crop, was a novel one. This hacking about renewed the vigour of the old veterans probably, and set the sap flowing in a new direction, I suppose, for they bore crops for a while; but there is not one of them left now: they have all been uprooted by my brothers, who have since worked the places, and instead of the unproductive old trees, there are 700 acres of as fine Coorg coffee as any planter would wish to see. I mention this, as many of your Ceylon men will be interested in learning what can be done by re-planting old and exhausted estates, with coffee instead of with tea, as appears to be the rule in Ceylon. Your shrewd observer and writer, Mr. W. A. Tyler, has, I believe, seen the old estates I have mentioned, and may tell us what he thinks: I hope he will, as his ideas are always original, and to the point. In leaving that branch of the subject I set myself to write you upon, I should say, that in all cases of reclamation in Mysore the most careful attention has been paid to the covering of the estates with shade trees, of the most approved kinds.

The system, as to shading, practised in Mysore and Coorg may be classed under two heads: 1st, planting under the original forest; and 2nd, planting in the open, on the Ceylon plan, and raising shade afterwards. You will not have space for any lengthy remarks under the first head, and I will dismiss it as a plan not suitable to your climate and rainfall. Should any planter require, however, information and will state his wants, I will reply. The most successful and most lasting properties in these parts (Mysore and Coorg) are at a ruling elevation of 3,000 feet with an average rainfall of 50 to 80 inches. It is found that estates with the lightest rainfall produce the highest priced coffee and this may be accounted for probably by the fact that the trees do not get a severe check in the monsoon, and go on growing and maturing their produce while those in more severe climates stagnate in the cold winds and rain. I myself have a conspicuous example of that theory, in an estate I have in Mysore, with a mild climate and an annual rainfall of about 40 inches. Climate there is moderated by perfect shade, almost all secondary or planted, and the coffee bean produced is bold and dark green, bringing top prices. Without the perfect shade it is under, it could not exist: coffee growing in the open in that dry climate being impossible. To describe the system practised in these parts as to shading, I cannot do better than mention the best and most thorough piece of work in my opinion that has been done in

Coorg for some years, in every way: it is to be found on the Greenfield estate in S.-E. Coorg. It was almost clean felled, and the timber, which was valuable, worked out. It consists of 2 lakhs of plants, 5 x 5, put down in honest 18 in. cube pits in July and August of 1888. It was planted with good seedlings, and the growth was so rapid, that they were most of them fit to top in one year, except in places where original shade trees of good caste were left: here the growth was checked. In every second line and at every second tree a shade seedling or seed was planted. Mr. J. D'Vaz, the managing proprietor, who is an advanced and thorough planter, told me he should thin the shade out later, when grown. The estate had been well kept, and was thoroughly dug after the planting: the shade in a little over a year was above the coffee. Jak is a favorite tree of Mr. D'Vaz's, from seed planted at stake, two seeds in case of failure, the extra plant taken out after a year, if both come on. Many planters object to jak as the fruit falls about, breaking coffee branches, and attracting cattle and pigs, but that objection can be got over by reaping the fruit before ripe, and burying it for manure in the coffee. Planting shade trees in the lines, or between the lines of coffee trees, is a matter of fancy.

Now a few words as to the trees most suitable for shade, and I have done. Planters are very fastidious in this respect: some men like trees that others condemn, but that may be accounted for by differences of climate and rainfall. A tree that may flourish at 3,000 ft. and 60 inches of rain may look miserable at 3,500 to 4,000 ft. and a rainfall of 120 to 150 inches. I have worked in all varieties of climate. For Ceylon estates generally I may say jak is unsuitable, as the trees will be killed by a heavy monsoon, but in the lower and drier districts now being tried in your island it will do. A tree, suitable for Ceylon is our shingle tree, a bastard cedar (*Acrocarpus fraxinifolia*), a buttress tree, that throws red young leaves. I fancy you must have it in Ceylon, but I will be glad to procure and send some seed to anyone applying to me, or of any other kinds of trees we have. That is a tree that stands wind, and cattle will not touch it. Another tree in favor with many men, with me among the number, is the silver oak (*Grevillea robusta*). It agrees with coffee, throws considerable deposit of fertilizing matter, is a good break wind and cattle will not destroy it. There is the wild red cedar, your toon (*Cedrela toona*); of this there are two kinds, both good, and proof against cattle; when young they are attacked by a chrysalis, but soon recover, and rarely die from it. The other is *C. microcarpa*. The *spondias* are good shade: one gives a fruit used by natives for pickle. In the *Leguminosæ* come the *albizzias*, all liked for shade, and can be raised from seed, 1st *odoratissima*, 2 *lebbek*, 3 *stipulata*, 4 *amara*. Of the *Myrtaceæ* several kinds are liked: *Eugenia jambolana*., *E. zeylanica*, *E. floccosa*, and several others. The first-named throw a black fruit with a stone, very astringent but edible. The ficus is a large family, but there are several of that extensive variety disliked in shade. I suppose there is no country in the East so richly supplied with trees of the ficus tribe as Mysore. On a visit to Burma some years ago, I saw but two kinds—the common fig (*Ficus glomerata*) and the Pipul (*F. religiosa*) and wondered they did not send to Mysore for cuttings or stakes of the different sorts, for their avenue trees, as the roads were lined with miserable specimens, such as the goldmohur tree and such like. All the fig family can be raised from cuttings, or stakes, and some from seed, notably the one most in favor among planters for shading, the common fig (*F. glomerata*). The best way to raise it is to mix the fruit with

fresh cowdung, make it into cakes and dry on the wall in the same way as the natives dry it for fuel; powder when dry and plant in nurseries. It is leafless in the monsoon, but covered with foliage in the dry months, and coffee *always* thrives under its cool shade, in any climate, or at any elevation. The next best is *F. infectoria*. Many indeed prefer it before all others. It has long, dark green, glossy leaves, admirably suited for coffee. [That trees with bright, glossy leaves are always good for shade, may be laid down as the rule, while those with dull rough leaves are not good.] *F. bengalensis*, the banyan, is liked, and does in good soil that will admit its roots; it throws much deposit from shedding all its leaves once a year. *F. tuberculata* is a good tree that coffee likes. *Ficus retusa* is a good shade. I will mention but one more as good, *F. mysorensis*, a fine tree suitable for coffee, and throws liberal deposit. To give our local names would not help Ceylon men, but the Tamil equivalents can be ascertained from any of several books on botany. A tree that used to be in favour for shade is now condemned:—*F. Tsiela*. It is a beautiful tree however for avenues. I will now dismiss the figs. A good shade tree is *Bischofia javanica*, a tree with red juice and bark, common in Coorg and Mysore. Mangoes (*Mangifera indica*) are not in general favour, though some planters think them good shade. The *gumkino* (*Pterocarpus marsupium*) a fair shade giving manurial deposit. I will mention only the *Melias*. The *M. indica* or the sacred margosa tree is good for shade in dry districts, and can be raised from seed. *M. composita* is the quickest-growing tree known, but opinions are divided as to its value for shade.

If I can give any practical information to any planters in need of it, on the question of Coffee Cultivation under Shade, I shall be glad to be asked through your medium. I make no profession to extensive botanical or scientific knowledge. I have, however, studied the history of trees, good or bad, for shading coffee; and the scant information herein given may be relied on an accurate, as tested by long experience, and close observation. To enter at greater length on an explanation of the reasons why different trees are good and bad, would require much space. There are many other trees than those I have mentioned, that are in favour, and which you have in Ceylon, and if the botanical name can be given, I can supply information to any planter wishing to try a clearing on the Mysore and Coorg plan of coffee under shade, and which is the only principle now practised here.

J. P. HUNT.

OYSTER CULTIVATION OF BENTOTA.

Bentota, Oct. 10th, 1889.

SIR,—Mr. Haly, the Director of the Colombo Museum, examined the oyster banks of the Bentota river with Mr. C. De Silva, with a view to increase and improve the supply to Colombo. These oysters are found only within three miles from the mouth and they can be greatly increased. If the Colombo folks wish to have good oysters, they should support Mr. Haly's scheme which he means to submit to the Governor. The present oyster dealers are not very careful in sending fresh and good oysters to Colombo.

C. S.

HORNETS IN TEA BUSHES.

Agrapatana, Oct. 15th.

DEAR SIR,—Quite a mistake to think wasps or "hornets" as they are called do not make their nests in tea. We have killed lots in the tea. Mark the bush with a long stick in the day, come in the evening with a lantern, a stick with some tow at the end soaked in kerosine oil and a box of

matches. When you find the nest put a lighted match to the tow and kerosine and the nest and its inmates are gone in no time.—Yours, W.

PLUMBAGO: THE DANGERS ATTENDING THE MINING INDUSTRIES OF CEYLON.

DEAR SIR,—In civilized countries, all mining operations are carried out under certain Laws and Regulations, as it was found that the masters and owners of mines were in the habit of considering their pockets much more than the lives of those who helped to enrich them. This was only done however before the crying injuries to which unfortunate men, women and children were suffering under was made public. In this country in the year of grace 1889, the health of thousands is being sacrificed in the mines of Ceylon, owing to the callous neglect of those in authority. There are a few pits in Ceylon where great depth (comparatively) has been reached, where the heat must be almost unbearable, with no arrangement for ventilation, and where blasting operations are carried out. Anyone who has been in an ordinary open cutting a few feet deep where blasting has had to be resorted to, must know how the smell of the powder hangs about the place for long after wards. What must it be in a mine where there is only one shaft? If those in authority (by which we mean every individual of the Legislative Council) could realize how many unfortunates are being daily slowly poisoned in the mines of Ceylon, they would surely make some endeavour to mitigate the evil. It must be pretty generally known how injurious carbonic anhydride (commonly known as carbonic acid) is even when mixed with a large proportion of pure air, but the injury it must be doing to the unfortunate Ceylon miners with only one shaft for ventilation can be easier imagined than described. Owing to the sp. grav. of this gas (it being so much heavier than air) it hangs about the mine, and the fact that those working have for a time left off work does not tend to purify the air. Moreover the carbonic anhydride from the lungs of the miners is supplemented by that formed from the combustion of the gunpowder to say nothing of the potassium sulphide and sulphate formed when gunpowder is used in blasting operations. This want of ventilation however is only one of the many evils that the Sinhalese miner has to suffer, and which could be easily remedied by legislation and the appointment of a Government Inspector of Mines. With two shafts, a large fire at the bottom of one would be quite sufficient to create a good draught, or what might be even more suitable for a Ceylon mine, a good circular fan driven by steam or hand power would clear the mine of all foul gases in a very short time, and where there are not many workmen, the fan need not be kept continually going. Another very good reason for the Government insisting on two shafts, or an adit and shaft, is the necessity for having more than one place of escape in the event of an accident, should an adit and shaft be decided on instead of upcast and down-cast shafts, some special means of ventilation should be resorted to when the pits are sunk lower than the adit. Another source of danger to the miner in Ceylon is the rough ladder made of bamboos or common wood, with steps far apart and tied with coir or jungle rope. Considering the lubric nature of plumbago, safe ladders should be insisted on. The timbering of mines should be well watched and care taken that the lives of miners are not risked to save the proprietors a few rupees.

As regards explosives, regulations should be laid down such as are in use at Home. For instances explosives may not be stored in a mine. They may not be taken into the mine except in case

containing not more than 4 lb., and a workman may not have more than one such case in any one place. Iron and steel pricklers, stemmers, and tamping rods, may not be used, and a shot that has missed may not be unrammed. Cartridges for blazing may not be made in a private house; they must be bought ready made, or manufactured in a workshop in connection with but detached from the store. The store must not be situated in a mine or quarry where persons are employed; or within a certain distance (the exact distance depending upon the quantity of explosive for which it is licensed; but 200 yards is the maximum, and should houses, &c., be subsequently built within the prescribed zone, the store must be removed) of houses, workshops, railways, roads, fires, etc. It must be substantially built of brick, stone, or concrete; or be excavated in solid rock, earth, or mine refuse not liable to ignition; and so made and closed as to prevent unauthorised persons from having access. There must be no exposed iron, steel, or grit in the building. Nothing may be kept in the store but the explosive and the necessary implements, which must be made of copper, wood, or brass. Lightning conductor required, unless the store be underground or licensed for less than 1,000 lb. of gunpowder, &c., &c., &c.

In this country surrounded as we are by careless natives ignorant of the danger they are incurring by having powder or other explosives and inflammable substances about them, or if not ignorant too lazy to take the necessary precautions, we cannot be too particular in our laws relating to them. At present I think if the Police Inspectors were to take the trouble to find out, they would discover that a great many natives have much more powder and kerosine oil in their shops than they have any right to by the existing laws. It should however be borne in mind by those in authority that it is not sufficient to pass laws but they should see that those laws are carried out, and any mining inspector that may be appointed should have authority to search where he has any suspicion of explosives being concealed.

As regards the strength of materials, a rule of thumb is that usually followed out in Ceylon, and till some responsible person is placed in authority, such is likely to continue.

It seems almost incredible that in a comparatively civilized country like Ceylon, that a few men with a little money should be allowed to subject a large number of their fellow creatures to sudden death or slow poisoning without the slightest attempt being made by Government to relieve the unfortunate sufferers.

We have very stringent laws enacted with reference to the health of our imported labourers, whilst the lives of the natives of Ceylon are being daily sacrificed for want of mining laws. We would not of course advise any very sudden measures being taken, or the plumbago industry would to a certainty be paralyzed.

Let a Mining Inspector with tact be employed, who must be in a position to insist on his orders being carried out, and use his power at first with leniency, and then it will be seen that plumbago mining can be carried out with as little loss of life as any other mining industries in other parts of the world.

In this letter I will not touch upon the very wasteful system adopted by the natives in working plumbago mines, as my present remarks are more especially directed at calling attention to the health and safety of the miners, but I hope the day is not far off when we shall find that the output of most plumbago mines are doubled and trebled and in many cases probably increased much more than this by the judicious use of machinery and ventilation.—Yours faithfully, GRAPHITE.

RICE CULTURE—PRACTICAL QUESTIONS.

DEAR SIR,—Will some of your readers who take an interest in the cultivation of rice inform me how much paddy is required to make a bushel of rice, and what is the ordinary cost of conversion to a villager in Ceylon?

Will they also state at what price either in a market, in the village where the grain was grown, or from peddling villagers they can buy home-grown paddy and home-grown and home-made rice?—Yours faithfully,
A HOUSEHOLDER.

[Pending answers which we should like to see from outstations, we may mention what is doubtless known to our correspondent, that popularly two bushels of paddy are required for one bushel of clean rice. But the following extract from a Report published by the Indian Government may have escaped the notice of "Householder" in our "Handbook":—

Careful experiments testing the relative proportions of husked and unhusked rice made by the authorities in India in 1876 have brought out one very important result, inasmuch as while the cubical contents (the bulk) of the clean rice is only one-half that of the unhusked paddy (according to the universally accepted formula—two bushels of paddy to one of rice), the weight of the outturn in rice is fully two-thirds that of the paddy. The natives almost invariably use dry measure for rice, and hence look upon the proportion of rice to paddy as one-half. It is really, with reference to the weight of the outturn, a proportion of very nearly two-thirds in paddy, on an average.—*Indian Government Report.*

—Ed.]

COFFEE PLANTING IN CEYLON UNDER SHADE AFTER THE MYSORE FASHION.

Oct. 19th.

DEAR SIR,—When it is borne in mind how strongly I have advocated the advisability of giving the planting of coffee under shade a fair trial in Ceylon, and thus lessen the risk of monoculture, which is apt to be too freely indulged in Ceylon:—when all I have written on the subject is remembered, you will understand my pleasure and gratification that a planter on the borders of Coorg and Mysore should have come forward to give the island the benefit of all his knowledge and experience in that region. Mr. Hunt does not touch on the past, and the blank dismay and despair that came over the planter in the dark days of the borer and the decline of the old Mysore variety of coffee. Mr. Hunt and his brother, Mr. Edwin Hunt, the Messrs. Anderson of Bargaai, Mr. Japp, the late Mr. Sanderson, Mr. Mockett, are among the chief of those who passed from the days of doubt and uncertainty, and laboriously and patiently began a new cultivation, studying shade anew, and gradually changing the variety of coffee. It is proverbially a bad thing "to swap horses in the middle of a stream"; and it was extremely plucky of those men to supplant their old trees, which were gradually falling them, with the sappy young Coorgs, when they were uncertain, first, whether the new bean would spoil their market, hitherto unrivalled, and second, whether the old style of shade would suit the new kind of coffee. But these men lived to reap the fruit of their labours, and anything more beautiful to the eye of a planter could not be seen than those old estates that had renewed their youth.

Mr. Hamlin said in my hearing that he had often heard that Coorg soil was very poor, but since he had seen for himself he was astonished to find so much good soil in Ceylon. Mr. Hamlin comes from farther south, from Wynaad and the Nilgherries, where the famous Oucherlonny Valley lies, and

where the soil is said to be very rich. But we are at present comparing Coorg and Mysore with Ceylon. In Wynaad and the Nilgherries coffee, I believe, is grown very much in the open in the Ceylon style, and they there get both monsoons, so they can also grow tea and cinchona successfully. But in Coorg and Mysore, when you keep away from the evergreen ghaut forests, and descend gradually into pockets of true soil under deciduous trees, the rainfall grows very scant in proportion to the ghauts or as compared with Ceylon. There you have a wonderfully deep and generous soil; but if you attempted planting in the open:—have I not quoted the history of the borer in my review of Mr. Elliot's book which appeared in the *Tropical Agriculturist*? You must, as Mr. Hunt says, "pay the most careful attention to covering of estates with shade trees." So far this is the Indian side of the question. Now comes the Ceylon side. I need not repeat what I have often urged, that the washed steep ghaut estates in Ceylon are unsuitable for shade experiments in connection with coffee, especially on the Kandy side. Supposing you attempted shade in Kelebobka, can any reasonable man hope for flourishing coffee fields where they need all the sun they can get? This applies to the higher districts on the Kandy side where the soil is good; and where the soil is inferior the objection is stronger. For shade cultivation you must get away to Uva, except Dumbara, with its great similarity to Mysore as regards soil and rainfall, though the climate is very much hotter. Here Mr. Hamlin has been at work and will soon have data to go upon. In Uva many places lying low in Badulla and Haputale will give you the dryness of atmosphere and deep soil to make shade experiments possible. In higher elevations, and where the land has been much washed, the resources, of the soil are strained in the effort to make shade grow, and afterwards again strained to save the coffee from being injured by the shade. Thus you have not the necessary stimulating power required for the combined culture.

In Ceylon the generally humid atmosphere enables plants to exist at first on a forced and false vitality and subsequently to become the prey of blights which are the result of an unnatural state in the organization of the plant. Leaf disease was proved to be greatly strengthened by wet weather, as Marshall Ward pointed out; thus in Mysore and Coorg the condition of dryness had to be considered, while in Ceylon the conditions of extra moisture have to be looked to.

All this reduces the area in Ceylon available for coffee planted under shade; but there is quite enough land suitable to make this new cultivation a considerable one if men once believed in it. Mr. Hunt does not mention the green-bug. Unlike black-bug, I believe the green-bug likes a dry climate; and this becomes an extremely important factor when the responsibility of giving advice, which possibly may be followed, is considered. I myself believe that as *helopeltis* succumbed to the sweet influence of shade in cultivation; as the borer ceased his fell ravages when the planter promoted osmotic action by growing shade over his coffee; and as *Hemileia vastatrix* was extremely modified by the benefits of shade;—so will the green-bug cease from troubling.

But now comes a very important consideration: Contract weeding, in this cultivation, must be given up, weeds kept down by digging, disturbing the soil, burying what Mr. Hunt calls "the liberal deposit of fertilizing matter" from the shade trees, and liberal manuring with bulk and artificial.

Mysore is exceptionally favoured by the cheapness of labour, and abundance of local manure procurable, both in bulk and in the various oily poonacs. I used to buy cattle dung at a very cheap rate from the villages; and that, with estate cattle-sheds, tank-cleanings, farm yard compost, pulp, and scrapings of grass plots, formed a fine mass for the mule-carts to run out, months before, to depôts near the fields to be manured. Then oily rich poonacs of various sorts used to be brought to the door, and bones, too, galore, for is it not a country of drought where cattle die and vultures soar? It was found, however, that it paid to get bones and poonac, in any desired proportion prepared by Mr. Hart of Binny's Mills, Bangalore, where the oil of the poonac lubricated the teeth of the bone-crusher, and the mass was thus thoroughly mixed.

Three proofs, that Ceylon soil cannot be named alongside that of Mysore, are

1st. That in Mysore land can be planted several times over and produce good plants.

2nd. That in Mysore weeds can be allowed to cover the coffee at the end of the monsoon and yet do no visible damage.

3rd. That in Mysore, where cultivation is thoroughly carried out, you can drive your stick well into the soil, and the subsoil is never touched.

On most estates in Ceylon the whole place is subsoil hard, and washed and baked and scraped. How can you think of ever attempting Mysore cultivation there?

To sum up, humidity, hard subsoil, dearness of labour, cost of manurial supplies, contractor weeding, are all against the cultivation of coffee under shade. Take the three places, Dumbara, Koslanda, and Badulla; and learn gradually and painfully the necessary experience, supported by the necessary faith and capital; and if this succeeds the cultivation can be extended. I cannot go into the question of suitable trees save recommending *Ficus glomerata*, jak, and *grevillea*.

It would be well worth the while to enlist Mr. Hunt's assistance in the procuring of varieties of shade recommended by him and also the ordering of coffee seed from him by those who intend to give the cultivation a fair trial. The price of coffee surely is an inducement; and what pays better than coffee when it bears?! One day's picking of fruit on a coffee estate will nearly equal a month's worry on a tea estate. Who knows this better than the Ceylon planters? Mr. Hunt's advertisement of seed is opportune, as I have had numerous applications as to where to get Coorg seed,—one coming all the way from Perak.

W. A. TYTLER.

TEA IN THE NORTHERN DISTRICTS OF CEYLON.—A tea proprietor north of Kandy thus expresses his dissatisfaction with recent experience of weather:—"We have had a rough time of it this year, and tea estimates are terribly behind. I would be ashamed to mention the magnificent break-down in our places. The estimate properly burst up. I take comfort, however, that this enforced rest which the tea has enjoyed—and which I have not—will have a good effect in the future, in the shape of overflowing harvest. Meanwhile with these fine prices, and the small returns, you have the pride taken out of you and a humble spirit takes its place. The wet and cold wind is what has done it. Commend me to the life of an agriculturist, if you want to realize to the full your dependence on Providence."

SALT IN COCONUT CULTIVATION.

One of the objects I had in view when penning my contributions on this subject has been attained. It has attracted the attention of the Press. Would that the attention of the Association which avowedly represents Native Agriculture and of the Government will finally be arrested!

I will now, with your permission, notice the article in the *Observer* on salt as manure. It is asked of the coconut palm, "Why does it specially love littoral formations and flourish in the ocean breezes? Is it solely for the sake of a soil and atmosphere largely impregnated with salt?" Not solely, for salt is not the one and only food of the palm, although it is a very important part of its food. From observation I should say it loves a free soil with water within easy reach of the roots, as much as a soil impregnated with salt. Can anything be better than the trees one sees in the Cinnamon Gardens of Colombo, both as regards growth and fruitfulness, growing on as free and hungry a soil as is to be met with anywhere? This soil, though not impregnated with salt, must have a considerable quantity of it in its composition, being within the influence of salt laden breezes. The further we go inland, the less are we within the influence of salt breezes, and the farther we are from the natural conditions under which coconuts grow. I therefore think we ought to comply as much as lies in our power with those natural conditions by increasing the porosity of our soils and by applying salt to them.

I am aware that there is a difference between sea water and salt crystals, and became first acquainted with it in the seventies, when the minds of everyones interested in coffee were exercised to devise remediee to circumvent leaf disease. Mr. Northmore, then a Merchant in Colombo, thought he discovered a remedy for it in sea water, because a Liberian coffee tree growing in a compound at Kollupitiya was free from leaf disease. In a letter he wrote to the *Observer*, he gave an analysis of sea water, showing that it has many constituents dissipated by evaporation into salt. He therefore went to the expense of sending up to Whyddon in Pussellawa, a property he then owned, sea water instead of salt for the purpose of experiment. All this simply to shew that I was not ignorant of the difference between sea water and salt.

I am aware that salt in large quantities is fatal to vegetation. I do not advocate its use in unlimited quantities to our soils, for there is a grand difference between our soils and those on the sea shore. Our soils are clayey and retentive, owing to their constituent particles being closely—too closely—packed, while the sea-shore sands are so free that moisture must pass through them as through a sieve. All the salt water they contain must be represented by the thin film that coats the outside of each particle of sand. That coconut plants have a very hard struggle for existence on the sea-shore against salt-laden winds does not affect the argument one way or the other. I said that it was difficult to imagine a soil in our Island, exposed as it is to violent monsoon storms, quite devoid of salt, so that I admit that salt reaches us on the "wings of the wind," but my belief is that we do not receive it in sufficient quantity to satisfy the wants of our coconut trees. It is kind of the *Observer* to credit me with being sane and sensible generally. I do not believe that I am quite bereft of these valuable attributes. But when I am accused of writing "wildly" by attributing to me what I did not say, the accusation recoils on the head of the accuser. I nowhere in my communication under notice advocated the use of salt in "almost unlimited quantities," for I know that coconut palms cannot live by salt alone. It is unfair to credit me with the bald statement that "salt can never be present in too large quantities in a soil on which coconuts thrive." Take the whole sentence please and refute it if you can, Mr. *Observer*. "Observation shows us that salt &c., &c." And what follows? "On the sea-shore the trees seem none the worse for the salt-laden waves that break at their

very roots." I said and meant nothing more than these words imply, and I emphatically protest against a meaning contrary to my intention being placed on my words. I did not use Liebig's dictum with approval, for all I contended and contend for is the issue of salt for agricultural purposes at special rates. If salt be issued at special rates to the manufacturer—the fish curer—it ought *a fortiori* to be issued on the same terms to the producer, the agriculturist.

True enough, experiments have not established the value of salt in coconut cultivation, and why? Because the cost of such experiments will be prohibitive with salt at the usual rates. My contention is that no risk to the revenue will be incurred by issuing salt at special rates for agricultural purposes, under proper safeguards and mixed with some objectionable substance like night soil. Experiments may have proved the possibility of thoroughly purifying such salt, but the probabilities that such experiments will be carried on to fit it for culinary purposes are in the highest degree remote.

I have not asserted in general terms that salt is of special value manurally. All I say is that it has a special value in coconut cultivation carried on in regions beyond the influence of salt-laden breezes, or to be more accurate, that have not the requisite quantity of salt in the soil. I base this my belief on the results of my observation of the difference in the habits of the coconut trees growing on the sea border and in inland districts, especially as regards the latter not being able to support their fruit branches without extraneous air, on the results of the analyses of every part of the coconut tree, and an axiom in agricultural chemistry that plants cannot thrive or attain perfection in a soil having one of its constituents present in insufficient quantities. All the literature available on salt as a manure refers to it in the cultivation of cereals and roots, and for these salt in minute quantities is sufficient. To say that because salt does not invariably yield adequate results in European agriculture, therefore it cannot be of manurial value in the cultivation of a product whose natural home is on the sea-shore, is to assert what cannot be assented to by those who have given the subject of agriculture due consideration, as being opposed to reason. Salt has an indirect value besides. It has been termed a digester, because it acts in the soil as a solvent and liberates ammonia, potash and phosphoric acid, the three principal constituents of all plant food. Another property of salt to which I draw attention is its ability to draw to it the water of the atmosphere. This property of salt renders it of very high value in regions where a lack of moisture reacts very prejudicially on the crop. Happening to turn over the leaves of the 2nd volume of the *Tropical Agriculturist*, I accidentally came across a contribution on "Manures as absorbents of water" by Stephen Wilson, who is I believe Consulting Chemist of the Highland Agricultural Society. The lessons he draws from a series of carefully conducted experiments have a special bearing on the subject I am now discussing. He says:—"If in a dry season a given manure has the property of absorbing moisture from the atmosphere more copiously than the soil with which it is mixed, the roots of plants growing in that soil and manure will be better supplied with water than if that manure were absent." All will assent to that proposition I am sure. He experimented with various manures and found that while ground coprolite absorbed 3 per cent of water, the potato manure absorbed 92 per cent. The hygroscopic properties of other manures were intermediate between those two extremes. To find out the composition of the potato manure I consulted Ville and find it composed of Acid Phosphate of lime, Nitrate of Potash (salt-petre) and Sulphate of lime (gypsum): substances all more or less having an affinity for moisture.

It is interesting in this connection to explain how the roots get water. Mr. Wilson says where the roots are in direct contact with water, in its liquid form, the matter is plain, but not so when water is not found in a liquid state. For the purpose of determining this he grew certain seeds in glass vessels filled with stones and free open soils, putting them

near the edge of the vessels. Whenever roots made their appearance near the sides, he examined the root-hairs with a glass and found them covered with small particles of moisture. His conclusion on this discovery was that in dry soils roots do not go in search of moisture, but water seeks them and settles on them in a condensed state. "Now a manure that has a highly hygroscopic capacity will keep the soil around the roots of plants well charged with moisture; evaporation will fill the interspaces of the soil with vapour, and will thus enable the moisture withdrawn from the air to be condensed on the roots. If any part of plant food—ammonia for example—may be vapourised and condensed within the vesicles on the roots a different view is opened up." "Two main causes combine to render hygroscopic manures rapid in their action, they are soluble and they have the capacity of absorbing the moisture which renders them fluid." "The more powerfully a manure abstracts moisture from the air, the more powerfully will it resist the giving it up again. During the night moisture will be drawn from the air, or during the day a part of this moisture vapourised within the soil will be condensed upon the root-hairs in the form of minute dew drops to water the plant." Can anyone doubt after this testimony borne to the value of hygroscopic manures by a scientist after a course of prolonged experiments, that salt, apart from its manurial value, has a value all its own as an applicative to lands suffering from annual drought?

It has just struck me that I have experienced of the use of salt as a manure for coconuts. On pleading for salt as a necessary adjunct of coconut cultivation, and for application to a backward field of young coconuts some years ago, a quantity of ham salt was placed at my disposal. I applied a coconut shell-full of it to each plant after disturbing the soil round it slightly. Seeing the plants every day I was not able to notice any change in them, but a gentleman who saw them after an interval remarked that they had grown much since. Mr. Davidson of Jaffna—who was perhaps the most able man engaged in the cultivation of coconuts, judging by his controversial letters on the cultivation of coconuts addressed to the *Observer* and embodied in "All about the Coconut Palm," and which shew up a high authority on coconuts at the present day by whom the *Observer* always swears; and who was further the Gamaliel at whose feet Mr. Jardine, a high authority at the present day, sat—uttered no uncertain sound on the value of salt in coconut cultivation. He writes:—"Were I to say it (salt) acts as a stimulant, I might state what I could not explain; but I could point to its operation in the animal economy, as proof of its possessing properties, adapting it peculiarly to a tree in which ever circulating sap is perpetually varying in constitution and density. We can thus understand why the coconut tree thrives best where it feels the influence of spray." He says the quantity of salt a tree requires, as determined by analysis, does not exhibit fairly its relative value as a manure, because analysis can take no cognisance of the properties belonging to salt. This is instanced as a case where practice triumphs over theory. "Salt is the manure he must have." Dr. Gardner is quoted as saying that in the Brazils a man would walk a great distance, pay high for a load of salt and apply it to one single tree! For the sake of its salt, the Jaffna planters used to send their carts to the beach to gather and bring sea weed. If as high a value was placed on salt as a manure for coconut trees in regions within the influence of the sea spray, surely we have displayed lamentable ignorance in ignoring its value in inland districts.

I see the *Observer* challenges the statements that salt is used in paddy cultivation, and that it is destroyed by Government at a high cost. You are responsible for the former statement. To my knowledge, salt is considered inimical to paddy cultivation, but this prejudice is senseless and is based on paddy being killed outright on land which during floods is submerged by salt-laden tidal waves from the sea. Why, such submersion will be enough to kill even a coconut tree. Salt cannot be entirely washed out of such

lands subsequently, and where can paddy yielding better results and with a handsomer appearance be met with in the Western Province than in the Pasdum and Raigam Korle fields and those at Mutturajawella, specially liable to such submersions? The name Mutturajawella is self explanatory. Salt is discarded, however, in paddy cultivation. I am responsible for the statement that excess salt is destroyed. Unfortunately, writing from here I have no excess to Administration Reports to support that statement; but I have a clear recollection of your denouncing such destruction in your annual criticisms of Administration Reports. By the merest accident I happen to be in possession of the Administration Report of the Northern Province for 1884. In it I find the very large sum of R1,333-08 expended for the destruction of salt unfit for collection. What is the meaning of this term? I take it that it refers to the residual salt in which the impurities have settled down. That this salt is fit for human consumption and will be so used abundantly proved I think by the fact that so large a sum is expended in its destruction, and that it is salt in excess of requirements by its not being collected. In this connection it may be noted that the production of salt, including watching, weighing, removing to store and storing ranged between 12-50 and 19-73 cents per cwt., so that its sale at 40 cents per cwt. to agriculturists, if manufactured beyond present requirements, ought to aid the revenue sensibly. This communication has unconsciously attained an inordinate length. I must therefore discuss the coconut leaf disease in another letter.

I cannot conclude this without offering a welcome to Mr. Christopher Drieberg, the newly-appointed Superintendent of the Agricultural School. He was the first Burgher youth—more shame to them!—to leave the beaten tracks of the learned professions and take to Agriculture as a study. He deserved encouragement for this at the hands of the Government, and he has fairly earned it by his distinguished career at Edinburgh. May his attempts at instilling the information he gained at such expense be as successful as his own performances. I hope he will take part in the discussions on agricultural subjects occasionally raised in the local press by persons whose knowledge is but empirical—like myself. We are groping in the dark, vainly struggling for that light, much of which he happily ought to possess.—B.—Local "Examiner."

HILLCOUNTRY PLANTING REPORTS.

FINE WEATHER AND ITS EFFECT ON TEA—A SCENE OF QUIET BEAUTY IN NUWARA ELIYA—FURZE VS. BROOM—BUILDING IMPROVEMENTS IN THE SANATORIUM—THE LORANTHUS PARASITE ON AUSTRALIAN TREES.

NANUOYA, Oct. 22nd.

Yesterday continued bright throughout, the heat being tempered by a gentle movement of the air in this valley and by pretty strong breeze in Nuwara Eliya. This morning the sun shines into the valleys of Dimbula, while the ranges around are crowned with haze,—haze of the description which indicates heat rather than rain. If the fine weather continues, tea planters will be able to take changes from their constantly pressing duties during the Tivali holidays, which commence tomorrow and which will close only with the end of the week. If some portion of flush goes "bangy" (hard) so much the better, probably, in many cases, for the strength and future yield of the bushes.

Yesterday, as for several days previously, the weather in the Sanatorium was about as perfect as it could be, but for the heat of the sun, which, however, has been largely tempered by cool winds, which yesterday were strong enough to cover the Lake with broken wavelets. A boat rowed over the surface of the water, with groups of cattle browsing on the shores, gave animation to a scene, the general characteristic of which is quiet beauty. While admiring the glowing gold of the masses of furze blossoms, I could not help regretting that

in the fight for "the survival of the fittest" its general companion in the old country had here had the worst of it, so that in writing of the tortuous stream which meanders across the Plain, we cannot write of

"The burn stealing under the lang yellow broom."

In the early days of Baker's Farm, I can remember a fence in which broom was as prominent as fuchsias. The latter have lingered on, but the broom has disappeared to such an extent that, it was with a start of pleased surprise I saw a solitary specimen with a few of the beautiful blossoms characteristic of this elegant plant in the privet-like fence of one of Cotton's Cottages. Talking of cottages, Mr. Cross has made a very pretty addition to their number, while the fine front of Mr. McLaren's new Store has relieved the ordinary architecture of the bazaars.

In going about I kept my eyes open with reference to the prevalence of the *Loranthus* parasite on the now largely prevalent *Acacia melanoxylon*, so pine-like in its general appearance and mode of growth, often beautifully and sharply pyramidal. The parasite seems very capricious in its attacks, often infesting half the trees in a grove, or one out of a pair of trees, while the rest are perfectly free. The older trees, of course, suffer the most, and in the case of some of these the foliage of the parasite is more prominent than that of the original tree. If picturesque effect is desired, then the *Loranthus* may be allowed to work its will in sucking the juices from the bark of the trees. But if the longevity of the trees is an object, or if they should be grown for firewood and timber, then war should be waged against the parasite. A coolly sent round occasionally with a large knife or sickle attached to a long pole could easily keep the trees clear of their insidious enemy. So serious did the Madras Government deem the attacks of *Loranthus* on Australian trees which are grown largely on the Nilgiris, at Ootacamund, Coonoor and Wellington, that Dr. Bidie was deputed specially to report on the evil and its remedy. I have some recollection that the eucalypts were also attacked on the Nilgiris, but in Nuwara Eliya this is not the case; and if I am not wrong in my recollection, it is possible that the terebinthine principle in these trees is adverse to the parasite. It attacks old rhododendron trees badly some times, and yesterday I saw a specimen on a peach tree. The fine specimens of *A. melanoxylon* near the Kacheheri are perfectly clean, and the other Australian acacias seem never to be attacked. I reserve further notice of Australian and other plants at Nuwara Eliya, as it is past time.

KINO-RED—BLUE-GUMS FOR TIMBER—OTHER EUCALYPTS, WATTLETS, &C. IN THE NUWARA ELIYA LOCAL BOARD NURSERIES.

NANUOYA, Oct. 23rd.

Before noticing a visit I paid to the Local Board Nurseries at Nuwara Eliya (which are to be taken over by the Forest Department) under the guidance of young Mr. Tringham, I feel bound to compliment one of your composite demons and the proof-reader on their ingenuity in so perverting my statement that the presence of "kino-red" (I am pretty sure I used the hyphen) contributed to the strength of the timber of a eucalypt, that I was made to say that such strength was due to the presence of "kindred." A proof reader of ordinary intelligence might have seen that this was absolute nonsense, and referred to the MS. Seeing, however, that misdate yesterday's letter 23rd, I content myself with a mild expletive, emphatic but not profane, thus failing to imitate a late jocative civilian, who, receiving a proof with many printers' errors, wrote

on the margin, "This is the work of the devil." It is a fact, however, that some of the best Australian timber is coloured red by the presence of *kino-red*. Such is not the case with the blue-gum, the timber of which tree is pure white. It is difficult to season, being apt to warp and get scored with external cracks. It is very useful for fences, poles and supports of verandahs and buildings. Even in our exposed region I have no doubt it could be grown profitably in groves, planted 6 by 6 feet as the foresters are about to do, or even closer, if the main object was to obtain firewood. For this purpose the trees (all save select specimens of good growth reserved for timber) might be cut down at 5 years of age. It coppices so freely, that we have failed in many cases to destroy the vitality of stumps of trees felled, because of the injury inflicted on our tea. An appreciable acreage thus treated could not but yield good results even on our exposed slopes and ridges, the quantity and quality of the timber, of course, increasing with more favourable conditions of climate and shelter, such as exist on the eastern side of the dividing range. For rapidity of perpendicular growth the blue-gum surpasses most trees; for rapidity of umbrageous growth *E. pauciflora* is quite its equal, but then the latter requires so much lateral space that nothing like so many of these trees can be planted to the acre as of the former. The possibility of the blue-gum being profitably grown to produce timber for tea boxes adds further interest to this specially fast-growing tree, which is also propagated from seed more readily than many of its congeners. The presence of many thousands of seedlings of *E. globulus* with their bluish-green foliage, at once attracted attention in the Nuwara Eliya nurseries, and their very abundance may probably have decided the officers of the Forest Department to utilize them in re-forestation of the slopes of the range to the south of Longden Road. Red-gum plants were also present, but not in such large numbers, while of the pretty and sweet-lemon-scented *E. citriodora*, there was an appreciable group. Of this handsome, slender tree, valuable for its timber as well as for the fine essential oil yielded by its leaves, a few might well be grown in the neighbourhood of bungalows. Baron von Mueller says of *E. citriodora* that it is "particularly adapted for a tropical jungle climate." The leaves yield one per cent of fragrant oil, resembling that of lemongrass. "Fresh foliage splendid for strewing about rooms, or placing in large vases for fragrance and sanitary purposes also." There ought to be a demand for the well-grown plants at Nuwara Eliya, but the utmost care will be necessary in their removal. Many of the eucalypts are so impatient of the process of transplanting that cultivators are advised to plant several seeds *in situ*, rather than grow plants in nurseries. This valuable species is, unfortunately, so delicate, that in order to be certain of three plants succeeding no fewer than twenty ought to be ordered!

But I visited the Local Board nurseries specially to see the young plants of that valuable and beautiful wattle, *Acacia pycnantha*, recently introduced. A protean plant truly! The cotyledons and the first pair of leaves, succeeding these, are large, round, and succulent. Then come whole and divided leaves, the final foliage so closely resembling that of *A. decurrens*, that it would be difficult to distinguish between the two plants, only that the stems of the young plants of *A. pycnantha* we were shown were of a reddish bronze hue. Plants of *Cryptomeria japonica* were present in considerable numbers, but what chiefly excited my interest were seedlings,—little tufts of needle-like leaves,—which

my guide assured me had been raised, with others planted out, from seeds of the Norfolk Island pine, *Araucaria excelsa*. This is "a magnificent tree of unsurpassed symmetry, sometimes to 220 feet high, with a stem attaining 10 feet in diameter and with regular tiers of absolutely horizontal branches, one for each year. The timber is useful for shipbuilding and many other purposes. Growth in height at Port Phillip about 40 feet in 20 years. With *A. Cunninghamii* amenable to almost any soil, except a saline one, and not subject to any disease." So writes Baron von Mueller, who is generally so careful that I am surprised to see him commit himself to the statement that this noble tree puts out exactly one tier of horizontal branches per annum. It is obvious that growth is dependent on climate and season. Here we have some beautiful specimens, one of which has grown 36 feet in nine years, or at exactly twice the rate per annum which the tree attained in the vicinity of Melbourne. Our tree has not only grown four feet per annum, but has put on, in the nine years, no fewer than 22 tiers of horizontal branches. The top of this beautiful tree, looked at from underneath, resembles a star, while viewed sideways the likeness to a cross is most striking. In 1880 a wardian case of this and other Australian plants was kindly presented to us by Dr. George Bennett and Mr. Charles Moore of Sydney, the latter the discoverer and describer of *A. cookei*, which vies with *A. excelsa* in magnificence and beauty. We were led to understand that it would be of no use indenting for seeds of the Norfolk Island pine, as they would not preserve their vitality. We were, therefore greatly surprised at the success in Nuwara Eliya, and we looked with some suspicion at the young plants, those planted out and bearing a first tier of branchlets showing only masses of big needles. But after the changes in the foliage of gums and wattles, we need not feel surprise at anything. Mr. Tringham assured us the seed was ordered and came (*carefully packed in a tin case*) as that of *Araucaria excelsa*, and now we trust this most magnificent of the pines will become not merely an ornamental tree attached to hill bungalows, but one of the chief trees used in the re-forestation of our mountain region. Four feet per annum, or 36 in nine years, at 5,800 feet altitude is surely encouraging. *Araucaria cookei* has grown equally well here, but *A. bidwillii* is of slower growth. *A. cunninghamii* we do not seem to have. That we ought to get and the kauri pine of New Zealand, *Dammara australis*, equally famous for its gigantic size, excellent timber and valuable varnish resin, worth £50 per ton, and of which pieces weighing a ton have been found.

PLANTING IN DELI.

(From the *Strait Times*, Oct. 15th.)

In Serdang a whirlwind has wrought widespread havoc. On one estate about sixty thousand tobacco plants were destroyed. The blast moved S.W., and all along its track the jungle was laid low, the trees falling before it like reeds.

Several planters at Marudu Bay, in British North Borneo, have written a letter to the *Delhi Courant* to set the former country right with the outside public. In refutation of rumours to the contrary, they point out that in healthiness Marudu Bay compares favourably with Deli, and that the coolies have adequate medical attendance. The Government lend the planters now more effective assistance against coolie desertion, which has, in consequence, almost ceased. On the other hand, the opening up of new estates encounters difficulties from scarcity of labour, sickness, desertion, and other disappointments which render the

first crop smaller than might be expected under ordinary circumstances. It is no wonder that two companies, finding these obstacles insurmountable, gave it up. They have, however, learned experience sure to be valuable in subsequent efforts. The planters in question point out that Marudu Bay does answer requirements judging from the results gained on the Ranow Estate, the only one which has been carried on long enough upon a large scale. The tobacco grown there has been favourably received in the European market.

PLANTING IN WYNAAD.

THE WEATHER—COFFEE—AND CINCHONA.

I do not usually begin with the weather, but we are just now enduring such an extraordinary variety of it, that it has become an all-absorbing topic of thought and conversation. Imagine the worst burst of all the monsoon in the middle of October! After more than a hundred days' consecutive rain, we rejoiced in a fortnight's sunshine. But this has been followed by a tremendous burst of from three to five inches a day, and towards the head of the Ghauts this amount must be doubled. The rain is accompanied by fierce gusts of wind, and altogether it is far more like July than October. Needless to say, the effect of so much wet is very disastrous, crops falling off terribly, and leaf rust and leaf rot are rampant. No work can be done. The coolies do not even go through the pretence of coming out for roll-call. The weeds are growing as only such vile things do. The crop is naturally very backward, it being impossible for the berries to ripen in their constantly sodden condition. Most of us pleasantly anticipated a fairly decent crop, but, with the fates thus against us, we really cannot venture to make an estimate. This seems doubly hard with the coffee market in such a splendidly promising condition. In spite of these troubles, however, planters are tolerably cheerful as regards coffee, though those engaged in barking cinchona are hardly happy, for it is quite impossible to dry it in the present state of the atmosphere; and talking of cinchona, a more hopeful prospect in the market is the latest good news that we have received, this pleasure being considerably mitigated by the fact that a large amount of the succirubra in the district is dying out, and has to be immediately coppiced "to save its life." There is no apparent cause for this. With great suddenness whole fields die out. But it is generally supposed that the roots have reached soil not suited to the plant, and that this has produced such desolating results. The ledgeriana does not seem to be so effected, but most splendid fields of succi. are transformed into bare poles. I believe that in the Oherambaddy district, the cinchona has so far shown no signs of this mysterious and most unwelcome disease. We are becoming unpleasantly aware of the fact that preparations are being made for coffee robbery on an extensive scale this year. There is absolutely no coffee to be had in the country at present, and large contracts for it are being arranged for with every possessor of half a dozen trees. Such contracts can, of course, only be fulfilled at the expense of the large estates, and unfortunately our Police force is quite inefficient in numbers; Col. Christie was up last week inquiring into the matter, but it is evident that unless considerably more than the usual amount of energy and vigilance is exerted in the Police department, we must be very heavy losers during the coming crop season. The "Settlement" has caused great woe and desolation amongst small native land holders. In fact, we hear that it has ruined so many of them that a great number of their old employés, the Puniyahs, will be without work, and ready for any amount of coffee-stealing mischief to occupy their idle hands.—*Cor., Madras Times, Oct. 21st.*

A FALL AGAIN IN CINCHONA BARK: THE NEED OF A SYNDICATE.

(Communicated.)

The fall in cinchona to 1½d again is a surprise to most people just when a rise was expected.

Can anyone have telegraphed home what appeared in the local "Times," that the endeavour to form a Syndicate had been abandoned, I wonder? It looks much like it, for I hear that a message has come to one firm asking "What about the Syndicate?" On inquiry I hear that the promoters are awaiting replies from Java and India, and the Syndicate will deal now at any time with all who will send their cinchona to it. The necessity for the Syndicate is pretty well established by the fall in the market telegraphed today, brought about by some sinister influences.

PROSPECT FOR OUR GEMMING ENTERPRISE.

According to the letter of our London Correspondent received by the present mail, there appears to be every prospect now that our advocacy of steps being taken by British capitalists to develop the wealth in gems of our island, may receive practical and early fruition. Although full details, and any mention of names in association with this promised result, are still withheld, we can gather enough from what has been written to satisfy us that the arguments which we and others have advanced have had the effect intended of directing the attention of home capitalists to the subject and of assuring them that there exists a profitable field for investment in this long-practised but little developed local industry. We confess ourselves to be rather surprised at the scale on which it is intended, apparently, to commence operations. A capital of half-a-million sterling—that being the amount mentioned to our Correspondent as contemplated—is rather a large order for which to seek public credit; but there is the precedent set in the Burma Rubies Company, and doubtless those who are promoting the matter at home are the best able to judge of what may be the wisest course to pursue. Certainly the announcement of such a capital must be likely to invest the undertaking with an appearance of imperial importance, and if the names likely to be associated in making the demand for its subscription should prove to be of the weight and influence it has been stated to our Correspondent they are possessed of, the invitation to subscribe may meet with as ready a response as was given to that which resulted so successfully in the case of the Burma Company taken up by Messrs. Rothschild.

Of course we must discount the anticipations held out, by the qualifying fact that the influential support promised is held dependent upon the character of the Report to be made by an expert of high qualifications, whom, we are told, we may expect ere long to see arrive among us commissioned to undertake a thorough preliminary examination of the whole subject. We should have had little faith in what we have previously written with respect to our gemming fields if we entertained serious doubt that the result to that examination will be a Report of a character likely to be attractive to investors, though we can hardly conjecture beforehand what steps will be taken by the expert mentioned in order to satisfy himself of the practicability and probable result of the search for gems on the evidently enormous scale contemplated. To be efficient, there is no doubt that the preliminary operations will have to be of a costly character; but we are told that the necessary funds—and these to a very large amount—have been guaranteed by a Syndicate already formed, and that their negotiations with an expert of celebrity to come out here and direct the expenditure, were expected to be favourably concluded in about one

or two weeks at furthest from the date of the communications made to our Correspondent. There therefore appears to be good reason to expect that before the end of the year we may see investigations, intelligently and scientifically directed, and backed up by fully adequate monetary resources commence within our gemming districts.

That the promoters of this new enterprise have the courage of their convictions, is evidenced by the large speculative outlay they have thus consented to sanction, while the fact stated that lands proved to be gem-yielding in a high degree have already been secured by agents of the Syndicate, proves that no time has been lost in placing the preliminaries of the proposed Company on a sound material basis. When the scheme was first broached at home, it would appear that it was of a far more modest character than that it is now likely to assume; but when its promoters came into contact with the monied men of London whose aid had to be sought, they received advice to launch it on a far larger scale, the support necessary for doing so being, we are told, readily promised, should the verdict of an independent and qualified expert be favourable. It may be rather staggering to old-fashioned mercantile and other colonists in Ceylon, who have hitherto been accustomed to small things only in the way of subscribed capital, to hear that the first digging-machine to be sent out—should the Company float—will cost £5,000! It augurs well for the extent of the operations contemplated that the services of a machine of that class should be from the first thought necessary.

We do not care to "count our chickens before they are hatched," and we admit that all that has been placed before us is prospective only in its character, and is further conditional upon certain preliminaries being satisfactorily established. But we hold the conviction so strongly that all the conditions will be satisfied, that we confidently look forward to an era of greatly stimulated industry with regard to gem mining, and mining generally, in Ceylon. Sir Samuel Baker's anticipations as to the subterranean wealth which Ceylon possesses may possibly ere long receive full justification, and if so, the Colony will be able to claim the most sincere congratulation and will not fail in the expression of gratitude to those by whom it has been earned. We must await further intelligence and the passing perhaps of a considerable period of time—say eight or nine months at least—before we can say whether the prospects which now seem to promise so well, are or are not to be realized. We have little doubt ourselves, however, that at the end of such a term, we shall be able to write of them as being assured, and of an impetus being given to the Mining industry of the Colony which must have for result a great increase to its present prosperity.

SUGAR, COFFEE, AND TOBACCO IN JAVA.

AMSTERDAM, June 19.

The annual reports have been issued of several agricultural companies connected with Java. According to the report of the Netherlands India Agricultural Company, the results of last year do not show much difference compared with those of 1887. Generally speaking, all sugar manufactories in the Java trade are able to work with profit at a marked value of f 8.9 per picul. This is considered as very satisfactory, and has only been obtained by continued vigilance and the most rigid economy, and a more practical and scientific way of dealing with the produce. A discouraging fact, however, is the further extension of the sereh disease, for which as yet no effective measures have

been found to check it. If the cane is suffering to any extent from the sereh disease it is impossible to produce sugar under f. 10 to f. 11 per picul, and consequently a sale price of f. 8 to f. 9 gives an enormous loss. In the meantime the sereh disease has not caused heavy losses to the company this year, and the prospects are not of such a serious nature that the financial position of the company will be seriously prejudiced. The coffee cultivation has also been successful. The prospects of the Pamanockan and Tjassem lands are very favourable. The company's own undertakings consist of the sugar manufactory Kalitandjong, situated in the district of Cheribon, a half-share in the sugar manufactory, Balapoeleng, in Tegal, the sugar manufactory Redjosarie, in Madioen, and the sugar manufactories Ngandjoek and Maritjan, both in Kediri. According to the profit and loss account, there is a net profit in India of f. 317,735, in addition to the commission obtained in Holland and the balance of the past year, making together a total of f. 329,308, which after writing off charges, &c., shows a net profit of f. 291,286. This amount allows the payment of a dividend of 3 23-100 per cent. against 25 per cent. in 1887, while f. 536 is carried to new account.

The report of the Internationale Crediet en Handels Vereeniging Rotterdam has also been issued. The result of the year has not been unfavourable, but business on the company's own account was limited to the small amount of fl. 3,229 exported in cotton goods and other articles. On account of other parties, however, a good business was done, the company having connections with 15 undertakings for coffee, 29 for indigo, and 4 for tobacco, and besides these 16 sugar manufacturers and 1 timber felling undertaking. These undertakings produced to the company 22,537 piculs of coffee, 447,526 Amsterdam pounds of indigo, 3,422,941 Amsterdam pounds of tobacco, 423,600 piculs of sugar, as well as 12,500 piculs of Jacatra sugar, and some lots of cinchona bark, arrack, and spices were consigned to the company's care for sale. Agriculture was not unfavourable during the year. In consequence of abundant rains the ravages of sereh disease are fortunately not so serious, and the company has taken energetic measures to check the disease. The Board of Directors was obliged to write off a total of f. 623,119. From the balance-sheet it appears that the profit is as follows:—Commission, f. 840,479; interest, f. 408,486; sundry revenues, f. 33,275; agricultural undertakings at Sourabaya, f. 13,097; making a total profit of f. 1,402,334, of which was written off:—Sundry debtors, f. 204,096; sundry accounts, f. 2,371; agricultural undertakings, f. 623,119; so that the profit is reduced to f. 227,468, out of which f. 220,000 will be declared for payment of a dividend of 4 4-10 per cent. or f. 2.75 per share, while f. 7,468 is brought to new account.

At the annual meeting of shareholders of the Siak Tobacco Company, Holland, a decision has been come to to liquidate the company; f. 750 will be returned provisionally to shareholders of each paid up share, and f. 50 against each share on which 30 per cent. was paid.

In connection with the reorganisation of the Batjan Company the Company Holland has reserved 1,500 shares of f. 300 in the company, and many of the shareholders have taken advantage of the offer to accept three shares in the Batjan Company for each paid-up share in the Siak Tobacco Company.—*London and China Express.*

LIBERIAN COFFEE CULTIVATION

IN THE PROTECTED NATIVE STATES OF THE MALAY PENINSULA.

This product has been attracting so much attention of late that we asked Messrs. Hill & Rathborne who have several Estates in different parts of the Peninsula to supply us with some particulars of the crops they have gathered, of which we publish a statement.

It is beyond question that Liberian coffee cultivation in the Malay Peninsula is past the experimental stage, and what is most reassuring is the gradual and steady increase year by year as the coffee gets older for:

instance the Linsum Estate in Sungie Ujong gave in 1887 the first year the coffee was in full bearing $6\frac{1}{2}$ cwts. an acre of cleaned coffee; in 1888 just short of 10 cwts. an acre, and up to July 31st of this year $81\frac{1}{5}$ cwts. have already been gathered. The adjoining estate, S'liao, in 1887, the first year (the coffee was all over four years) gave $5\frac{1}{2}$ cwts. of cleaned coffee to the acre, in 1888 it increased to 11 cwts. per acre, and up to July 31st of this year $6\frac{2}{3}$ cwts. have been taken off the Estate.

In Selangor there have been equally satisfactory results. Weld's Hill Estate in 1887, the first year the Estate was in full bearing, gave $7\frac{1}{2}$ cwts. an acre, in 1888 close on 9 cwts. per acre and this year up to July 31st it has already given $7\frac{1}{2}$ cwts. per acre.

Batu Caves Estate in Selangor, when the coffee was under 4 years old, gave 5 cwts. an acre, and this year up to July 31st it has already given $4\frac{1}{2}$ cwt. an acre. So important did we consider this information that we personally visited Messrs. Hill and Rathborne's office where they kindly allowed us to examine and verify the above figures from their report and account books.

Such magnificent results from Liberian coffee, coming as it does after the collapse of the Rawang Tin Mine, will go far towards proving what we have so consistently maintained that in the Straits Settlements there is a fine field for the investment of Capital in planting and agriculture, when guided by experience and forethought.

What we believe is essential to the future development of agriculture in the Straits is that every facility should be given to Indian labour to come to the Straits, and that advances given in India should be recoverable in the Straits, and that the agricultural labourer should arrive as a free man, who can, if he feels so disposed, refund any monies he may have received, and after giving one month's notice to his employer, may be free to go elsewhere. We believe the coffee planters are ready and willing to give 23 cents or equal to $51\frac{1}{2}$ rupee cents per day for good labourers.

At present the monopoly of recruiting for the Straits is in the hands of a few people, and respectable recruiters going from the Straits to bring their fellow-villagers are often arrested on trivial pretexts, and locked up in the Police stations. When released they come out but to find their gang scattered, and all their coolies disappeared.

The present restraints and difficulties which surround the Indian Agricultural labourer leaving his country to go and better himself in a neighbouring Colony under the same Government, are scarcely credible, and a grave responsibility rests upon those who direct our Imperial policy when such an anomaly exists of thousands nearly starving in one portion of Her Majesty's dominions and Indian finances seriously imperilled thereby, while in another and not distant portion of the same dominions, employers of labour are clamouring for constant further supplies, which demand is met, though inadequately, by a continuous influx of Chinese. These take away their earnings and spend them amongst an alien race, whereas the loyal Indian subjects of Great Britain, who are also better customers of English manufactures are prevented by a paternal government from coming freely to the Peninsula and participating in its general prosperity which would enable them to remit funds to be spent, among their countrymen in British dominions and thus in a certain measure help to alleviate local distress resulting from the serious famines which too often occur and are naturally so much dreaded.

DELI TOBACCO.—The tobacco estates belonging to Messrs. Naher and Grob have been sold to the Senembah Tobacco Company, whose directors are J. Nienhuys and Dr. Jansen. The Fortuna Estate formerly owned by Mr. Lysius has been purchased by a company for \$15,000.—*Pinang Gazette and Straits Chronicle*, Oct. 4th.

PATENT PLOUGHS AND SUGAR-CANE MILLS.—Mr. A. S. Massey, Engineer and Partner in the Napier Works, Madras, has filed specifications for the construction of light ploughs, and for improvements in sugar-cane mills.—*Indian Agriculturist*, Sept. 21st.

COFFEE PLANTING UNDER SHADE.—We draw attention to the letter of Mr. W. A. Tytler, following that of Mr. J. P. Hunt of Coorg, on this subject. The information given by the latter is well applied by our correspondent today to the circumstances of Ceilon; and we have no doubt from the inquiries made about Coorg seed as well as shade trees, that one and another proprietor will be quietly following the gentlemen who have already begun in Dumbara and Uva, to do a little under new arrangements, with the old staple and favourite coffee. As W. A. T. well says, an average crop from a coffee field is a far more desirable thing than the average return from a tea clearing, both in respect of the less trouble and the better comparative prices.

RELATIONSHIP OF TEA, COFFEE AND COCOA TO PRODUCTS OF TISSUE WASTE.—Xanthine is closely allied to theobromine, the active principle of cocoa, and caffeine of tea and coffee, for the former is dimethyl, and the latter is trimethylxanthine. The stimulating effect upon the brain of cocoa, and to a still greater degree of tea and coffee, is universally known. This stimulating action would lead us to regard them as belonging to the class of products formed during sleep. During the waking hours we might reasonably expect that the substances formed, at least in the early part of the day, would have no narcotic action, even although they should be products of oxidation, but as the day went on the products of waste might gradually assume a more and more soporific character, until in the evening they again produced sleep. If this were so, we might naturally expect that by oxidation of some of the stimulant substances I have mentioned we might get products having no very marked physiological action, and others having a narcotic action.—*Pharmaceutical Journal*.

ALL ABOUT RICE.

(From "Days with Industrials," by ALEXANDER H. JAPP, LL.D., F.R.S.E.)

"One half the world," it is said, "knows not how the other half lives." One half the human race have rice for their food-staple, and yet we in this part of the world know on the whole very little about rice, its history, its mode of culture, its many varieties, and the processes through which it passes before it is placed upon the table. We see it in the shop or in the store at home, and it is one of the "familiar good creatures" of our life; but if we knew more of it we should esteem it more highly, and probably extend our use of it largely. At the present time, when, owing to various influences the supply of native grain is so limited, it may be more than usually interesting to be made somewhat better acquainted with the merits of a staple which for the last twenty years has been rapidly making way on the Continent, but which has not yet by any means got the position it so well deserves amongst us. Our interests and its claims are luckily identical; and therefore we have the more faith in our right to request our reader's close attention, particularly if he is a social reformer, concerned for economy and the comfort of the masses. We shall therefore try to begin at the beginning, and follow the rice from the first to the last.

Rice is a cultivated variety of aquatic grass, bearing when in the ear a nearer resemblance to barley than any other of the English corn plants, and it reaches about the same height. The seed grows upon separate pedicles like the oat, each springing gracefully upwards on a hair-like stalk from the main stem. The seed is enclosed in a rough yellow husk, which in some varieties terminates with an awn, or beard, like barley; other varieties are awnless.

There is little reason to doubt that the rice-plant is of Indian origin, for in India it is now found growing in a wild state. Tradition says it was introduced thence into China about 3000 B.C., but its use and introduction into Europe are far more modern. It was first introduced into Spain by the Moors as recently as the twelfth century. The derivation of the word from the Sanscrit, *vrihi*; Tamil, *arisi*; Arabic, *aruz*; Latin, *oryza*; Italian, *riso*; English, *rice*, very probably suggests the route in which the cultivation of the plant has extended from its Indian home. It is certain that rice was not known in Italy in Pliny's time, 60 A.D. In describing the foods of India he says:—"But the most favourite food of all these is rice, from which they prepare 'ptisan' (pearled or clean rice), similar to that made from barley in other parts of the world. The leaves of rice are fleshy, very like those of the leek, but broader; the stem is a cubit (18 in. high), the blossom purple, and the root globular, like a pearl in shape." (Book xviii. chap. 13.)

This description clearly proves that Pliny had never seen the plant itself. He goes on to say, "Hippocrates, one of the famous writers of medical science, has devoted a whole volume to the praises of 'ptisan,' the method of preparing which is universally known." Pliny does not give rice among his list of plants cultivated in Egypt, but Wilkinson considers it was cultivated in the Delta; and the pictures in the Theban tombs of the cultivation and manufacture of a grain where the processes are the same as to-day practised in India in rice cultivation confirm Wilkinson's opinion.

The Karens (an aboriginal race in British Burma) have an account of the Creation, which is of undoubted antiquity, and to this effect:—"The Father, God, said, 'I love these, my son and daughter; I will bestow my life upon them.' He took a particle of his life and breathed into their nostrils, and they came to life and were man. Thus God created man. God made food and drink, rice, fire and water, cattle, elephants and birds." (Forbes's "Burma," 1878.)

Rice has perhaps more cultivated varieties which differ more from each other than any of the cerealia. The Karens have names for forty varieties. Dr. Moon mentions one hundred varieties growing in Ceylon. Besides these, there are the different kinds growing in China and Japan and other parts of the world. They are of every colour, from ivory white to coal black.

The grain varies in shape from cylindrical to globular. Some varieties are sweet, some oily, some soft and chalky, others hard and translucent.

With reference to the mode and time of growth, there are four main varieties in cultivation—common rice, early rice, clammy rice, and mountain rice. Common rice, the variety cultivated in British Burma, is the strongest plant and gives the largest yield, for one crop about twenty-five-fold, and takes six months from ploughing to harvest. Early rice grows mostly in China and India, and takes three or four months to mature. Mountain rice grows on the Himalayas, sometimes pushing its way through the snow, and without irrigation reaching maturity in ninety days. Clammy rice (*Oriza glutinosa*) has the advantage of being able to grow on wet or dry land, and ripens in about five months.

The rice-plant is distributed over the earth as high as the 45th parallel N. and the 35th S.

It is the main crop of China, Japan, Burma, Cochinchina, India, Madagascar, Java, and Italy, and is extensively cultivated in North and South America.

Wild rice is still eaten as a luxury on the Madras coast: it has a small white grain, very sweet; it grows on waste marshy lands. The only reason it is not cultivated is because it returns so small an increase as compared with the cultivated varieties of the same plant.

Although rice was introduced into Italy so lately as the thirteenth century, its cultivation on the rich meadows of Lombardy, watered by the Po, and other similar flat lands, has so increased that the Italian rice-crop of 1879 amounted to no less than 500,000 tons. It is the most profitable crop to the cultivator of any that is raised in Italy; but the same unwholesome effect of malaria from irrigated lands is experienced there as has proved so fatal in Carolina, and the Government has found it expedient to place its cultivation under great restrictions. This circumstance, together with the extra taxation on rice, would have destroyed any other culture save one that offers the only means of profitably cropping swampy and marshy lands.

Rice-culture in Carolina and Georgia and the adjoining State, which attained to such a high degree of excellence, dates only from about the year A.D. 1700. White rice was introduced from India by Mr. Dubois, Treasurer to the East India Association, and the red rice was brought from Madagascar. It is said that it was taken by accident by a sea-captain, who gave some of the "paddy" to a Mr. Woodward. After its value was discovered the captain was handsomely rewarded for the service he had done the country.

The rice, by careful selection and cultivation in trenches—instead of being sown broadcast—has made the Carolina plant so famous that the seed has been exported to Java, Madras, Spain, and Italy, and some of the finest modern varieties of Indian rice are grown from Carolina seed.

Since the American war and the abolition of slavery the rice export trade from America has practically ceased. The crop in 1870 was only 73,000,000 lb. against 250,000,000 lb. in 1850. This is because the free negroes object to work in the swampy rice-fields, associated as they are with fever, malaria, and sickness.

The cultivation of the varieties of common and early rice throughout India and China are very much alike.

The fields are carefully levelled and divided into squares, surrounded by low embankments about eighteen inches wide, and the same height, which fall gradually from the level of the source of supply to that of the drainage-cut, which carries off the surplus water. In some instances, as in Southern India and China, crops are raised which depend in the main on artificial irrigation—the water being raised by manual or animal labour from a tank or river, but generally the natural fall of the country is taken advantage of to save this extra expense.

The fields are cleared of weeds; then, when the rains have begun, they are ploughed or scratched with a simple wooden plough while they are a foot or more under water, the ploughman and his buffaloes being sometimes knee-deep in slush.

The "paddy" intended for seed is placed in large baskets under water for a few days to let it germinate. When it has sprouted and is known to be good, it is

sown broadcast on the surface of the water by men who stand upon the embankments on those fields that are to be used as a sort of nursery for the rest of the land. Probably this process is referred to in Ecclesiastes: "Cast thy bread upon the waters: for thou shalt find it after many days."

When the young rice has pushed its way through the water, and is about eight inches high, the labour of transplanting from the nurseries to the rest of the farm lands must begin.

The plants are pulled up, roots and all, and piled in large baskets and taken to the fields where they are to be finally transplanted. The operation is generally carried on in the midst of heavy rain, the labourers standing up nearly to their ankles in water and slush, and the stooping posture all day long makes the work very arduous. They protect their heads and bodies with a sort of umbrella or thatch made of palm-leaves. Thus attired, the worker presents rather a comic appearance when seen for the first time, looking from behind not unlike a crab or tortoise walking on its hind-legs. The women and children are engaged in planting out, and half the village will turn out to plant for *Tulsi Das* one day, and *Hurri Pandoo* the next, and so on, each helping the other in proportion till the whole of the fields are planted.

The transplanting process is thus described:—

"A bundle of seedlings being laid across the arm of each person, all standing in a row, a couple of the young plants are disengaged from the bundle with the right hand and stuck in the ground, or rather mud, in rows about a foot apart, with the same distance between the plants. Sometimes a forked stick is used, with which the plants are deftly drawn from the bundle and planted with a slight thrust in the soft soil; this obviates the fatigue of the stooping posture when the hand only is employed. The operation proceeds at a rapid pace, the seedlings being put down almost as fast as one can count. After the transplanting no further care is given to the crop until it begins to ripen; no weeding is ever thought of, nor is any manure ever applied to the ground before planting; all is left to nature.*"

Archdeacon Grey, in his book on China, has given the following very picturesque description of a rice-field at the various stages:—

"So quickly does the rice-plant grow, that in the course of a few days the whole country presents a rich green appearance. Perhaps one of the most charming scenes on which I ever gazed was the vale of Mantsu, in the island of Formosa, seen from the slopes of one of the neighbouring mountains when the rice-plants were putting on the fresh green of their early growth.

"After the rice has been planted the farmer must see that his lands are well supplied with water, for a scarcity of that element would prove fatal. In general the rains, which fall at such seasons in heavy showers, are enough for this purpose. The labourer must watch the plants carefully lest they should be destroyed by noxious weeds. A labourer who observes a weed growing in close proximity to a plant immediately removes the latter, so as to destroy the weed, after which he replaces the plant. It is the duty of other labourers to gather a kind of worm, like our common earth-worm in form and size, and said to be very destructive to the rice-plant. These worms are not thrown away, but conveyed to the various markets, and sold to ready purchasers as a delicate article of diet. There is also an insect resembling a grass-hopper by which the rice-crops in China are often in danger of being blighted or destroyed, and which flies about in large numbers.

"When the rice is ripe unto harvest—generally in the month of June, *i.e.*, one hundred days after it was first sown—the reapers come upon the field. Each reaper is provided with a sickle, which bears a strong resemblance to the reaping-hooks in use in Great Britain. In some of the agricultural districts reapers gather only the tops of the ears of rice. To this mode of reaping grain a reference is made in the Book of Job (xxiv. 24), where it is written, 'They are taken out of the way as all other, and cut off as the tops of the ears of corn.'

* Forbes's "British Burma, 1878," page 104.

And again in Isaiah (xvii. 5), 'And it shall be as when the harvest-man gathereth the corn, and reapeth the ears with his arm: and it shall be as he that gathereth ears in the valley of Rephaim.' According to this mode the ears are cut off near the top, the straw being left standing. As it is cut the grain is bound into small sheaves, each of which is placed on the ground in an upright position. In this position, however, the sheaves are not allowed to remain for any length of time; they are threshed then and there by labourers, who take them in their hands and strike them with force against inner sides of tubs, into which, of course, the grains fall. Certain kinds of rice, however, cannot be threshed in this way; and it is customary for the labourer to carry the sheaves of this rice to the homestead on bamboo rods, so that they may be threshed there by mills. The threshing does not take place in a barn, but on a threshing-floor, with one of which every farm is provided. Before the sheaves are laid on this floor is very carefully swept. To this careful cleansing of the threshing-floor an allusion is surely made in the Gospel of St. Matthew (iii. 12), where St. John the Baptist describes our Lord as one 'whose fan is in his hand, and he will thoroughly purge his floor, and gather his wheat into the garner.'

"According to the Book of the Prophet Isaiah (xxviii. 27) and the Book of Ruth (ii. 17) this mode of threshing grain is very ancient. It would appear, however, that the Hebrews principally used the flail in threshing small quantities of grain, or for lighter kinds, such as vetches, dill, or cummin."

We must, however, introduce one or two details omitted by Dr. Grey. The rice-fields are weeded once or twice before harvest; all the villagers help each other, as they do at transplanting, so as to complete the whole of each field at the same time. The fields are kept covered with water until about fourteen days before harvest, when the supply is cut off and the grain ripens and turns yellow.

Perhaps one of the finest sights earth can show is often to be witnessed when the rice ripens, though it is a great grievance to the husbandman: flocks of birds, green parrots, and crowds of other varieties come in such immense numbers, that were the crops not closely watched from early morn till night there would be little left to repay the cultivator for his labour. Boys are perched up in small pigeon-house-looking structures on the top of bamboo poles some sixteen or eighteen feet high, for protection from wild beasts. Here they scream and yell all day long, besides having loose bamboo rattles attached to cords, at different parts of the field, tied to one rope, which they pull occasionally. Even this is not always effective; for instance, Carolina rice cannot be grown in Burma because it ripens some six weeks sooner than the general crop, and the birds manage to carry off so much of the isolated patch, when they can get no other, that its cultivation has in consequence been abandoned in the few cases in which it has been tried.

In British Burma rice can be so cheaply cultivated, and the land is so well adapted for its growth, that this has in the last thirty years become the centre of the rice-supply of the whole world.

The rainfall is so heavy that the whole country is inundated completely from one range of hills to the other. The only traffic that can be then carried on is in boats. The villages are built either on piles or on elevated clumps of land, and cattle are stabled and grain stored, and the people live, during the rains, in a condition not unlike that which existed in the time of the lake-dwellings.

The heavy rainfall flooding the whole country enables the cultivator to dispense with those expensive husbandry operations—such as levelling the fields, making embankments, &c.—which are so necessary in other countries. The Burmese do not even observe the rotation of crops or manure the land. On the other hand, they crop the land only once a year; while in China and parts of India three crops are gathered—two of rice and one of other grain. It is common, indeed, in many parts to take two crops of rice off the same land in one year. Mr. Crauford, a good authority, says that he has seen fields which have produced two

crops a year from time beyond the memory of any living person, and that in some particularly favourable spots they manage to get six crops in two and a half years.

The Burmese main crop consist of varieties of the "common rice" that ripens in six months. It is sown about June, and gathered in December following. The nursery grounds are sown on the higher land at the beginning of the rains, before the ground is ready for the main crop. When the plants are about eight inches high they are pulled up, roots and all, and tied in bundles, and carried by the boatload to supply those cultivators who are ready to plant out their land. The "paddy" lands are prepared for being planted by being lightly ploughed with a wooden plough, while they are under water, after the rains have set in. The crop is reaped with sickles, but only the top of the stalk with the ear is cut off; the straw and stubble are left standing till spring-time, when they are burnt, which gives the land in Burma the only manure it ever gets.

After harvest the grain is carted to the dry earthen threshing-floor, and either stacked or threshed out then and there, sometimes, in China and Japan, with flails; but generally, as in Burma, it is trodden out by oxen. The "paddy" is laid in a circle in the centre of the threshing-floor, and the oxen, tied together in line, are driven round the heap, the herdsman following with a stick, still singing on his way, as in the old harvest scenes depicted on the Theban tombs some three thousand years B.C. And still carrying out ancient command, they do not muzzle the ox that treadeth out the corn.

The "paddy" is then stored in granaries, which in Burma are raised on piles some feet above the surface of the ground, built of bamboo wattle and daub. In China, where grain is very extensively stored throughout the empire as a provision against famine, the granaries are larger and of solid masonry. From them seed is lent to indigent farmers in the spring-time, to be recovered with interest after harvest. The Chinese mix the ash of the burnt husk with the stored "paddy" to preserve it from weevil, for which it is said to be effective.

The "paddy" is next shelled by being passed through a small pair of millstones or cylinders of the same shape made of hard wood, set on end, grooved in the working surface. These work at such a distance apart as serves to remove the husk by friction without breaking the grain. And they are generally made large enough to require three or four men, who work them by means of a long handle or connecting-rod attached to the upper cylinder.

The grain and chaff are separated by being dropped together from a height in a light breeze, recalling the description in the 1st Psalm, of the ungodly who "are like the chaff which the wind driveth away." Or the grain is tossed up on bamboo trays with wooden shovels against the wind. In China, Japan, and Burma, however, the winnowing-machine, made on the English system by Chinese carpenters, is rapidly replacing the older method; just as in the Burmese and Oochin China rice-ports the European steam machinery for shelling and winnowing is daily diminishing the quantity of the hand-cleaned article.

After the rice is shelled, inner skin adhering to the grain must be removed which is done by pounding it in a wooden or stone mortar with hard wood beaters, until the friction has entirely removed the outer skin.

This process must not be confused with that of pounding or pulverising in a mortar. The pestle or beater is of another shape, and the mortar holds a larger quantity of grain at a time, so that the impact of the beater will not break it. It is referred to in Proverbs xxvii. 22: "Though thou shouldst bray a fool in a mortar among 'grain' with a pestle, yet will not his foolishness depart from him." Had our translators known the mysteries of rice and barley milling, they would not have translated the word as "wheat," which means literally "decorticated grain," or as Herodotus and Pliny call it, "ptisan"—a process never applied to wheat.

There were in 1877 forty-five steam rice-mills in British Burma, which are mainly worked for the pre-

paration of cargo rice, *i. e.*, four parts by measurement of husked rice to one of paddy, in which condition most of the Burmese crop is shipped to Europe. These mills have lately been introducing machinery for making "cleaned rice." This enables them to supply the Burmese with cheaper rice than they can clean by hand, besides supplying direct a large foreign trade which, until lately, was in the hands of the English millers.

There are few busier scenes than the port of Rangoon in the height of the shipping season. What with the cargo boats coming down the rivers bringing "paddy" to the mills, the coasting dhows and steamers taking away the cleaned rice to the Straits, China, and India, and the large sailing ships and steamers loading for Europe and Australia and America, the people have a busy time of it. The mills work night and day, and no one who has seen the Burmese labourer running along with a two-hundredweight bag of rice on his shoulders, working in a hot sun and for long hours, will preach the usually accepted rubbish that mankind cannot labour and thrive on a diet mainly composed of rice.

The rice-milling process of the English rice-mills in London and Liverpool is but a modification and repetition of the processes already described, carried out with greater detail and with self-acting machinery. The five-part cargo rice is brought from Burma in two-hundred-weight bags; these are unloaded at the docks and carted to the mills.

They are emptied into a bin, whence the rice is elevated by an endless band called an elevator, with small cans attached, to the top-storey of the mill, and passed through a sieve to free it from sticks, stones, straw, and sometimes a rupee or a broken bangle.

Then it passes through the shelling-stones. They are large millstones, six feet in diameter, revolving 120 revolutions per minute, dressed hollow in the centre and flat for twelve inches at the rim, where they are set the length of the grain apart, so that as the rice passes through this narrow space the husks may be cracked off with the least possible breakage to the grain itself. The chaff, meal, and rice from this process pass through a screen to remove the meal; then a fan or winnowing-machine is used to take out the chaff, and the rice is ready for being "barley milled."

The barley-mill, as its name implies, is a modification of the well-known machine used throughout Europe for making "pearled" barley. It consists of a circular cheese-shaped stone, four feet in diameter and two feet wide, which revolves very quickly inside a slowly revolving wooden casing covered with fine wire-netting. About five-inch space is left on all sides between the stone and the casing, which is partly filled with rice, and the machine is started.

After barley-milling, the rice is again elevated to the top of the building, and passes down through two or three polishers. They are inverted conical wooden drums about four or five feet in diameter and six feet deep, covered with sheepskin with long wool outside. They revolve about two hundred revolutions per minute inside a fine wire-covered casing of the same shape, which is firmly secured in its place, leaving small space between the woolly surface of the drum and the casing. As the rice passes through this space the meal adhering to it is driven through the wire and the rice is polished.

It is then winnowed once or twice to remove any remaining husks, and it finally passes over a sieve which is kept moving with a quick kind of shake, and which is set at a slant from top to bottom and with holes graduated in size. This separation is effected into whole rice, and middling broken, and small broken rice, known as "smalls."

During the twenty-five years from 1854 to 1879 the increase of consumption is something altogether marvellous, and (taking into consideration the liability to fluctuate) it has been marked and steady, as any one who notes the following figures will at once perceive:—

In 1854 the total quantity of rice exported from Burma was 69,820 tons, all of which was Akyab rice; in 1862 it was nearly trebled, being 191,861 tons, of which 64,785 were Rangoon, 98,751 were Akyab, and 28,325 Bassein. In 1870 the increase, though not so

great as that of the former eight years, was still considerable, the total being 294,673, of which 170,306 tons were Rangoon, 80,295 Akyab, 34,206 Bassein, and 9,866 Moulmein; showing that while the Akyab had decreased by 18,456, the Rangoon had considerably more than doubled its total number of tons. During the next nine years (1879) the totals are 594,500, showing an increase of 524,680 tons for twenty-five years.

In all probability the time is not very distant when the bulk of Burmese rice will be conveyed to European ports by the rapid and safe agency of steam vessels. It seems that about five-sixths of the rice imported into England is shipped from Burma, the quantity of rice shipped from the ports of India being comparatively small.

During the year 1880 the exports from Burma into Europe reached 617,000 tons, viz:—

To Great Britain	315,000
To the Continent	302,000

617,000

It would thus appear that the people on the Continent are more of a rice-eating race than we are in Great Britain, as the former consume nearly all that they import, whereas a large proportion of the imports into Great Britain are again exported in its cleaned state to different countries. It is calculated, indeed, that nine-sixteenths of the crop sent to Europe is disposed of on the Continent.

We shall now glance very shortly at some peculiarities of the different kinds of rice. Patna rice takes longest to boil; it is hard and brittle. Java is similar, very highly finished and pretty to look at. Carolina is like Java in appearance, but hardly any is now imported to England. That sold as such is either Java or "Paris dressed" rice, *i. e.*, some other rice polished with beeswax to make it look like Carolina. Waxed rice seems a curious thing, yet it is now in the market. It appears that one or two per cent. of beeswax adds a peculiar lustre to rice, and makes it look so pretty that the Dutch are profiting much by preparing it for English use. So much favour, indeed, does this waxed rice receive over the plain and genuine article that Carolina rice is actually sent over from England to Holland to be waxed, and is returned to England in its "transformed deformed" condition to be sold at a high price as the finest Java. So much do appearances avail in such matters, and so gullible is the English public even in the all-important matter of food. Much that has been written against the food value of rice (which in reality shows only the necessity of a *mixed* diet) may be disposed of by showing the estimation in which it is held as a food by the people who eat it. In Southern India a working man indicates his prosperity by telling how often he can afford to eat rice, "once or twice daily, or weekly." Or to take larger statistics, the Burma export during the last thirty years has increased by £9,000,000, and the Italian crop last year was valued at £5,000,000. If the proof of the (rice) pudding is in the eating, these figures showing the increasing popularity prove a great deal.

The consumption in England, as we have seen, is small as compared with that on the Continent. Here it competes with potatoes; people do not like to pay twopenny per pound for rice when potatoes are a penny, but some shrewd housewives have found out that potatoes at the same price as rice are four times as dear, and here is the scientific proof of it:—

	Water.	Flesh-formers.	Starch, &c.	Total Food.
Rice	13	6.5	80	86.5
Potatoes	75	1.4	22.6	24.0

This shows that 1 lb. of rice contains $3\frac{1}{2}$ times as much food as 1 lb. of potatoes. Taking into account the loss in peeling potatoes, 1 lb. of rice is worth 4 lb. of potatoes; and, as rice absorbs three times its weight of water in boiling, the 1 lb. of rice, costing *d.*, when boiled equals 4 lb. of potatoes, costing 4*d.*, in bulk and weight, and exceeds them in food value.

Hassall states that rice is the most easily digested food known; it will disappear in the stomach in one hour. The smallness and regularity of its starch-grains probably give rice this valuable property of being so easily digested. It is therefore, very remarkable that rice flour, the most valuable of all the farinas in food

value, cheapness, and digestibility, which is so much used in America and in France as food for invalids and infants, where it is known as *Creme de Riz*, is almost unknown in England for the same purposes. Its value may be seen by the following table:—

	Flesh-formers.	Starch.	Price per lb.
Corn flour	...	0	100
Arrowroot	...	1	99
Tapioca	...	2	98
Rice flour	...	6.5	93.5

If it were only patented as a food for children and invalids, and called by some Greek name, it might possibly command a ready sale.

Sufficient attention has not been called to the danger of feeding children exclusively on those "starch foods" that contain little or no nitrogenous matter. Dr Bartlett, in his evidence before the Adulteration Committee of the House of Commons, in 1874, stated that numerous instances of children reduced to skin and bone from being fed with corn flour had come under this notice.

Rice flour, which might well be used for food, has a prejudice against it, and in England is used principally for "sizing" Manchester goods. It is sought after however, for mixing with wheat flour for bread-making both to bring up the colour and in times of a damp harvest as an "absorbent," to improve the rising properties of the bread flour. Granulated or "ground rice" is made by crushing rice small between smooth iron rollers. It is used only for making light puddings and confectionery.

Rice meal is used for cattle, poultry, and pig feeding, never for human food, because the taste is bitter and unpalatable. It is so little known, as compared with Indian meal that although its food value, as shown below, is better, it can be generally bought at two-thirds, the price—*i. e.*, when Indian meal is quoted at 6s, rice meal can be bought at 4s.

	Rice Meal.	Indian Meal.
Moisture	...	8.80
Oil and fatty matter	...	9.50
Albuminous compounds	...	12.75
Starch, cellulose, &c.	...	64.85
Ash	...	4.00
		1.50

In some markets—Derbyshire, for instance—rice meal has all its own way; in Yorkshire it is almost unknown. The British farmer has a prejudice against feeding his stock on food that his ancestors have not used before him. Indian meal has had a long fight for it. Rice meal is competing, and in good time its cheapness and food value will be recognised.

Lastly, the husk. Such husk as is quite clean and free from rice meal and rice is sold partly for Holland, where it is used for packing gin and hams. It is more elastic than sawdust, and does not so readily shift in the packing-cases with the motion of travelling. Part is ground into fine meal for the provender dealers, who use it for mixing with linseed cake, Indian meal, rice meal, and other feeding stuffs, and a large quantity is exported to the Continent yearly for the same purpose. The coarser ground strude, called the strude bran, is sold for polishing tin plates, the large amount of silica it contains making it valuable for this purpose. As ground strude contains only fifty per cent. of feeding matter, a small proportion added to rice meal soon brings down the food value. If farmers were to consult their interests, they would buy rice meal either direct from the maker, or, if from a dealer, on a given analysis guaranteed, then a pure article and money value could be depended upon.

FINE VS. MEDIUM PLUCKING OF TEA

The remarks of "Sigiriya" on this subject are interesting, but we regret that he should elect to take no part in the discussion because we and many of your correspondents have arrived at the conclusion that the system of fine plucking is altogether indefensible. As regards the test to which we alluded, where a gang of fifty coolies were divided, half being ordered to pluck fine and half as usual, no sort of test was sought to be made of the case as to the quantity of leaf likely to be obtained by the two different systems,

as our correspondent supposes. We call attention to the figures, not as indicating the exact quantity of tea likely to be obtained by fine and medium plucking, but to show that the Souchong leaf was plucked with very little cost indeed to the estate. Granted that the difference in quantities plucked is not really so great as was shown by the figures we quoted, there still would be a difference, and a very considerable one, too, seeing that our correspondent reckons the falling-off in quantity brought about by the abandonment of medium for fine plucking at "between 60 to 80 per cent"! A gang of trained coolies plucking fine would go over a larger area possibly in a day than a gang plucking medium. They would bring in very much less leaf, and they would go round the estate, say, four times a month, instead of, say, five times in two months. We are well aware of this, of course, but it does not affect our contention in the slightest. Another point, and a very important one, is the effect on the trees caused by a long continued course of fine plucking. Our correspondent ridicules the idea that it has anything like such deleterious effects as are supposed. Experience alone will prove whether this is so or not, but the result must depend on varying conditions—such as the altitude of the estate, the age of the tree, etc.—and there is a very great consensus of opinion that fine plucking—if continued long—has a detrimental effect upon the trees. However that may be, the case for medium plucking does not rest on the settlement of this point solely. Even were it indisputably proved that the tree is no more affected by one system than the other, we should yet require those who advocate a departure from customary methods to show us how it would be advantageous to do so. It should be remembered that it is not *we* who are proposing any novelty. In face of falling prices, and after a careful examination of the *pros.* and *cons.* of the case, we say that we do not see how it will benefit us to change the existing methods of plucking. If we are mistaken, it is surely the duty of those who differ from us and who advocate a complete change of system throughout the island, to prove to us that it would be advantageous to do so. As yet we have not seen any figures tending to support this view, although we have published many which go to controvert it. Of course everything, as we have repeatedly pointed out, depends upon the falling-off in yield which fine plucking brings about, and the increase in price obtained for the tea. Our correspondent "Sigiriya" put the following-off in quantity at from 60 to 80 per cent., which is very much higher than we estimated it, but he does not give us his idea as to what increase in price may be expected. With so enormous a falling-off in quantity, however, it is obvious that a very large increase in price is looked for. Let us then allow for it fully, applying it to the figures already published by us, which have this advantage, that they are not hypothetical, but are those of an average estate at a medium altitude. This estate gives 300 lb. an acre, gets an average of 55 cts. for its tea, and makes a profit of 25 cts. on every lb. of it, which as things go nowadays is very good. Assuming, therefore, that the falling-off in quantity by fine plucking would be 70 per cent. and that the price realized all round for the tea is as high as *R1 per lb.*, the following is the result:—

MEDIUM PLUCKING.—200 acres @ 300 lb.			
60,000 lb. tea @	55 ct.	R33,000	
Costing @	30 ct.	R18,000	
	Profit	---	15,000
FINE PLUCKING.—200 acres at 90 lb. an acre.			
18,000 lb. tea @	R1	R18,000	
Cost @	60 ct.	R10,800	
	Profit	---	7,200

Difference in favor of medium plucking 7,800
 "Sigiriya" would say that as much as *R1.25* per lb. might be counted from such fine plucking, given a good jaf of tea and careful manufacture, but even if we grant that for the sake of argument, we still find that the profit made is less than by the old system of medium plucking. We again give the figures for comparison:—

MEDIUM PLUCKING.—200 acres at 300 lb.			
60,000 lb. tea @	55 ct.	R33,000	
Costing @	30 ct.	R18,000	
	Profit	---	15,000
FINE PLUCKING.—200 acres at 90 lb.			
18,000 lb. tea @	R1.25	R22,500	
Costing @	60 ct.	R10,800	
	Profit	---	11,700

Difference in favor of medium plucking 3,300
 Now does anybody suppose that with a yield of 90 lb. per acre the cost of production could be kept down as low as 60 cts. per lb? The fixed charges on an estate, including the superintendence, weeding, plucking, etc., would come to quite *R36* per acre, equivalent to 40 cts. per lb. of made tea at 90 lb. the acre, while manufacture and transport to Colombo would cost more than 30 cts., so that the total cost of a lb. of tea at this rate would be over 70 cts. a lb., and this would still further increase the difference in favor of medium plucking.

In this matter we are only anxious to arrive at a just conclusion, and to ascertain the best course for the community as a whole to pursue; and if we have omitted to take into consideration any facts which would upset our calculation, then we should be very glad to have them pointed out. In reference, however, to the hypothetical case of fine plucking we have quoted above, we think it will be admitted that we have placed it in as favourable a light as possible. We can hardly believe that as much as *R1.25* could be reckoned on even for the finest plucking coupled with the most careful manufacture, except in an exceptional instance, and certainly it could not be calculated on if the generality of estates took to plucking fine, for then such teas would be plentiful and prices would fall. Of course, there are exceptional cases when it pays to pluck fine.

(To the Editor of the "Times of Ceylon.")

SIR,—So many of your correspondents have attacked fine plucking so vigorously while you yourself seem to have fully arrived at the conclusion that the system is altogether indefensible, that I propose to hold aloof from the discussion as to the relative merits of fine and medium plucking.

I would merely draw your attention to one or two points. One of your correspondents put on two gangs of coolies of equal number—one with orders to pluck as usual, the other to pluck fine—and drew from the result the wonderful conclusion that his usual plucking paid best. Now, does he really believe that the test was a fair one, or has he, together with yourself, overlooked the fact that the winning gang were plucking as usual and the losing gang were quite new to their work?

Having some experience in the education of coolies to pluck fine, I may state that I find as a rule coolies new to the system plucking about 50 per cent. less on the first day, and that they take a full month or even more to get into the swing with the regular pluckers. Even supposing your correspondent's test to have been a fair one, the value of tea manufactured from the fine leaf is fully 25 per cent. too low for properly manufactured tea.

I do think, in the interests of all concerned, who desire a sound knowledge as to the merits of the various systems, that all such unreliable tests should be discarded; and it certainly surprised me to see such a worthless test made the basis of so much construction in favor of coarse or medium plucking.

How many have taken it upon themselves to state as a fact that fine plucking is ruinous to the tea bushes, I should be afraid to say, but I have seen this statement made over and over again, accompanied with no small measure of ridicule. Such random statements are no doubt easy to make, and give the maker a certain air of importance as an authority on the subject, and moreover they are difficult to controvert; but those who really wish to arrive at the truth would like to see such statements supported by something more than mere ridicule.

Tea plucked fine for over 3 years should, I suppose, be on the verge of dissolution; it would be folly to attempt any proof to the contrary; but you, Mr. Editor,

or anyone else who wishes to see the result of the system should see these things for yourselves, and draw your own conclusion from *real* facts. In direct reply to your query, the loss of leaf is from 60 to 80 per cent, taking adjoining estates for comparison.

—Local "Times."

SIGIRIYA.

MINING IN THE MALAY PENINSULA.

To the Editor of the "North-China Daily News."

DEAR SIR,—The collapse of the Rawang Mine in Selangor affords an opportunity of mentioning a fact which is apparently only known to a very few of the investors in the mining ventures in the Malay Peninsula, who reside in China. It is this; that the experience gained has shown that what is true in other parts of the world is equally true in regard to the Malay peninsula, viz., that *alluvial* mining will pay Chinese but will not pay Europeans, and that the only kinds of mining that will pay Europeans there, as elsewhere, are either tin lodes, or gold-bearing quartz reefs, at least so far as these two metals are concerned.

When mining engineers first went to the Straits to prospect, a few years ago, they were all aware of this fact as an understood axiom of mining, but they one and all, *i.e.*, those from Australia, as well as those from Cornwall and elsewhere, were so astonished at the apparent richness of the alluvial deposits which they saw being worked by the Chinese in Perak and Selangor, that they thought these were entirely exceptional and would pay European companies. They knew that wherever there are large alluvial deposits of mineral, that there must be a matrix not far off, but they considered that the alluvial deposits were so rich that it was not worth while to take any trouble to hunt for the source, *i.e.*, the matrix, or lode. All the engineers employed by the foreign companies in China, Australia, and England, went to work in these two States on alluvial deposits only. One company only, The Perak Tin Mining and Smelting Co. formed here at Shanghai, secured as a part of its concession a block of land at Selama, then believed to contain a lode, but the engineer who selected it, like all the rest, thought the blocks containing the alluvial deposits so rich that he went to work at these only. Experience has so far shown that this mistake is the cause of all the failures on the part of foreign companies to carry on successful mining operations in the Malay peninsula. Some companies arrived at this result quickly, some slowly, some by the use, more or less, of Chinese methods, but with the same result.

A few of these companies still survive, but without so far as can be learnt, any prospect of lasting success. The Peninsula, from Province Wellesley to Singapore, is one vast jungle with only small clearings here and there where mining and agricultural operations are carried on. The country is however rapidly becoming more accessible by means of roads, and railways, and the improved navigation of rivers. New discoveries are being constantly made, and many explorers and prospectors are at work, under the enlightened and liberal protection of the Straits Government and the Residents of the Protected States. Perak and Selangor having for so many years past exported such enormous quantities of tin, its presence there is a proved fact, but European prospectors are now striving to discover the lodes, or sources from which all these alluvial deposits have come, with a view to working these by foreign companies, leaving the alluvial deposits to the Chinese.

The Chinese in the Straits are far ahead of their nationals in China in mining matters, by reason of their having adopted the use of steam pumps, of which there are now a very large number, owned and worked by Chinese, in Perak and Selangor. They use no other kinds of machinery, but without these pumps they could not have worked even the alluvial deposits. It seems very probable that in the course of time the same sort of experience may be gone through in regard to gold, the presence of which metal in an alluvial form throughout a great part of the peninsula, has long been known. Efforts are being made at present to discover gold-bearing quartz reefs, in the

neighbourhood of the places where alluvial gold can always be found. It is extremely probable that such reefs will be found, and if foreign companies work them and leave the alluvial deposits alone there is no reason why they should not be as successful there as in Australia, and other parts of the world. It is stated that already gold-bearing quartz reefs have been found, and an Australian company has been started to work one of these with a capital of a million. The famous Mount Bischoff tin mine in Tasmania which, for so many years, has paid dividends of about four hundred per cent per annum upon its paid up capital, is a lode mine worked upon the most scientific system by foreign engineers, with foreign machinery, and has achieved this wonderful success although it is situated at an immense distance from the English market, has to pay very high rates of wages, and is said, by mining engineers who have visited it, to work upon produce which does not contain a very high percentage of tin. No such success (if in fact any success) has been achieved by the attempts to work the alluvial deposits of tin found in certain parts of Australia. The same moral may perhaps be not inaptly applied to China. That coal and mineral deposits of great extent and richness exist in China is universally believed. The Chinese have worked some of these in various parts of the Empire probably for ages past, and are doing so now, but all their working is mere surface scratching, and not mining at all. They have no appliances for pumping, and therefore cannot get more than a few feet below the surface, and they have no appliances for crushing mineral-bearing rocks, and therefore cannot deal with lodes, or reefs. The consequence is that although a large amount of metal has been slowly and expensively obtained from alluvial, or surface working in various parts of China, the real mineral wealth of the country is still untouched, and must continue to be until trained engineers, and suitable machinery are employed to develop it. There is now only one scientifically made and successful mine in China—the Kaiping coal mine in the north of China—made by Mr. Tong Kinsing with the assistance of foreign mining engineers, and by means of foreign machinery.

Now that railways have been sanctioned it is reasonable to expect that the Government will soon take steps to realise some of the enormous wealth that lies ready to their hands by developing the coal and mineral resources of the country in the only way in which such resources can be developed, viz., the formation and working of real mines by means of skilled engineers, and suitable machinery.—Yours, etc.,

W. V. DRUMMOND.

Shanghai, September 7th 1889.

COFFEE TOPS.—It is cheering after hearing such poor accounts of some, and especially the higher, divisions of Uva in respect of autumn blossoms, to learn that on the lower estates, a proportion of blossom appeared and set, assuring a certain quantity of spring crop. We may be sure every attention will be given to bearing coffee in Ceylon this year and the utmost care taken to bring the crop to maturity. We trust also to see experiments made freely in cultivation after the fashion which, notwithstanding leaf-disease, borer and bug, has been found successful in Mysore. —In this connection we are much pleased to learn from Mr. Hamlin of his continued satisfaction with the large coffee clearing in Kondesale, Dumbara Valley: 140 acres have here been planted with fresh seed under the shade of *Ficus glomerata* (which sheds its leaves in the monsoon)—part is two years old and last year's clearing already requires topping. True on Kondesale the field has been interspersed with cacao in case the coffee should fail; but Mr. Hamlin has no doubt of the latter succeeding and will then probably open for coffee alone, using fresh seed and the *ficus* shade of course.

GUANO.—The *Times*, in its notice of the exhibits at the Jubilee meeting of the Royal Agricultural Society at Windsor has the following respecting artificial manures:—“Another large industry which has grown up during the last fifty years, is that of the artificial manure trades. It is not generally known that the present year is the jubilee year of the introduction of guano, the first crop having been landed in this country in 1839. The Anglo-Continental (late Ohlendorff’s) Guano Company have therefore prepared for the show an interesting exhibit, and also a pamphlet by Mr. Herman Voss, explaining and recording the history of its use for fifty years. Other noteworthy and instructive manure stands are those of Odams’ Manure Company, Messrs. Proctors & Ryland, and the Native Guano Company.”—*Sugar Cane*.

MINING IN CEYLON.—The letter of “Graphite” is a timely and useful contribution to the discussion in our columns which, we trust, is likely to result in a revolution in the present mode of conducting mining and gemming operations in Ceylon. He makes out a strong case for legislation and writes so much to the point that if the Government take no notice of the matter and do nothing, the next Coroner’s jury sitting on a man killed in a plumbago mine or pit, would be fully justified in adding a stronger “rider” to their verdict condemnatory of the Executive. The case is one indeed for an official inquiry and report as to the present condition and system of working for plumbago in Ceylon, and on such report, taken in conjunction with the legislative measures enacted in other Colonies, the needful ordinance could be drafted. “Graphite” opens up other and interesting topics in connection with the wasteful system of plumbago mining observed here; but we refrain from comment beyond saying that a fresh argument is thus adduced for the introduction of British capital to deal with the Ceylon plumbago, as well as gemming fields.

JAYAWARDANAPURA ARROWROOT.—The “Satvalokaya” of 16th Oct. contains an editorial note on the above subject. The editor says:—“That arrowroot is a very nourishing diet for invalids and the infirm, but what is sold in the market being adulterated with the starch of the sweet-potatoe, the cassava, and rice is not wholesome either for the sick or those in health. The arrowroot imported from foreign countries and sold in shops is too costly for the general public. Mr. R. P. Jayawardana of Cotta made an attempt to meet this want, and we are happy to see that he has succeeded in his attempt. The article prepared by him is quite pure and is of a superior quality. Though the price is 35 cents per pound it can be used without feeling any anxiety. It is always advantageous in the long run to buy a superior article at a high rate than one of inferior quality at a cheap rate; a sample of Mr. Jayawardana’s arrowroot was sent to Dr. J. D. Macdonald, M.D., the Medical Superintendent of the Colombo Hospital, who examined it and he has informed the Principal Civil Medical Officer and the Inspector-General of Hospitals that it is perfectly pure, and excellent in quality, and in his opinion a better article of diet than Brown & Polson’s corn flour which is sold at double the price, and that he has therefore given orders that this arrowroot be used in future in the Planters and Anthonisz Wards, and Seamen’s Wards of the Hospital to the exclusion of any other kind. The Editor of the *Observer* says in his paper that he has had a good report from a house-keeper who has tried Mr. Jayawardana’s arrowroot in several ways. She finds it much purer and whiter than which is bought at the door, and can recommend it as probably equal to and much less expensive than the West India arrowroot in tins. Moreover Mr. Jayawardana, has been awarded 2 silver medals at two exhibitions held in the island. He is preparing a sample of his article to be forwarded to the New Zealand and South Seas Exhibition, where, too, we hope he will carry a prize.

“PETROLEUM ENGINES.”—It is interesting to learn that two engines using kerosene oil are now in Ceylon and have been tried successfully: one on an estate upcountry for some time, and the other just proved satisfactorily in Colombo. We have been allowed to copy the following extract from a planter’s letter on the subject as of special public interest:—

“If you are to get an engine you should get one the same as ———’s petroleum. They are by far the best in every way and cost far less than any other driving power you can have, unless, of course, a water-wheel. They are as simple as an old pump and will go without anyone near them for any length of time, and if I had 1,000 acres of jungle near at hand I would get a petroleum engine. In fact there is no comparison, and I have seen ——— working for months now. They pour in the cheapest and coarsest kerosene oil into a tank, start the engine, lock the door of the engine-house, and it will go by itself the whole day. No fire or anything of the kind near it. It is just like a small cannon with the piston rod going inside it; and the power of force is obtained in the same way. Every time the piston crank revolves, there is an explosion of one drop of kerosene oil which of course drives back the piston rod, the oil is ignited inside the cannon breach by the electric spark, and you start and stop the engine by removing the zinc plate from the galvanic battery. There is no noise or sound and she works up to 8 H. P., but you can get them up to 350 H. P. I don’t know why our Company did not get them. Why a steam-engine costs ten times the amount to work.”

THE MAGAZINE
OF
THE SCHOOL OF AGRICULTURE,
COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for November:—

HOW DOES SCIENCE HELP AGRICULTURE?

V.

BY C. DRIEBERG, B.A., F.H.A.S.

Cattle are always associated with Agriculture in some way, whether for draught purposes or for milk and meat production. In Great Britain the use of cattle for the various agricultural operations has almost entirely died out—being now confined to a few districts in the southern counties of England. In Ceylon on the other hand cattle are exclusively employed for preparing the land and for any succeeding operations. Not only are cattle used for this purpose in agriculture, but nearly all the carriage in a country where the extent of railway is so small, and where horses are unsuitable for many reasons, is done by cattle.

How necessary then is a practical knowledge of Veterinary Science to those to whom cattle are so useful. Some of our landowners who own large areas of land at long distances from railway stations and towns are obliged to keep many head of cattle for cartage of the produce of their estates. The smaller landowners again keep cattle for milking purposes, while there are those who keep bulls for hiring out with carts and hackeries. The owners of grass-fields generally have a number of animals for the sake of the manure which they require for their land, for carting about the grass, as well as for milking. And yet if there is one thing more than another which has been neglected by the owners of stock, and allowed to be neglected by those in authority, it is the proper care of cattle. The careless manner in which cattle are exposed to the weather, the need of shelter and litter, as well as the insanitary state of the grounds where cattle are tethered, have brought about a condition of affairs which for other reasons

than the deterioration in the value of the animals and their produce, calls for authorized interference. If the owners of cattle knew anything of the dangers arising from this careless treatment of their stock, apart from the loss they incur by it, they would hardly continue acting in the same groove to which they have hitherto kept. Of late the subject of cattle disease has been ventilated to a great extent, and those who have read the information gathered, and opinions expressed on the subject, must by this be aware of the dangers with which the general public is threatened. In the matter of proper dieting with a view to the production of meat and milk and that of breeding, there is room for much improvement. What facilities have cattle owners had towards gaining the desired knowledge which Veterinary Science can give, or the aid which they might expect from higher sources? The fact is that there is no one who is authorized to come to their aid in special epidemic attacks which mean ruin for the smaller stock-owners; and there is no information being circulated for their benefit by anybody who is looking into this much-neglected matter—the improvements of cattle in Ceylon. The subject is one which presents a new field in so far as no one has looked into the matter from any but a purely remunerative point of view.

The importance that Veterinary Science has risen to in Great Britain and the Continent, especially in its relation to Agriculture, is no matter of surprise when we consider the dangers and losses which cattle-diseases bring about. "It was not till 1861," says Professor Wortley Axe, in an article on Veterinary Progress, "that notwithstanding that every nation in Europe had from time to time suffered enormous losses from bovine and other scourges, that any attempt was made to stem the tide of barbarism which had long flourished under the guise of farriery, and contributed so largely to the mortality of the live-stock of the world. Blacksmiths, grooms, shoemakers and horse-breakers were the oracles of the time. Armed with traditional rules and barbarous recipes, handed down from age to age, these miserable quacks vied with each other in the worst abuses of both drugs and knife. Bleeding, balling, blistering, and rowelling were practised with unmeasured ferocity. Every law of health and life were outraged under the pretence of medical knowledge, and the body tormented by a system which long survived the institution of our Veterinary schools." Professor Axe then goes on to contrast this state of things with the

present situation of the Veterinary profession whose relation with the medical profession is daily becoming closer: every year showing more plainly the necessity for co-operation between the two: while the British Parliament calls on members of the Veterinary profession for evidence in enquiries concerning public health. And what is the position of Veterinary Science in Ceylon? Why not a whit better than what it was in England in 1861: The traditional nostrums which Professor Axe so indignantly refers to are the sheet anchor of ignorant cattle owners, who blindly hand over fees to "miserable quacks" always ready to dupe them. I have seen enough of their vicious treatment during the recent epidemic! But how long is this state of things to last? While we are beautifying our parks and public gardens, are we going to allow disease and loss and misery to affect cattle and through them the people, and not move a finger in the matter?

It is a good sign that medical men have made a move, for often in a country that is passing through a stage such as ours is, it is thought necessary that some person "of high social standing" should foster a subject which till then is considered *infra dig.* to discuss, and make it *élegant*. Let us not despise the means, but let us have security at any cost.

Our cattle owners should know what precautions necessary in cases of epizootic attacks, they should adopt; and acquaint themselves with the rational remedies for ordinary ailments. They should be made to see that better shelter means less food for the beasts, and immunity from the many ills that originate with careless exposure: further they should better understand the subjects of food and feeding and their results in the production of more wholesome meat and more nutritious milk: while the sanitation of cattlepens should command their careful attention.

COTTON. IV.

By ABA.

In the early stages of its growth the cotton plant is of a very delicate nature and it becomes a matter of the greatest difficulty to suit it both in climate and soil, nevertheless localities do exist to a limited extent where both the climate and the soil are suitable. Keeping this in mind it becomes a matter of the greatest importance to the cotton planter to understand the peculiarities of the soil (leaving alone that of climate as beyond his control), to search out the deficiencies where they exist, and as far as practicable to remedy these by artificial means. It may not be possible to remedy all the imperfections, yet it is within the province of the planter by a judicious mode of cultivation to endeavour to meet the peculiar wants of the cotton plant.

Land on which cotton may be grown is found in various conditions, such as forest-land, chenas, ordinary garden land, &c., but I shall not stay to make any remarks about the preliminary operations required to be done in bringing any of these lands, under cultivation, as the operations of felling, clearing, &c., are known to every planter or cultivator. I shall only say that all lands, when practicable, should be thoroughly broken up with the plough long enough before planting to allow the atmosphere to act upon the soil. Experience in America has taught that ploughing is of the greatest importance in cotton growing. It has increased, it is said the lowland crops of cotton at least one-third.

I will now proceed to describe the mode of cultivating cotton which is followed on the Saidapet Experimental Farm where some of the happiest days of my life were passed. The land is first well ploughed; then harrowed, rolled, weeded, &c. It is afterwards thrown up in ridges of two feet apart. In the furrows between these ridges farmyard manure at the rate of 20 cart loads to the acre is applied. The ridges are now split through the centre with a plough, one-half being cast over the manure on either side, thus raising new ridges. These ridges are harrowed with the chain harrow to consolidate them, and Indian

corn and cotton sown along their tops. This is the best method of cultivation that is suitable on arable lands. The Indian corn would cover the cost of growing the crop &c. Instead of Indian corn some other "fine grain" crop may be sown between the rows of cotton.

Let us suppose that the intending cotton planter having selected his land has prepared it for sowing by ploughing or otherwise. The next thing to be looked to is the careful selection of the seed. The vitality of cotton seed is soon impaired; therefore the planter should be careful to procure fresh seed.

The planting should be done at the proper season; if indiscriminately done the drying of the pods might take place in wet weather and the cotton get damaged. It would be quite useless for the plants to grow well and the staple to get spoiled by wet weather. Bearing this fact in mind the planter should select a season for planting, so that the picking may come on in dry weather.

It has been ascertained by experiments recently carried on that the months of August and September are the best for cotton planting in Ceylon. In Southern India where the conditions are much the same as ours, planting is mostly done in these two months. The object aimed at in selecting these months for planting is to get the pods to ripen in January and February which are usually dry months with us.

I have already briefly noticed the different varieties of cotton, and will now give directions for planting each variety.

The Pernambuco or Kidney Cotton.—Two pounds of seed of this variety are sufficient for planting an acre. As the seeds are attached to each other, they should be separated previous to planting. The Kidney Cotton grows to a large size, and single trees are generally found growing in the compounds of native houses lasting for many years. Holes should be made at a distance of 4 to 6 feet apart each way according to richness of soil, in the prepared land, and two seeds put down in each hole. This variety of cotton it may be safely said is the best suited to the requirements of our climate and soil.

The Egyptian, although a perennial plant, is treated as an annual in cultivation. As this variety is not naturalized in Ceylon, it is well occasionally to procure first supplies of seed from outside as it tends to degenerate after several seasons of growth. Three pounds of seed are sufficient for an acre of ground, and the holes for planting should be made 3 feet apart each way.

American Cotton.—Of the American cottons the New Orleans variety should be preferred above all the others. It is especially suited for high cultivation, and where this is not followed it will not produce good results. As the plants resemble the Egyptian a good deal, the seed of this cotton should also be planted 3 x 3.

The Tinnevely is generally sown broadcast, but better results may be obtained by planting. The seeds should be put down closer as the plant does not grow so large as the other varieties of cotton. 2 x 3 feet apart would be about the best distance to make the holes. I have found it useful to steep the seed in a mixture of fresh cowdung and water before planting, as the plants are thus made more vigorous during the earlier stages.

PADDY CULTIVATION AND TRANSPLANTING.

IV.

By W. A. DE SILVA.

Irrigation.—Hitherto I have described briefly the process of selecting the seed paddy, raising it in the nursery and then planting out. But the principal requisite in paddy cultivation is irrigation, and this is a process which involves a good deal of time, labour and expenses.

It is generally admitted that paddy is a semi-aquatic plant, and it can grow to perfection only in the presence of water, and hence water is considered as the

principal requisite in the cultivation of this grain. The fact whether the aquatic character of the paddy plant is inherent in the species or is an acquired one is worth while being traced. In plants as well as in animals there are natural and acquired traits of character. Though they may have had other characteristics originally, a training up in a certain way with an object in view makes them acquire quite new characters which may be called artificial. When once through artificial or other means this character is obtained it is rather difficult to lead back a species into its original habits. To accomplish this the species should be allowed to degenerate, and this degeneration will not result in bringing the plant into its normal condition without permanently weakening it. So it is almost impossible to bring a plant which has been artificially or otherwise changed, to its original condition. We have these characteristics marked well in the cabbage tribe of the order Crucifere. The same species, *Brassica Oleracea*, has many varieties, each differing in its individual form; and the seed from each produces its own characteristic plants. This is an instance of a food plant, but the changes brought about by the Florist are still greater and strange. All these are done by cultivation; and "artificial" characters when once established remain tolerably fixed. Now coming to consider our paddy plant may we not infer that this aquatic character was given to it by artificial means; by cultivation to suit the condition of the cultivator?

But what causes could have made the paddy-plant of an aquatic nature? The original cultivator of paddy need not have had the special object of the cultivating in the paddy plant a taste for aquatic habits, yet other aims may have set him to work in a direction which favoured this result. May not a desire to loosen the soil, when there were no proper tillage implements (not even the native wooden plough) have prompted the use of a copious supply of water just before cultivation; again, may not, under the same circumstances, another object have been the destruction of weeds? Still further, keeping the plants erect and preventing them from falling down, and counting on a preventative in some degree of insect attacks in the absence of other and direct remedies. All these may have entered into the consideration of the agriculturist, and go to show the probable reasons why water was used in such large quantities by cultivators. The cultivators who were confined to the valleys of the large rivers had every facility for obtaining water in any quantity, which was no doubt fully availed of, but when the inhabitants spread and when they established new homes, they wanted their usual cereal as food, and it was cultivated in the same fashion as was done in the valleys. Where they could not obtain the copious supplies of water from natural sources they began to construct artificial reservoirs. Thus the tank system of irrigation might have come into existence, and the plant and the methods of cultivation became closely associated with water and continued and still continues so.

Other evidences are not wanting to trace back our paddy plant from the aquatic state to its normal state. We have the variety of paddy known as *Blai* or hill paddy, which is the same plant having the same characters as the aquatic one, but the only difference being in the conditions of growth. Hill paddy could be taken as a species having nearly its original characters, and passing from it we have a marked gradation in other varieties, some requiring less water and others still less. So this clearly shows that the character of the paddy plant as it exists now is an acquired one.

Anyhow, whether it be required or not, one thing is clear, that for the growth of the paddy as it is, water, to a more or less extent, is necessary. At the present day there is no regulation of this supply except when there is a limited quantity of water. Water is used abundantly when obtainable in every season. It is quite true that a certain quantity of water is required for paddy cultivation, and that quantity only for some definite purpose in the process of the cultivation of the crops; but at present this fact is not

understood, for when there is plenty it is used abundantly, and when there is little, sparingly. At one period of the growth of the crop the plants may have an abundance of water, whilst at another period they may suffer from a want of the same. But the supplying of fields with water in necessary quantity is quite possible. I have seen villages where, when the goyas get water, they fill up their fields simply for a desire of the thing, but otherwise when it is quite useless.

I shall consider here the different periods at, and conditions under, which water is required in the cultivation of a paddy crop both regarding quality and quantity; but it is a matter of regret that desirable facts cannot be given under these two important heads, as no careful experiments have been carried out in the matter, but which I hope will be undertaken very soon in the interest of the paddy cultivators.

According to the present system of working, the paddy cultivator before beginning his cultivation requires water for soaking the soil and destroying the weeds, making the field suitable to be planted with the native implement or puddled. This operation done—the water should be retained for some time, else the puddled field is likely to be baked and the soil hardened. So a necessity arises for the water to be left for at least another three weeks, or till the time for sowing. Though this process facilitates the cultivator in his operation, it is faulty in that the proper exposure of the soil to the atmospheric influence is prevented, and thereby the improvement which might otherwise arise is retarded. Thus when the organic matter in the soils decays away from the influence of the air, injurious organic acids are often formed; but no account of this and other circumstances are taken into consideration by our cultivators, who keep to the old and beaten track. In cases where dry cultivation is carried out which is a necessity when the supply of water is exhausted, the soil is exposed to atmospheric influences. This is the main idea kept in view in the improved method of cultivation. The land is ploughed and allowed to remain exposed till within a few days of being sown. The difference in the quantity of water required in the two systems of wet and dry cultivation is striking. In the former which is the common method adopted, the field is kept under water for a period of over three weeks before sowing to the great disadvantage of the formation of plant food in the soil itself; while in the other system which is adopted in cases of short supply of water, and where the system of cultivation with 'improved' implements is adopted, the field requires to be kept under water for a few days only just before sowing in order to prepare the seed-bed. In the case of transplanting a still greater reduction in the supply of irrigation water may be made, for the plants are put in after they have sprung up in a nursery and remained there for a month. The water which would otherwise be required during that month in addition to the three weeks' supply for soaking in the ordinary case of broadcast sowing would be saved. There would thus be a saving of a seven weeks' water-supply. This is rather a crude manner of estimation, but as the measurement of the quantities of water has yet to be made, the method I have adopted must answer my propose which is merely that of comparison.

The second period at which water is required is from a few days after sowing until the paddy is in flower. If we take for example a variety which grows 5 months, then water will be required till the beginning of the last month, as a month generally elapses between the time of flowering and the harvesting. Thus for an average crop of paddy which lasts 20 weeks, water should be supplied for a period, more or less, of 15 weeks. The first week and the last 4 weeks not to be taken into account, as very little is required at these stages of growth. When we add to this the 3 weeks before sowing, the time for soaking &c. of the field up to sowing time one get an aggregate of 18 weeks' water supply.

This amount is necessary in the ordinary method of cultivation. But in dry cultivation adopted either from a want of a proper supply of water or as the

results of the recognition of improved methods, the 15 weeks' supply during the growth of the crop is only required.

And lastly, in transplanting, a still less amount of water is required. For a five months' crop only 12 weeks' water supply is necessary, as no water is required for the month the plants are in the nursery. Therefore when four weeks are deducted the amount is reduced to 11 weeks' water supply, but adding a week for the little water required in the nursery the total will count to 12 weeks' supply.

The quantities of water required for the 3 systems will then stand as follows:—

18 weeks' supply for ordinary cultivation.

15 " " " dry " "

12 " " " transplanted paddy.

This shows that transplanting will require 33 per cent less water than is ordinarily required, and this saving is of no little importance in many districts where the supply of water is limited and where many fields depend on one source.

(To be continued.)

NOTES ON SOME OF THE GEOLOGICAL FORMATIONS IN CEYLON.

By C. DRIEBERG, B.A., F.H.A.S.

Sandstone belongs to that class of rocks which has had an aqueous origin. It is made up of small particles of sand, for the most part consisting of silica, agglutinated either by great pressure, by means of percolating acidulated water which dissolves and redeposits part of the materials composing the sand, by fusion, or lastly through the medium of some foreign substance in solution in water, commonly carbonate of lime, which acts as a cement. Often, however, the grains do not consist of pure silica, but particles of felspathic rocks, pieces of mica, and sometimes shelly débris are found mixed up in the mass. Again a large proportion of clay may be found in combination with the particles of sand. The texture of the rock varies greatly from the finest to the coarsest. This is often well seen in a deep cutting where the topmost layers may be very fine grained and gradually merge into coarse and coarser varieties. The commonest colours of sandstone are grey, white, and red, though the dark variety is not rare. The whiter varieties contain milky and clear quartz granules, the red colour of some sandstones being due to the presence of peroxide of iron, brown and yellow to the hydrous peroxide. The grey-blue colour of others are on exposure to the air, turned to brown or yellow, owing to the oxidation of the iron present.

Among the commoner varieties of sandstone are *freestone*, which is of a homogeneous character, and workable in any direction, being used much for building purposes: *flagstone*, more or less argillaceous and laid down in beds out of which they are worked and used for paving: *greensand*, which owes its colour to a mineral called glauconite; and *Carbonaceous sandstone*, containing organic matter, and generally of a dark or black colour. Where the agglutinated particles are tolerably large in size the sandstone passes into a *grit*; and the size increasing further still, the rock is characterised as a *conglomerate*.

Sandstone almost completely surrounds the Island along the coast, forming horizontal beds which are however much disturbed and fractured in certain places. The variety is not perfectly uniform, being sometimes of a light and again of a dark colour—the cementing medium being almost always carbonate of lime, which in the darker varieties is mixed with iron. The presence of carbonate of iron as the cementing medium is easily proved by heating a piece of sandstone rock with Hydrochloric acid when the rock breaks up and falls into a loose mass of sand.

The formation of sandstone as well as the limestones of the North must no doubt be explained by the theory which Mr. Nevill of the Ceylon Civil Service has endeavoured to prove in a paper written for the Ceylon Branch of the Royal Asiatic Society, viz., that the Islands subject to secular movement, that it is in fact

undergoing a process of gradual elevation. This is no wild hypothesis, as the phenomenon has been observed and the rate of elevation recorded in various places in Europe, notably on the coast of Norway. On the coast of Scotland the raised beaches extending in a series from 25 to 100 feet are a standing evidence of the fact, and such beaches are to be observed in our Island too, though they are not too apparent. The white sand of the cinnamon lands about Colombo are undoubtedly of aqueous origin, and of tolerably recent formation as evidences go to show. A peculiar bluish-black sand may be often observed on the sea-shore of our coast. This is composed of titaniferous iron (Ilurenite, an oxide of iron and titanium) and magnetite (ferroso-ferric oxide), the insoluble residue of igneous rocks. From Pamunngame, situated on the canal route between Colombo and Negombo is a bed of sandstone which is worked principally for the manufacture of filters.

AGRICULTURAL SUPERSTITIONS. III.

By E. T. HOOLE.

When we inquire into the origin of these superstitious practices and notions, we shall find that at first many of them were devoid of the superstitious character, and, as I said in concluding my last paper, were cunningly or even wisely invented. Take for instance the belief in blight by the 'evil eye' and 'evil tongue.' What a knowledge of human nature is here wrapped up! Of course there is no truth in the superstition as it obtains among the present generation of native farmers and gardeners. There is no 'evil eye' which can produce blight on well-growing crop by its mere look. I know however of the covetous eye and the envious eye,—the eyes of the man who contemplates stealing his neighbour's crops, and the eyes of him who cannot bear to see another's crop thriving, and therefore tries to injure it.

How attractive does a tree laden with ripe fruits appear to a light-fingered man! To allow him the chance of a sharp close look at the fruits would amount to tempting him to covet and steal them. But on the other hand it would wound the feelings of the man to let him know that the gardener has apprehensions about his honesty, and would not, for that reason, give him the chance of a visit to the orchard. As a cunning and easy alternative, therefore, in such cases ancient farmers and gardeners devised the superstitious notion about the 'evil eye' and gave publicity to it, so that it might have a common application.

The other class of evil-eyed men are the envious. When they get the opportunity of eyeing a very fruitful field or garden their envy is excited, and they try to do it some damage or other. The narration, in the Biblical parable, of the enemy sowing tares in his neighbour's wheat-field is not without its counterpart in the world of facts.

As a proof of the explanation I have here given about the origin of 'evil-eye' theory, I may point out that, even to this day, it is those who betray feelings of covetousness or envy upon looking at some good thing belonging to their fellow-creatures, that are especially marked down and dreaded as evil-eyed.

Then again the superstitious notion about the 'evil tongue' seems to have been invented in order to prevent an admirer rousing up the above feelings in bystanders. When a man expresses his admiration of some crop, he attracts the notice of others and makes it a mark for the rogue and the ill-willed man. The safest course would be to let the plants grow unnoticed and hidden from human view as much as possible.

Hence also has arisen the common custom of thatching garden fences with cadjans. A stick fence however strong is not considered sufficient; and the inevitable palm leaves have always come into requisition for covering the fence. While at Galle, I had an intelligent Jail Guard at the head of the gang of prisoners sent to the Experimental Garden; and he was somewhat imbued with the agricultural superstitions

of the land. This man was importunate in asking me to permit him to have the garden fence covered with olives, at least that part exposed to the human eye. At length I allowed it, more for the sake of satisfying him and keeping up his ardour and interest than for any other reason. When, however, the plants grew up and began to bear, I noticed that they were much safer thus covered round, than they would otherwise have been. The crops lay snug and secure unobserved by the evil-eyed, light-fingered gentry. It was hidden from the view of the four-footed rogues into the bargain, who otherwise would butt against the naked fence and try its strength when the growing crops tempted and attracted them with the prospect of something rich to feed upon. And I should think that the covering more or less, served as a screen from blighting winds and vermin and insects. What an amount of wisdom is thus wrapped up in this now superstitious practice, and how simple and effectual does it seem when it is all ascribed to the mysterious *aswaha* (blight or poison by the eye)!

We thus see that such practices were originally not superstitions but devices with some secret purpose in view, and that in process of time they assumed the superstitious character.

Take again the customs observed on the threshing-floor. What is their ultimate motive but to admit only a select number of honest good workmen and to prevent any chance of the corn being stolen?

The theory about the lucky hours seems to have been at first intended to enforce punctuality and prevent delay in beginning the different operations in so far as the farm-labourers, co-helpers, &c., were concerned.

There are other practices in which the motive is not quite clear. Yet they display good sense and reason when divested of the superstitious garb. For instance, in the Wann, the threshing out of paddy is delayed for about three months after reaping, the sheaves being in stack all the time. When asked the reason 'why,' the superstitious farmers say that they have to wait till the lapse of a certain festival which is celebrated in honour of a demon, and that otherwise the demon would reduce the quantity of grain by some mysterious means. But the desirability of the delay is apparent when the fact is noticed that the corn improves in quality when allowed to remain in the stack for a considerable time, by undergoing a certain change which is called "ripening in the stack." (Vide Tanner's Science of Agricultural Practice, pp 262 and 263.)

Again the belief that certain men's hands have a peculiar mysterious virtue in sowing, planting, &c., was intended as a sort of encouragement or flattery to cheer up expert farm laborers who were successful in their work, evidently because they did it well and were practised in it, and not on account of any special merit in them or their hands.

So it is clear that the origin of these superstitions show much wisdom. But what is to be deplored is the degeneration that these notions and practices have undergone. They have deteriorated to such a vile extent, that the notions are strained to the extreme and the original motives are lost sight of. The practices are observed indiscriminately without regard to time, place or other circumstances, and have thus assumed the gross superstitious character which characterize them now among the rustics of our land. And such degeneration of the ancient devices is now proving the bane of the native farmers. It has made their thinking powers dormant. Superstition narrows their minds and blinds their reason. They will persist in old notions and customs no matter whether they see their meanings or not; and spurn or dread any new practice. "Conservatism at any cost" seems their watchword.

There comes a good stranger who desires to have a look at *gamarala's* garden and is able and willing to give some useful information about growing the crops. But *gamarala's* belief in *aswaha* forms a bar against the admittance of well-meaning visitor to the garden.

Some improvement is suggested; but no, *gamarala* does not care for it. It is against ancestral custom. The superstitious mind is blindly conservative and does

not, and will not see any good in new methods and proposed improvements or reforms.

I apprehend that the resistance offered to the use of the Improved Ploughs is very much attributable to the evil effects directly or indirectly caused by superstition on the rural mind.

Superstitions then are no small impediments to the success of the young Agriculturists whom our *Alma Mater* has sent abroad to different parts of the Island to improve native agriculture. In my future instalments, I shall therefore, endeavour, to offer some words of advice to them as to how their work is to be pushed on in spite of such hindrances, and in what directions reforms are desirable.

Haputale, 16th October 1889.

INDIGENOUS FOOD PRODUCTS: CULTIVATED AND WILD.

CAPPARIDACEÆ.

3.—*Gynandropsis Pentaphylla*. D. C.—This is a herb growing in uncultivated places and also as a weed in gardens. It is known as *Waila* among the Sinhalese. It is an erect hairy annual and not very common, though it grows in uncultivated places. A peculiar pungent smell is found in the leaves, and a slight gummy secretion having the above characteristic smell is observed on the green surface of the leaves and the stem. The leaves are alternately situated, and divided into five partitions. The flower bunch consisting of small white flowers is a terminal raceme. The general colour of the flowers is milky white, and occasionally we have plants with a slightly pink-coloured flower. Another peculiarity in the flower is that the ovary is possessed of a stalk known as the gynophore. This plant bears pods and seeds resembling the mustard.

The plant is not of much importance as a food product, neither is it generally used; but my endeavour in these papers is to bring together as much as possible such species of plants which are more or less used as articles of food, and indicate the part or parts thus used.

In this plant the leaves are used for food. The leaves made into an ordinary curry form a good dish, having the characteristics of some of the cabbage tribe, but the pungent taste though not strong is very marked. It is also used fried in oil. In both these forms it possesses some important medicinal qualities. It is said that leaves of this used in food serve as an "excellent antiscorbutic and also an agreeable and invaluable medicine to seamen" possessing the qualities of *Cochlearia* and *Lepidium* of the European countries.

The seeds of this plant are similar to those of the mustard and possess an acrid oil which could easily be expressed. The plant is reputed to possess a good many medicinal properties and is a favourite one amongst native medical practitioners. It is used in cases of cobra bite and as a remedy in convulsions and Typhus fever. The several parts of the plant are used in cases of intestinal worms and in earache, headache and toothache frequently with success.

BIXINEÆ.

The indigenous plants of this natural order are few, and still fewer are any which are eatable. The two plants which I am going to describe below, are not much used as food, but still as the berries of both are eaten, I shall describe them here as wild products.

4.—*Phoberos Gaertneri*, Thw., or *Sclopiæ Gaertneri*, Mo n.—This is a plant growing wild and common in the warmer parts of the island. It is known as *Katu-kurundo*, among the Sinhalese. The plants are covered thickly with large-pointed spines which make them an effective barrier against the ravages of animals when used as fence sticks. The fruit is pulpy, and when ripe is of a dark red colour. It has a sweetish-sour taste, and is commonly eaten. The roots of this plant are said to possess medicinal properties and are used externally in skin diseases.

5. *Flacourtia Sapida*, Roxb.,—the *Uguessa* of the Sinhalese,—is common in the hot drier parts. The trunk and branches of this plant are covered thickly with spines, which are in most cases branched. It bears a round pulpy fruit which is of a dark red colour when ripe. This fruit is also of a sweetish sour taste, and is eaten when quite ripe. In an unripe state it is very astringent. The roots and bark form an astringent tonic and are used in cases of dysentery and fever to check purging and to relieve nausea.

OCCASIONAL NOTES.

REPORT ON THE CAWNPORE EXPERIMENTAL STATION.

The Cawnpore Farm which is under the superintendence of Mr. Meer Mohammed Hussain, M.R.A.C., who holds the post of Assistant Director of the Department of Land-Records and Agriculture of the North-Western provinces and Oude, was started in 1874. The account of experiments carried out on the Farm are of a diversified nature, and are relative to ploughing, irrigation, sowing, manuring and trials of different varieties of crops and seeds. The chief points aimed at by the experiments now conducted, was according to the report:—

(1) To estimate the value and utility of improved methods of farming compared with indigenous methods. (2) To form an idea, by weighing of crops, of the character of the season in point of outturn, and thereby obtain independent data for checking the agricultural forecasts of harvest yield obtained from the several districts of the province. (3) To produce pedigree seed for distribution in the country. The rainy season of 1888 was unfortunately most unfavourable to the carrying out of experiments, many of which resulted in total failure owing to successive wet; much of the seed having failed to germinate, and where it did germinate, the want of sun and heat injured the vitality of the plants. A great many of the crops experimented with are such as are not cultivated by our local agriculturists, and an account of the experiments with these would command no interest in our readers. In an experiment with regard to the comparative yield of different varieties of cotton the results were very disappointing; nearly the whole experiment being spoilt by the weather. Two points, however, seem to have been demonstrated: (1) that acclimatised is better than fresh imported seed, and (2) that a variety known as "Garro Hills" cotton resists wet seasons, giving the largest yield of all the varieties. The experiment in the comparative value of late and early sowings of cotton seed turned out a failure.

The superior value of gypsum or sulphate of lime as a manure for indigo seems to have been conclusively demonstrated.

The growth of indigo and hemp were found to prepare the land for cereals.

In the experiment to determine the effect of shallow and deep ploughing, or rather the effect of ploughing with the country and improved plough, the result was as on previous occasions in favour of deep ploughing.

The superior value of dead cotton seed as a manure was also clearly proved; and gypsum proved a valuable addition to dung as a manure for gram, peas and other leguminosæ.

The results of the irrigation experiments are unfortunately not noted: and as a whole the experiments seem to lack definiteness, but we have to take into account the difficulties under which Mr. Hussain was labouring, and must hope that his future experiments will not be interfered with by unlooked-for extraneous circumstances.

C. D.

A WORM REMOVED FROM THE EYE OF A HORSE.

In the year 1880 when I was attending an infirmary for cavalry horses in Madras as a pupil of Veterinary Surgeon Western of the Madras army, I had the good fortune to witness the successful removal by that gentleman of a living worm from the eye of a horse.

The animal was a dark bay Indian about 14 hands high, owned by Dr. Oppert of the Presidency College, and the parasite scientifically known as *filaria oculi equini*, I believe, was observed in the aqueous humour of the animal's left eye in a state of constant motion. The

poor animal seemed to be suffering from much nervous excitement and was visibly losing flesh.

Mr. Western began his operation by casting the horse on the right side and securely binding it so that it could not move. An ordinary lancet was taken, and some cotton twist wound round it exposing only a very little of the point, so that an incision into the coats of the eyeball may be made without the instrument penetrating too far. As the worm was in a constant state of motion, a point in the lower part of the eye where the *cornea* meets the sclerotic coat away from the direct line of vision was carefully watched and the guarded lancet thrust in when the worm reached this point. When the instrument was withdrawn the aqueous humour was squirted out and the parasite with it. The worm was about two inches long and looked very much like a bit of grey thread. It was very lively and lived till it was put in glycerine for preserving a few minutes after the operation.

As to how the worm got into the eye the Surgeon explained, if I remember right, that the *ovum* of the parasite was taken into the horse's system in the water which the animal drank.

After the operation the eye was wet bandaged to prevent inflammation, and the animal put into a dark stable. *Colchicum* was administered in half drachm doses. In about a fortnight's time the animal was sent away, the eye being perfectly cured with regard to appearance and strength of sight.

Since my return to Ceylon I had very little to do with horses, and I am not aware whether "worm in the eye" is recognised as a disease in horses here. I have come across a single instance only in which a thread-like worm was formed in the eye of an ox, but unlike the case of the horse the parasite was found outside the eyeball instead of in the aqueous humour.

"Worms in the eye" is a common thing in fowls. In an affected bird the eyes are swollen and a purulent discharge appears. Temporary blindness is brought on by the eyelids being held together by the sticky discharge. The fowl seems to suffer from great pain and refuses food. The most effectual remedy is lime juice. The eyes are forced open and a drop put in when about half a dozen or more thread-like worms fall off and the bird rapidly recovers. ABA.

The prize of R200 for the best essay on the cotton cultivation, offered by the *Ceylon Independent*, has been awarded to Mr. W. A. De Silva. The Judges were the Hon. J. J. Grinlinton, W. P. Holmes, Esq., and R. L. M. Brown, Esq. Mr. De Silva who quite lately published a pamphlet on cotton cultivation, passed out of the School of Agriculture in 1886. He was agricultural instructor at Minuwangoda, Andiambalam and Bandaragama, and was a few months ago appointed second assistant at the School of Agriculture. Mr. De Silva is also the author of a pamphlet, on "Coconut Cultivation" in Sinhalese.

CATTLE DISEASE AND REMEDIES.

Mr. H. W. Green truly says in his *Agricultural Primer* that "Natives when using medicines are too apt to trust to mere physicking, and so forget to feed the animal." In cases which I had an opportunity of watching lately, I found this to be the practice. The cattle were invariably given the ordinary food which they had no inclination to eat, and the owners simply allowed them to starve till they were told to administer rice gruel. Very often this starvation allows the animal to get into a state of weakness to which it succumbs. Not only is the feeding neglected, but no change is made in the housing of the sick animal, and no amount of advice can make cattle-men see the necessity of good shelter.

The animal should be kept warm and free from draughts, the roof should keep off the rain, while at the same time there must be ventilation. It is almost impossible to secure these conditions in the miserably sheds in which cattle are generally tethered.

With regard to medicines, Mr. Green gives the following prescription sent him by Mr. Saunders, which

he declares proved very useful in Ceylon "murrain".—A mixture of ginger, gall-nuts, bulu, nelli, catechu, kurumba-eti; 3 oz. of each grind fine, and dissolve in 1 pint of hotwater, add half a pint of arrack, and a quarter of a pint of margosa oil. In ordinary cases give one-third of the mixture thus obtained, twice a day. In very bad cases one-half may be given. Shake the bottle well before each dose.

I was informed by a Municipal Inspector who had visited a number of cattlepens, that a common practice among some cattle owners was to administer lard as a preventative, and that this proved very successful in keeping off the attack. Mr. Green in his Primer recommends 2 oz. of pig's lard for "hoof and mouth disease," and the late Mr. Worms of Ceylon, whose prescription for "rinderpest" was so highly thought of that it was even tried in England (where however it appears to have been a failure) includes $\frac{1}{4}$ to $\frac{1}{2}$ lb. of fresh unsueted lard in his recipe.

The action of lard is undoubtedly purgative, and it is evidently administered to keep the bowels in order. The following are the suggestions of Dr. Van Royen which a correspondent to the local *Examiner* reports were adopted with advantage in the Hill country:—

1. Segregate sick animals, keeping them well wrapped and secure from wind and rain.

2. Withdrawal of food, only rice congee or gruel, and gradually old paddy straw, but no grass till the animal is well.

3. As there is always congestion of the lungs and tympanitis (wind), have turpentine fomentations. A cumby is taken sprinkled with turpentine steeped in hot water, wrung out and wrapped round the barrel of the animal. This is repeated 3 or 4 times in the half hour. The fomentations should be repeated every 12 hours; oftener if there is distress in breathing.

4. An astringent should be given to check diarrhoea. Tincture catechu and tincture kino, of each 3 oz., 1 oz. laudanum and 3 oz. spiritus etheris, add water up to 2 pints and give $\frac{1}{4}$ every 4 hours. For calves half the dose. If breathing be quick a drachm of antimonial wine may be added to each dose of mixture; and if there be hemorrhage in the scourings, $1\frac{1}{2}$ oz. of liquid extract of ergot to each dose of mixture: but this is seldom required.

REPORTS FROM EXPERIMENTAL STATIONS.

RATNAPURA, 4th October, 1889.

Part of the Experimental Gardens in connection with the school at Marapana is laid down with a crop of American cotton. There are about three hundred grown up plants in a flourishing condition, the number of pods on each tree varying from 30 to 50. Considering the rainfall of last year, I think I might venture to say that little could be expected in the way of the successful growth of cotton at Ratnapura, at least the crop of lint cannot be expected to be of good quality.

My paddy field shows a superior growth to most of those round about. Four *haddes*—a quarter of an acre in extent, are being prepared for planting out paddy about next week.

I quite accidentally came upon a specimen of the *Indigofera tinctoria* growing in the garden of a native, just as I was about getting some seed down from Galle, where I had grown a crop. From this plant I gathered some seeds which I intend planting as soon as convenient. The question is, will it pay to cultivate indigo? If so, its cultivation will prove of inestimable benefit to the natives of the Ratnapura district where there is a considerable amount of available land suited for the crop.

WILLIAM KURUPPU,
Agricultural Instructor.

UDUWA, 5th October, 1889.

Uduwa is a pretty large village, containing over 150 dwellings, situated about 6 miles to the west of Bandaragama. The inhabitants depend chiefly on paddy and chena cultivation for a livelihood. The soil is very rich, and is generally of a clay-loamy

description. The paddy fields are very fertile and are irrigated by streams which run across them and fall into the Kaluganga. There is no doubt that the fertility of these fields depends in a great measure on the richness of the water in plant food carried down in solution and suspension from the neighbouring uplands. The paddy crop which is being now taken in, has not been damaged to any serious extent by the rains which we had during the latter part of last month, as has been the case in many parts of the district. Large stretches of land about here are under coconut and cinnamon. I have remarked some stray cotton plants growing exceedingly well, and consider it would be an admirable plan if the cultivators took to growing cotton in their chenas. I hope I shall before long be able to give cotton a trial. I have cleared, drained, and prepared in to plots, a small extent of land for the cultivation of vegetables; but at present I shall have to see to the transplanting of my paddy. I am glad to say that a number of the parents of the school-boys come and listen to my lessons on agriculture on Poya days and Saturdays.

D. E. TATHONIS,
Agricultural Instructor.

KEGALLA, 12th October, 1889.

The native goiyas, I am glad to say, show a marked change in their attitude towards the introduction of improved methods into paddy cultivation. I am, however, labouring under a disadvantage in having a very small extent of land, and one not well adapted for the purpose of an experimental garden. I am hoping that ere long I shall have some crown land not far from the new school bungalow at my disposal. It is only 5 months since I began my experiments here, during which time I have tried four varieties of cotton, tobacco, and some vegetables, all of which have turned out well. I have some arrowroot too coming up. I regret I could not have had some land under paddy, but I was unable to get either a suitable field, though the Ratamahatmaya tried to lease out one for me, nor the buffaloes. The R. M. takes a lively interest in agricultural work, and I am greatly indebted to him for much kind assistance he has rendered me.

J. W. P. SAMARASEKARA,
Agricultural Instructor.

WAYS AND MEANS.

Marking Farm Tools, &c.—Apply a thin coating of melted wax to that part of the tool where the initial letters &c. are to be engraved. Let the wax cool and mark the initials &c. on the wax cutting it completely through with a sharp nail or other pointed instrument. Now run a little nitric acid into the scratches, and after a few minutes wash the acid off and remove the wax by rubbing it off. The letters &c. will be found bitten into the tool by the action of the acid.

To Preserve the Natural Colours of Plants and Flowers.—Dissolve salicylic acid in alcohol, heat the solution up to the boiling point and draw the flowers &c. through it. Shake off any superfluous moisture and dry between sheets of blotting paper under pressure.

A Cheap Disinfectant.—Green Copperas or Sulphate of Iron, the *annabedi* of the bazaars, is a very cheap and effective disinfectant, and every Farmer can afford to use it in liberal measure. A pound to the gallon of water will deodorize and disinfect sewage &c. in a short time. It should be used in water-closets, in the kitchen, stables, and in fact everywhere on the farm all throughout the year.

To Remove Rusted Bolts, &c.—The most effectual means of removing bolts, screws, &c. that have rusted in, without breaking them is by the liberal application of kerosine oil. Care must be taken that the oil shall reach the rusted parts and some time must be allowed to give it a chance to penetrate and soften the layer of rust before the attempt to remove the bolt &c. is made.

GENERAL ITEMS.

Dr. Simpson, Health Officer of Calcutta, was here three weeks ago on his way to India from England. The post of Health Officer of Calcutta carries an immense salary with it. Dr. Simpson's supervision of slaughter-houses extends to one visit a month; he is endeavouring at present to bring about the appointment of a Veterinary inspector of slaughter-houses, as he is very strong on the point of a qualified man being appointed for the detection of unsound meat and looking into the subject of cattle-disease in India.

A CORRESPONDENT TO THE *Ceylon Observer* writes:—Mr. Aiyampillai, the additional Agricultural Instructor has come and taken charge of his work in Eraur, Batticaloa North. The adoption of the methods of transplanting paddy plants is now the earnest subject of controversy among many leading native landed proprietors, ever since they knew the success of that particular method tried at Nindiur, by the Agricultural Instructor, Mr. Ohelaliah. In regard to the merits of Mr. Green's Cingalee Howard's plough, the native land-owners, unlike two years ago, now readily admit the superiority of the new plough over theirs.

The practice of paring horses' feet, and especially the frog, by horse-shoers cannot be too strongly condemned, as the source of many diseases, such as navicular bone disease, deformed hoof, and pumice feet. The frog is a natural cushion for breaking the force of the shock to the bones. Farriers in Ceylon make a rule of cutting away at the frog, and owners of horses should give special injunctions to their horsekeepers to see that the frog is not touched.

£5,000,000 has been invested in Irrigation Works in California, and as a consequence the value of the land with water has increased from 10 to 50 fold. The taxable valuation has increased at the rate of £20,000,000 a year for the last four years. Under the influence of irrigation, counties which before were almost totally unproductive are now blooming with verdure and yielding abundant crops.

Mr. T. H. Middleton who distinguished himself so highly at the Edinburgh University in 1887-88, as well as in London at the Royal Agricultural Society's Examination, has been appointed Professor of Agriculture at Baroda.

Prof. Wallace has been entertained at a banquet got up by the Agricultural Society of New South Wales. The Prime Minister wrote expressing his regret at not being able to be present, but officialdom was otherwise well represented.

The Trade in Indian bones, conducted by Messrs. Arakie Brothers of Calcutta, has been risen from 200 tons in 1884 to 20,000 in 1889, and although their Calcutta Mills are now turning out 200 tons a day, they are unable to keep pace with the demand. They are consequently building even larger mills in Bombay to work the bone supply of Western India. There seems to be no doubt that there is a large future for this trade.

At a meeting of the South Durham Veterinary Medical Association last month, the President, speaking on the Infection of tuberculous meat and milk, said that to this might be traced one great cause of so many children dying from diarrhoea when a few weeks or months old. If an animal was suffering from tuberculosis it should be at once slaughtered. He was of opinion that animals suffering from tuberculosis should not be used as food, even if they were in a well-nourished condition. Private slaughter-houses should not be permitted, for he believed nine-tenths of the diseased meat offered for sale was slaughtered at these private slaughter-houses. "The Inspector of slaughter-houses should undoubtedly be a veterinary surgeon. Those only acquainted with what modern science taught were competent to pronounce between

sound and unsound flesh to be consumed as food. Even if we had any doubt about tubercularis being transmissible, which we have not, every means should be tried to stamp it out."

Three hundred and seventy-five cows are required for regimental food alone every day in India and 126,875 cows would be required for one year's food.

Guelph College Farm, Ontario, receives from the Provincial government a grant of £4,000 a year, besides the land extending to over 500 acres.

More than a million is disbursed by the government of Austria on the teaching of agriculture and the allied sciences. There are eighty-one schools of Agriculture and Forestry, of which six are State schools, and the remainder provincial, which are materially aided by State subventions. There are also agricultural winter schools for giving instruction during the winter when work is slack. Agricultural libraries to the number of 887 have been established and supplied with 58,000 volumes either directly by the Ministry of Agriculture, or by it in conjunction with provincial and local societies. A considerable contribution has also been made towards travelling lecturers who deliver lectures on general agricultural subjects.

The quantity of unsound meat seized at the slaughter-house, Edinburgh, during the month of January last year, amounted to 13,476 lbs. made up of 12,808 lbs. of beef, 236 lbs. of mutton, and 432 lbs. of veal. Seventeen carcasses of beef were condemned for tubercularis.

Mr. R. P. Jayewardene of Kotté has been awarded a medal for his "Jayawardhana Pura" arrowroot, which he is now introducing into the market. The article has been favourably reported upon by the Government analyst, to whom samples were submitted for analysis, and we are glad to hear that it is now used in the wards of the General Hospital at Borella to the exclusion of all other preparations.

At a trial of the Strawsonizer at the Paris Exhibition, the judges declared the new invention a complete success.

RAINFALL FOR AUGUST.—In Colombo only 4.66 inches of rain fell during the month, the greatest quantity in any twenty-four hours being 1.05 on the 22nd and 23rd. The largest quantity of rain registered anywhere in the Island for the month was 31.20 inches at Theberton Estate, Maskeliya, 5.50 inches falling in 24 hours on July 31st and August 1st.

SCHOOL NEWS.

The practical work of the school during the past month consisted to a great extent in the preparation of land, from which the dholl crop was recently removed for Indian corn. The evening work is confined to the vegetable gardens, which in spite of the careful drainage of the land, were on more than one occasion under water, and consequently suffered somewhat. The kidney cotton trees in one plot have been pruned after the gathering of one crop, and give promise of another good yield; while the young cotton plants are coming up well. A few mornings about the middle of the month were devoted to the preparation of the paddy fields at the back of the school, and the transplanting of the paddy.

The Veterinary class as well as the other students were present at a post-mortem examination of a bull that died of the disease at present prevailing in and around Colombo.

Mr. J. S. De Saram still continues to act as District Judge of Tangalla, Mr. Rodrigo, of the Bentota Training School, doing his duties.

The school eleven played two matches during October. In one against the Garrison they were beaten by 3 wickets; in that against the Sinhalese Cricket Club the latter were beaten by 8 wickets.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. IX.]

COLOMBO, DECEMBER 1ST, 1889.

[No. 6:

THE VEGETABLE IVORY PLANT.

correspondent has sent us a leaf from a periodical called "The Family Doctor," containing an interesting account of the palm, the seeds of which are used as a substitute for ivory. A pretty engraving of this procumbent-stemmed and feathery-leaved palm is given, with the description which we quote, but we have had to seek elsewhere for the scientific name. It is *Phytelephas macrocarpa*, one of the most beautiful as well as curious of the palm tribe, of which the magnificent talipot is the undoubted monarch. The leaves of the so-called ivory palm rise, like gigantic ostrich feathers, to a height of sometimes 40 feet. The fruits, or rather fruit depositaries, are as large as a man's head, and contain numerous nuts which when ripe, closely resemble ivory in whiteness and hardness. The leaves are used by the Indians for thatch. As the habitat of the plant is the northern part of South America, we see no reason why this plant should not succeed in the plains and along the river sides of Ceylon. We recommend it to Dr. Trimen's notice, if he has not already introduced it or made the attempt. Tea planters in the low-country might well try it, for ornament if not for commercial utility. Some botanists are inclined to separate this plant from the palms and erect it into a separate natural order. In its anomalous position and in its uses, it so closely resembles the *Nipa* palm (so-called) that we were strongly reminded when reading the article quoted of the *Gin-pol* of the Sinhalese,—the "water coconut" of the English. It resembles the coconut palm, however, only in its foliage, the fruit closely resembling that of the ivory palm. But that it has a creeping stem, the classification of the *nipa* with the *pandanus* or screw-pine plants would seem

to be justified, for, like them, it grows specially in brackish water. But it differs so much from the Palms and *Pandanaeæ*, that it, like the ivory palm, is placed by itself as the only species of a genus. In Java the "nipa palm" is of great economical value, the bamboo houses (rendered necessary by the prevalence of earthquakes) being covered with thatch made of the long nipa leaves. Ready plaited they are to be constantly seen carried about for sale. We are not aware that the leaves, about 20 feet long are ever so utilized in Ceylon. When burnt they are said to yield salt. From the spadix, toddy with the same qualities as that obtained from the coconut is extracted, and the seeds are edible. We can recollect our disappointment when, very many years ago, we gathered some of the curious screw-pine-like fruits, to find that on parting with their moisture they fell to pieces. Those interested can find specimens growing, *in the water*, on the edges of the backwaters or "gobbs" which commencing south of Colombo are prominent as "lakes" at Moratuwa, Panadure, &c. And no doubt the *gin-pol* grows on the shores of the Negombo Lake. Geologists have found that a similar plant abounded, in the tertiary period, in the waters of the Thames. We are not aware that any economic use is here made of the leaves of the curious "screw-pines," which are so numerous standing out of the water on their stilt-like aerial roots in backwaters and swamps. The fruits of the *Pandanus* are eaten by the aboriginals of Australia, and there is one valuable species, the *Vacoua*, which is converted in Mauritius into sugar bags, those bags being subsequently used in Britain to form the fish bags, commonly used in the markets.

We submit that the "ivory" palm should be added to the long list of South American plants already naturalized in Ceylon, and that our own "water-coconut" and screw-pines might be utilized more than they now are. Fibre from the latter,—stem as well as leaf fibre might be useful at any rate as a paper material.

(From the "Family Doctor.")

THE IVORY PLANT.

So different are the products of the animal from those of the vegetable kingdom that even the most careless observer may be expected to distinguish them. Yet multitudes are in the daily use of ivory buttons, boxes, and small ornaments who never doubt that they are made from the tusks of the elephant, while they are really the product of a plant. The ivory plant is a native of the northern regions of South America, extending northward just across the isthmus of Panama; large groves of it have been recently discovered in the province of that name.

It is found in extensive groves—in which it banishes all other vegetation from the soil it has taken possession of—or scattered among the large trees of the virgin forests. It has the appearance of a stemless palm, and consists of a graceful crown of leaves, twenty feet long, of a delicate pale green colour, and divided like the plume of a feather into from thirty to fifty pairs of long, narrow leaflets. It is not however, really stemless, but the weight of the foliage and the fruit is too much for the comparatively slender trunk, and consequently pulls it down to the ground, where it is seen like a large exposed root, stretching for a length of nearly twenty feet in the old plants. The long leaves are employed by Indians to cover the roofs of their cottages.

Each flower of the ivory plant does not contain stamens and pistils, as in most of the British plants, but, like our willows, one tree produces only staminal flowers, while another has only pistillate ones. Such plants are said by botanists to be diœcous. Both kinds of the plants of the vegetable ivory have the same general appearance, and differ only in the form and arrangement of the flowers. In the one kind an innumerable quantity of staminal flowers is borne on a cylindrical fleshy axis four feet long, while in the other a few pistillate flowers spring from the ends of the flower stalk. Each plant bears several heads of flowers.

Purdie, who visited the plants in their native locality in 1846, says: "The fragrance of the flower is most powerful and delicious beyond that of any other plant, and so diffusive that the air for many yards around was alive with myriads of annoying insects, which first attracted my notice. I had afterwards to carry the flowers in my hands for twelve miles, and though I killed a number of insects that followed me, the next day a great many still hovered about them which had come along with us from the wood where the plant grew. The group of pistillate flowers produce a roundish fruit from eight to twelve inches in diameter, and weighing when ripe about twenty-five pounds. It is covered by a hard woody coat everywhere embossed with conical angular tubercles, and is composed of six or seven portions, each containing from six to nine seeds. Those seeds when ripe are pure white, free from veins, dots, or vessels of any kind, presenting a perfect uniformity of texture surpassing the finest animal ivory; and its substance is throughout so hard that the slightest streaks from the turning lathe are observable. Indeed, it looks much more like an animal than a vegetable product; but a close comparison will enable one to distinguish it from the ivory of the elephant by its brightness and its fatty appearance, but chiefly by its minute cellular structure. This curious hard material is the store of food laid up by the plant for the nourishment of the embryo, or young plant contained in the seed. It corresponds to the white of an egg of the hen, and has been consequently called the albumen of the seed. In its early condition the ivory exists as a clear, insipid fluid, with which travellers allay their thirst. Afterwards the liquor becomes sweet and milky, and in this state it is greedily devoured by bears, hogs and turkeys. It then gradually becomes hard. It is very curious that this hard mass again returns to its former soft state in the process of germination.

"The young plant for some time is dependent upon it for its food, and if the seed be taken out of the ground after the plant has appeared it will be found to be

filled with a substance half pulp and half milk, on which the plant lives until it is old enough to obtain its food on its own account. From the small size of the seed the largest not being more than two inches across its greatest diameter, the vegetable ivory can be employed in the manufacture of only small articles, such as beads, buttons, toys, &c. What is wanting in size is, however, often made up by the skill and ingenuity of the workmen, who join together several pieces so as to make a long object, when it is easy to hide the joints from view, or make a lid from one seed, and the box from another."

We do not know if a specimen of this plant has ever reached this country, or whether vegetable ivory is a product made use of by the British cabinet maker, but we cannot for a moment be in doubt as to the beauty of the material in question—albeit, the smallness of the seed is much against its being generally used.

COFFEE PLANTING IN JAMAICA.

The following extract from the letter of a planter, dated Oct. 25th, 1888, got mislaid, but is still worth printing:—

Crops this end of the island (Carpenter's Mountain Range) are very poor, owing to the long drought from November 1887 to April 1888. I have an idea that a drought of moderate length would always do us good but it doesn't suit this district of the island, to have a dry March, the April and May blossoms in dry years give us all our crops; but later blossoms, June and even July (a universally late one) are no good as we have to strip the trees about the end of January or early in February. This year we have had an extraordinary spring on the trees: my bearing fields have made more wood than I have ever seen, and it is hard to believe they gave such good crops for the last four years as they have given, viz., 80 tierces 55 tierces 53 tierces and 74 tierces each 850 lb. nett, but this year comes a drop, I don't expect more than 25 tierces but have great hopes of the "Planter's Year" (*i.e.*, next.)

I think I told you some time since that our method of establishing a field is to give out the woodland to the natives free of rent for three years, binding them to cut down, burn and clean up and get ready for lining and pegging; then after the pegging is done they are at liberty to plant certain provisions between the pegs, and after the planting they are to keep the young plants free from weeds in consideration of their getting the land rent free. The land is generally cut down and burned up in March and the pegging done immediately. I never plant till September as I find there is a much better chance for the plants to be established during the cool winter months, than if planted in April and May, as very often after the May rains are over, the hot sun of July, August and part of September is enough to burn the plants out of the ground.

I have now planted just over one hundred acres in three years, and am glad to say the first planting nearly 60 acres is looking in excellent order, and this year gave me a small picking (two years old) and next crop I expect a fair picking. When my new plants are all in bearing I shall have three hundred acres of bearing coffee; but in the meantime I am still going on with the planting as I "have my doubts" as to the increase of coffee production in Brazil, now they have emancipated the slaves.

You will never get West Indians to believe that emancipation increases production: it is a lovely theory and should for the sake of the Exeter Hall party prove the case; but "our friend and brother" isn't ambitious, he doesn't care to provide for a rainy day, he has no wants that a shilling or two cannot obtain, and after the effort of labor to obtain the necessary shilling or two he lapses into the condition of the "honest British labourer," *i.e.*, "he 'ates work and 'ates them as likes it" till his desire for some other luxury (in the West Indies no native works or has need to work for bare necessities) causes him to turn out. I give you an example of the typical Jamaica

negro. In the coffee districts, proprietor asks a man with large family, and who owns a settlement bordering on his property, why he never works for him, and mentioned that for years he had never seen either himself or any of his family on the payroll. "Well, sir," says the man, "I make about 500 lb. coffee every year, and I don't mean rudeness massa, but, I would see any one d—d before I would work while the coffee money lasts"; (his expression was till he had ate out his coffee) and this is the sort of gentlemen we were told would make the railway pay on account of the enormous extra cultivation that would ensue when the facility for carriage was made evident!

TEA NOTES.

CHITTAGONG, Oct. 3rd.—Chittagong has had a fair quantity of showers and the weather is now clear and hot.

SOOTEA, Oct. 6th.—Clear hot days with cold nights. No rain since the 28th ultimo, and the gorgeous sunsets, which usually occur during the early months of our cold weather, have already begun. Outturn appears to be falling off seriously everywhere. The cold nights have the effect of making the leaf leathery, and the manufactured tea has already taken the Autumn appearance and flavour. In fact everything points to the early close of the most dismal rains I have yet seen in Assam. Polo and snipe are in.

DEHRA DUN, Oct. 8th.—We are still making tea but the cold nights are stunting the flushes. A little rain would be welcome.

A meeting of representative planters from each district in Assam is to be held on the 29th of this month, when it will be proposed to form a local Tea Association with a paid Secretary to work in conjunction with the present Indian Tea Association.

The General Committee of the Indian Tea Association have resolved to support a scheme proposed by the Agri-Horticultural Society for the analysis of the Tea Plant, soils, and the various manures practically available, and also for scientific enquiry into the chemical changes undergone by Tea Leaf in the process of manufacture: the expenditure involved in the employment of an expert &c., will amount to £10,000, which is expected to cover experiments and investigation over a period of two years.

The General Coolie Recruiting Association is, we hear, daily receiving accession to its numbers both of the trading Agents in Calcutta and of planters in Assam, among the latter we may say the scheme is universally approved of.—*Indian Planters' Gazette.*

PLANTING IN JOHORE.

(From the *Singapore Free Press*, Oct. 16th.)

I am trying a new departure in labour. A month or so ago Mr. Bentley asked me if I would take on some Kelantan coolies, as an experiment. They were to get \$4 per month for the first two months, being only raw hands, and then rise to \$5 per month; but a stipulation was made that they were not to rise above \$5. This is a move in the right direction. At present our cheapest labour is Javanese at \$5.50 a month; and this is a long figure when compared with other countries, India and Ceylon for instance, especially when the cost of living is considered. Two dollars a month supplies them with rice. They grow their own vegetables and catch their own fish. This leaves them \$3.50 monthly for clothes, gloves and cigars! or if not extravagant in these items, they can lay by pretty well the whole of this sum. I wish my income would quarter out in like proportions!

So far the Kelantans are a success, working steadily and regularly. They are a merry lot; and the other day when one of their number running down-hill with an empty wheel-barrow, tripped and turned a somersault over his barrow, which landed on the top of him, their laughter was loud and long. The man who came the purser seemed to enjoy it as much as any of them. I had no idea what unsophisticated savages they were until I got them into the store one day to carry some boxes. When they saw me stencilling the boxes their

astonishment was profound; when I proceeded to weigh the boxes on a Fairbanks' scale, it was still more so, but the climax was reached when the clock struck! They crowded round it, and when it had done striking one after another went up to it and put his ear against it listening with staring eyes and gaping mouth to the mysterious tick inside!

Mr. Bentley, Protector of Immigrants and Dr. Wilson recently made an official trip to Batu Pahat, and came back with grand accounts of the coffee there. The Doctor managed to secure a plant of the Kola nut: "What's that?" I asked. "The drunkard's friend" replied the Doctor with a twinkle in his eye. So there! some hope for Singapore yet!

TEA PLANTING IN ASSAM: SHORT CROPS.

(By an *ex-Ceylon Planter.*)

Oct. 16th.

This has been one of the wettest seasons ever known in Assam. Such an abnormally cold and wet season has not been conducive to large yields, and the outturn will probably be considerably under that of last year. Red spider, green fly and mosquito blights have each in their turn retarded flushes, but although the outturn may be a little short in some cases, this will be made up for by the satisfactory prices we are getting.—In comparing Ceylon with India I notice that you predict that Ceylon will be able to produce its teas cheaper than India and that many gardens in Assam will be unable to carry on and produce tea at a paying rate. In this I think you make a mistake. Your planters vie with each other in trying to show how cheaply they can turn out their teas. Assam planters have not yet felt the necessity for that, but when the time comes to curtail expenditure I believe we can do it. Our teas per lb. are costing less now than formerly, not because we have reduced expenditure, but because we have been spending more and making more tea. What we want to do now before Ceylon shuts us up is, to improve our system of working so that we may be able to reduce expenditure without reducing the yield.

The publicity given to everything connected with the tea industry and the unanimity among the planters themselves give Ceylon men a great advantage over their brother planters in India. We here are so obstinately conservative that there is no such thing as unanimity. Gardens are far apart for one thing, and one never hears what is going on in a neighbouring district. Even in one's own district we know little of what is going on. This may appear strange, but is nevertheless true. In my own district there are gardens within easy distance which I have never seen. It's not the custom, and you only raise the ire of the manager if you propose to have a look round his garden and try and pick up wrinkles. This state of things will no doubt improve in time. A move is now being made to reduce the cost of importing coolies, and a very substantial reduction is expected to be effected. At present it does not amount to more than your head money, and the average daily wage is half what yours is.

CEYLON TEA IN AMERICA.

Every indication of our teas making way across the Atlantic in public estimation is of special interest. We have been favoured with a sight of that most popular of American periodicals (for children), *St. Nicholas* for last month (Oct.), which opens with four pages of "Interesting Facts about Tea"—manifestly an advertisement, but so well printed and placed, as to have all the attractiveness of a Magazine article. The credit of its insertion is due to Messrs. Joseph Tetley & Co. of London and New York, and certainly there is very plain speaking for the benefit of American housekeepers and tea drinkers generally.

We quote as follows:—

Be it known in the first place, that the China and Japan teas have an almost absolute control of the markets of this country, for the reason that the large importers and dealers have been able to secure a better profit on these than on the finer and more highly cultivated teas of India and Ceylon. England, Ireland, and Scotland are unquestionably the leading tea-consuming countries of the world; therefore it may be justly claimed that the cultivated taste of the British tea-drinker can be taken as a standard. The large amount of "English Breakfast Tea" being sold in the United States does not bear the faintest resemblance to the tea which is generally in consumption in Great Britain. The teas which have swept all before them in Great Britain, viz. the growths of India and Ceylon, are practically unknown here, as out of an annual consumption of about 88,000,000 in the United States only about quarter of a million pounds comes from India and Ceylon. During the last fifteen years there has been a revolution in the tea trade in Great Britain. In this short time the consumption of Indian and Ceylon tea has risen from 18,000,000 pounds per annum to 118,000,000 pounds per annum; while the annual consumption of all other teas, including those from China and Japan, has fallen from 118,000,000 pounds to about 62,000,000. This absolutely proves that in the judgment of the people of Great Britain the teas produced by India and Ceylon possess qualities which lift them far above all others. They have greater strength which makes them more economical, as the same weight of Indian and Ceylon tea goes much farther than that of any other growth. They also possess in the highest degree all those qualities which combine to make a delicious and invigorating beverage, viz. flavor, fragrance, and bouquet. Two attempts have been made to introduce these teas to the United States. A syndicate of Indian and Ceylon planters shipped two consignments of their teas to New York, which they determined to have sold in public sale without reserve, in the hope that they would filter through into consumption and so create a demand for their products. These attempts were frustrated by the formation of a ring, which bought the teas at its own price and reshipped them to the London market, showing clearly that they feared the enormous profits they were making on the inferior goods from China and Japan would receive a serious blow if the finer and more highly cultivated teas of India and Ceylon were introduced into this country. Then as regards China teas we are told:—

Mr. Samuel Ball has conclusively shown that throughout the whole tea districts of China innumerable other leaves are constantly employed as substitutes for the genuine leaf, while a long list of plants is to be found in many Chinese herbals to which the term "tea" is applied without any regard to the fact that none of them are tea at all. All, however, are used at various times and in different places to swell the crop of genuine tea, and the result is, as was testified recently before the House of Commons, millions of pounds of sloe, liquorice, ash, and willow leaves, are every year imported into England from China under the name of tea. Used leaves again are often made up for the English market with Prussian blue, silica, gypsum, plumbago, lamp-black, ferruginous earth, and other palatable trifles; and a recent analysis of "Finest Kaisow" and "Fine Congou" revealed in the former an enormous admixture of mineral matter, mostly iron filings, and in the latter redried tea leaves, straw, fragments of matting, rice husks, willow leaves, and the excrement of silk worms. In some "Extra Fine Gunpowder" Dr. Lethby, then Government analyst, found 40 per cent. of iron filings and 19 per cent. of silica, while the commissioners of the city of London have more than once made extensive raids on huge consignments of adulterated and artificially colored Chinese teas. To come still further down, on the day before the last mail left Europe the police of Dunkirk acted on information from the Municipal Laboratory, arrested two grocers of that town on the charge of having, for several months, sold large quantities of dyed leaves under the name of tea. Both the trade men were able to show that they had been supplied

by a wholesale firm in Paris. Samples were accordingly bought from the firm by order of the Parquet and were sent to M. Riche, a chemist. His report showed that the leaves submitted to him were not tea leaves. They were like, most dried leaves, of a brownish color, but this was hidden under a thin coating of a bluish green substance, which easily rubbed off. Their appearance was exactly that of gunpowder tea. Unlike the celebrated nutmegs, it has been impossible to tell to what plant they belong, the leaves having been punched out of larger ones. The wholesale merchant denied any knowledge of the fraud, and referred the authorities to the importer, who, it transpired had bought the concoction direct from Canton. The inquiry into this cheerful business is still in progress.

With the Indian planter the whole system is different, and not only is the utmost care taken not to grow or ship inferior leaf, but every pound exported is absolutely pure. From the plantation to the ship the tea is practically under the care of one man. There is no passing it on from hand to hand, no tinkering with it, and no holding of small stocks (which are deteriorating every hour) until there is a large enough accumulation to dispose of to a shipper. The tea is rolled, dried, and shipped in the shortest possible time, and is a subject of anxious care to the planter from the moment of planting to the very hour of sale. As a plant, the Indian tree is infinitely superior to the Chinese. India, indeed, is the real home of the tea plant, which, there seems little doubt, was introduced from India into China by Dharma in the year 510. The system of cultivation is superior, the manufactured article is pure and has no artificial coloring; its intrinsic value is greater, its health-giving properties are far ahead of those of its rival, and without it as a "fortifier" an enormous proportion of the present imports of China tea would be absolutely unsaleable.

Such advertising, followed by full particulars as to prices, quantity to use, &c., cannot fail to do good in bringing Indian and Ceylon teas more and more into notice and use.

COFFEE: A CHAT WITH A MYSORE COFFEE PLANTER.

"I presume that very few of those who are fond of a cup of good coffee for breakfast in this country have anything like a clear idea of the agricultural processes which render such indulgence possible," remarked George Anderson, of Mysore, India, an elderly gentleman, with silvery mutton-chop whiskers, keen gray eyes, and the tawny sallow complexion which seems to be inseparable from the resident of the land of torrid suns and diseased livers, as he smoked an after dinner cheroot in the lobby of the Russell House yesterday afternoon. "I know all about it from a long series of years of actual experience in coffee raising," he continued, "and nothing could afford me more pleasure than to enlighten the readers of the *Detroit Free Press*—a paper which is more widely read in India than perhaps any other paper in the world, except the *London Times*—upon the subject I have been a resident of Mysore, India, for an unbroken period of twenty-seven years. I went out to that country as a very young man when the possibilities of civilization were all before it. I have never had reason to regret doing so. If you are familiar with the geography of India, you are aware that Mysore is blessed with a delightful climate, something which cannot truthfully be said of many other portions of that great and rapidly progressing country. I experienced hotter weather in Salt Lake City, since coming to this country a few weeks ago, than I have ever known in Mysore during the entire period of my residence."

"Are you a coffee planter?" was inquired.

"That has been my business for many years," Mr. Anderson, igniting some sort of a long, lanky looking roll of tobacco, which bore unmistakable evidence of heathen birth. "I will endeavour briefly to give you some sort of an idea of what it means to be a coffee planter in India. In the first place you must understand that the refreshing rains which water the vegetation of this country every few days are unknown in India for months together. Drought is the great enemy with which all agriculturists are forced to contend. This atmospheric condition is the greatest obstacle with which we have to battle, and it has made India the most prolific country in the world in the matter of inventing and perfecting all sorts of irrigating processes. In that one particular, at least, we easily lead all other civilized countries today. Coffee plants or trees, as they may very properly be termed are planted five feet apart, in each direction. Everything has to be done by hand. There is no such thing as labour-saving machinery known in connection with the business. Its use would be impossible. The tops of the coffee shrubs are cut out to force them to shoot out horizontally, instead of into the air. But the coffee bushes on a plantation are not the only adjunct of the business which requires cultivation. On account of the drought and the torrid sun, every inch of the plantation must be fully protected by shade trees. Where this is not done the fruit shrivels up and becomes worthless without ripening. Experience has taught us in India that the only really desirable trees for shade purposes are the silver leaved variety. The rays of the sun seem to penetrate all others and the labour of cultivating them is wasted. We generally shade our coffee plantation with part or all of the eighteen or twenty varieties of fig trees indigenous to the country. Where these trees are not properly located, they must be planted and cultivated. No branches are allowed within twenty-five or thirty feet of the ground, and annual trimming and pruning of both the coffee trees and the big trees which shade them are absolutely necessary. You can doubtless form some idea of the immense amount of labour which this process entails. There is no more beautiful sight, however, than a properly cared for coffee plantation after it has reached maturity. The green bushes in regular rows below and the equally green trees towering above them with protecting arms form a very pretty picture. In May the coffee bushes are in full bloom, the white blossoms, something after the mignonette order, causing the perspective to resemble a waving, palpitating field of virgin snow. The picking of the berries begins in November and continues until February. As I have said, all labour is done by hand, and I regularly employ about 600 coolies in managing my plantation. The picking process is naturally a tedious one, but labour is heap in India. If such were not the case, coffee would be a luxury which few would be able to afford."

"What does the coffee berry resemble before it is plucked from the bushes?" was asked.

Mr. Anderson smiled.

"I fear you would have some difficulty in recognizing it at that stage of the proceedings," he replied. "In colour it is a brilliant red looking very much like a large ripe cherry. The berries of which the beverage is made are, in reality, the stone of the fruit. The pulpy substance by which they are surrounded is sweet in taste, but has never been utilized for any purpose. At one time a sort of liquor was manufactured from it, but it failed to win its way into public favour. After tasting it

you would not be surprised that such was the case. Two coffee berries are contained in each of these cherries, or fruit bulbs. After being plucked from the bushes, the fruit is placed in vats, and a process of fermentation takes place which separates the pulp from the berry. The latter is then subjected to more mechanical devices, which removes the remaining film. When the product reaches the coast, a sort of scouring process is undergone which places it in condition for market—a condition with which you are familiar."

"What is the average yield of a coffee bush?"

"One pound of the prepared berry is a very fair average per bush. The yield more often falls under that figure than goes above it."

"Do you export your own product?"

"Entirely. I have no dealings with middle men. After a quarter of a century of experience, I pronounce that as by all odds the most profitable plan to pursue."

"Is the society of Mysore desirable?"

"The best in the world," was the emphatic reply. "India escapes the adverse social influences with which most countries are afflicted. Only men with an honest desire to get on in the world come to that country. It is no place for unprincipled adventurers. There is nothing for them to prey upon. Bangalore, my nearest large city upon the coast, is well advanced in everything which renders a city great."

Robert P. Yates, a hardware merchant of Birmingham, England, accompanies Mr. Anderson in his tour of the world. Both are very wealthy.—*Detroit Free Press.*

PEARLSHELL FISHERIES OF QUEENSLAND.

Mr. Saville-Kent, the Commissioner of Fisheries, has furnished Parliament with a progress report on the pearlshell fisheries of the colony. The report states that some of the debatable points in connection with the pearlshell fisheries of Torres Straits have been satisfactorily solved, and contrary to the expressed opinion of the majority of the divers and shelling-station owners it has been successfully demonstrated that with suitable precautions the pearlshell can be brought in alive from the outside shelling grounds and can be laid down and grown in the more readily accessible waters. This discovery the commissioner anticipates will result in the development of the pearlshelling fishery on a far more extensive and remunerative basis than hitherto. The shelling grounds from which Mr. Saville-Kent has obtained the most abundant material and information is known as the "old ground," which is in the vicinity of Mulgrave Island. Concerning the proposed limit of the size of the pearlshell placed on the market, the commissioner reserves his judgment until he has had an opportunity of personally examining the shell freshly gathered from areas in addition to those which he has already visited, but so far as his investigations have extended he is of opinion that a measurement of 8 in. for the newly gathered shell in the rough, or one of 6 in. lengthwise over the white or internal pearly area of the shell, will best meet the urgent need of a restriction being placed upon the present indiscriminate collection of young and immature shells. Due facilities, however, he considers, should be provided for legalising the collection and transport of young living shells for the purpose of artificial cultivation only. Mr. Saville-Kent hopes to furnish an extensive report upon these matters shortly.—*Queenslander.* *

* The report will be looked for with great interest in Ceylon as calculated to aid the hitherto unsuccessful efforts made to cultivate the pearl-yielding "oyster."—Ed.

CEYLON UPCOUNTRY PLANTING REPORT.

THE WEATHER—THE MOORMAN ON THE PROWL—RISE OF PRICES IN CINCHONA—SHORT TEA ESTIMATES AND “SUPPRESSED VITALITY”—COTTON NOT IN SUCH A BAD PLIGHT AS WAS REPORTED—PLENTIFUL LABOUR.

October 31st.

If for many months past we have been having more than our share of dullness and damp, it would seem now as if it were being made up to us by the exceeding brightness of the present weather. Although the wind is from the S.-W.—the feeling in the air is wholly N.-E., as chilly in the shade and as hot in the sun as if it were January. I don't know whether it is the weather or the crop, but CACAO seems to look a little shabby; COFFEE more so; while CINCHONA and TEA are flourishing.

The slight rise in the price of BARK,—which has since been lost, alas!—set the Moorman on the prowl; but as none of them had much speculation in their souls, their offers for what was in store were not very spirited, six cents a pound being the highest they were inclined to go. This bark had been harvested from dying trees, and had been subjected to a rude kind of testing, that of mastication in the mouth of a Moorman! A good bitter flavour is in high esteem with these traders; and I am told that jungle barks which possess this quality have a value among Moormen! And yet what could we do without these pushing fellows? They are ready to bid for almost anything, and although it is not much they offer for out-of-the-way things, still they have always the pluck to offer something, and risk the hard coin.

Black coffee—strippings and such like—has a singular attraction for the Moorman, and as this valuable article gets more and more scarce, its attractions increase. If you are known to have a few bushels in your possession, you have your bungalow besieged; would-be buyers follow you to the most inaccessible parts of the estate; you find them at the store, where they have waited for hours; they meet you in town; stop you on the road, and some of them are prepared to offer twelve-and-a-half cents a bushel over anybody else. The best price I have heard for husk of a fair quality is R5 a bushel, which is a respectable price, especially when you add twelve-and-a-half cents to it.

Are the growers of Cinchona about to share in the general rise of prices? Certainly that product has been “sair hauden doon” for a long time, and those who have stuck to it deserve an innings. I hear that the shipments between this and the end of the year are not expected to amount to much, and that when the home trade realize this there will be more competition, and prices will rise. It is confidently expected that 1890 will see a very much better market for bark, than there has been for a very long time past. If this forecast of the knowing ones turns out true, Ceylon will benefit.

Tea estimates in some districts are very short, and many whose year ends with December will have no chance whatever to recover lost ground. Everybody says it was the cold wind that did it, which lasted so long. One man, writing to his home proprietor and dwelling on the retarding effects of the weather, said that although things were backward, and the flush scanty and slow, yet the trees were full of “suppressed vitality,” and wanted, of course, only the smile of a genial sun to change the condition of things. But the wet cloudy weather continued week after week, and so did the “suppressed vitality,” and the short returns. After a bit the proprietor at home getting wearied began to inquire if nothing could or had been done to liberate the vitality which to his cost had been suppressed so long!

“Suppressed vitality” was as good a reason for these poor returns as could be given, and very fittingly described the appearance of healthy trees which were worried by cold winds. Of course it is perhaps not quite equal in originality to the “virgin subsoil,” which was untouched by taproot; or the “abnormal activity underground,” which was made to explain the slow growth above; but as a decent kind of planter's reason for non-success, and with more than the usual modicum of hope in it, “suppressed vitality” deserves currency.

COTTON, which was said to have been ruined by the abnormally wet season we have just passed through, is not in quite such a bad plight as was reported; a picking is being got, where before there seemed little hope of any return. The change in the weather has been the salvation of this new product.

Labour is plentiful, and more and more Sinhalese turn up for employment. They want a lot of training however, ere they come to see that for a fair day's wage; a fair day's work should be given, but that too will come in time.

PEPPERCORN.

INDIAN AND CEYLON INSECT PESTS.

To the Trustees of the Indian Museum (Calcutta) we are indebted for the first part of very valuable “Notes on Insect Pests,” edited by Mr. Cotes and copiously illustrated. In a prefatory notice it is stated that

The parts of the serial will be published from time to time as materials accumulate. Communications are invited; they should be addressed to the editor Indian Museum Notes, Calcutta.

Correspondence connected with Economic Entomology should be accompanied by specimens of the insects to which reference is made. Caterpillars, grubs, and other soft-bodied insects can be sent in alcohol; chrysalids and cocoons, alive, and packed lightly in leaves or grass; other insects, dried and pinned or wrapped in soft paper. Live insects should be sent when there is a reasonable probability of their surviving the journey. Caterpillars, grubs, and other immature insects can often be only approximately determined; they should therefore, where possible, be accompanied by specimens of the mature insects into which they transform; when, however, this is not possible, they should, still be sent, as they can always be determined approximately, and uncertainty must necessarily arise in discussing insects when actual reference to the specimens cannot be made.

The first description is by Mr. E. T. Atkinson, B.A., C.S., C.I.E., and deals with an insect which is only too well known in Ceylon, as an enemy of rice grains equivalent to the blood-sucking fungus in the case of coffee leaves. We quote as follows:—

THE RICE SAPPER (*Leptocoris acuta*).

Plate 1, fig. 1; a, enlarged, b, natural size.

In 1886, some specimens of an insect, belonging to the order Rhyngota and section Heteroptera, were received from Mr. J. Lee-Warner, of Tinnevely, and were found to have considerably injured the autumn rice. They were identified with *Leptocoris acuta*, Thunb., a wide-spreading species found all over the east on rice. In the North-Western Provinces (Gorakhpur) Chota-Nagpur and Assam, this insect is known as *gandhi*, and in Assam attacks especially the *ahu* rice. In Tinnevely it is called the *munju vandu*, or rice-juice sucker or sapper. There is every reason to believe that the numerous references which are given below all belong to one and the same species or its local varieties. This species is represented in South America

by the closely allied *Leptocoris filiformis*, Fabr.; in Central and North America, by *L. tipuloides*, De Geer; in Africa by *L. apicalis*, Westw.; and in Australia by *Mutusea brevicornis*, Dallas. The general colour of the Indian species varies from virescent (which in old specimens fades to sordid yellow) to testaceous, and even brownish-testaceous: the rings, at the base of the 2-4 joints of the antennæ, vary in the space occupied by them, and, in colour, from white to fulvous and testaceous, and are sometimes very faint; the first joint of the antennæ is sometimes entirely testaceous: abdomen above reddish orange, beneath entirely flavescent or with a row of four brown spots on each side. Those without spots beneath are smaller, and, in the Indian Museum collection, are from Assam and Sikkim; the spotted forms are from Calcutta, Behar, Tinnevely and Ceylon, but in some of these latter specimens the spots are so nearly obsolete as to be barely traceable.

Mr. D. J. Macpherson, C. S., of Bankura, writes that this insect appeared in the sudder sub-division of his district, where it is called *bhoma*, and damaged the early rice crop when ripening (Sept.) In the Proceedings of the Agri-Horticultural Society (18th May 1871) it is noticed that seedlings from some experimental sowings of Carolina paddy were attacked by the *gandhi*, whilst the indigenous seedlings escaped. The pest was also reported from Partabgarh in Oudh, and is there described as greenish-brown, having an offensive smell: it settles on the rice when milky and sucks out the juice, leaving the husk dry: as many as six to ten of these insects have been seen on a single ear. The Deputy Commissioner of Hazaribagh also reports the rice-bug (*Gandhi makkhi*) as attacking the *gora* and *badhi* rice while in the ear; it destroys up to three-fourths of the crop and generally appears in a year when the rain sets in early (May.) The insect in the larval state is most destructive, sucking out the juices from the halm, which withers and turns yellow, but we know nothing of its life-history, how many broods there are; where the eggs are laid and apparently hibernate; whether any attempts at destroying the pest have been made and with what result. Smoking the fields attacked by burning vegetable refuse to windward might be tried, but the area is too large for the ordinary methods of insecticide preparations.

We have seen the Sinhalese drawing ropes covered with a glutinous substance over their fields, to capture this or an allied pest.—Since writing the above, we have received from Mr. Driberg, Supt. of the School of Agriculture, the following response to queries of ours:—

I am sorry that my teachers cannot supply the Sinhalese and Tamil names of the insects mentioned as pests in Ceylon, and they seem to think there are no distinctive names. I enclose a note on the rice sapper by Mr. Jayawardene:—

The rice sapper (*Leptocoris acuta*, or *varicornis*).

Sinhalese name—*gojan messa*, Tamil name—*vandu*. This insect is commonly known in Ceylon as the "paddy fly" but it is a member of the bug family, and possesses the characteristic offensive smell. Perhaps it has gained its Indian name of *gandhi* on account of this offensive smell. *Ganda* in Sinhalese too means a bad smell.

The pest is very destructive to paddy. Sometimes large tracts of fields have to be left without cutting as there is no crop to be gathered, the insects having sucked out the juice while the grains of paddy were still young and leaving the husk dry. On approaching an infested field the presence of the pest may be made out by the offensive smell which prevails. They are found in such numbers in some fields that I have seen the ears of paddy actually bending under the weight of the insects on them.

Both the "yala" and "maha" paddy are attacked. The insects were found in a plot of dholl in the school garden sucking the juices from the immature pods. The insects were found paired on the dholl trees, and a female was placed under a bell for observation and laid eggs but these were very unfortunately destroyed by ants.

There is no doubt that the pest breeds in paddy-

fields, as I have observed the insect in all the stages of paddy plants. An alternative brood is hatched in the jungle when the fields lie fallow.

Methods employed for destroying the pest. 1. *Charming* (!) is resorted to with very great success according to the villagers. Probable explanation of success when each is the case—a change in the weather. High winds and rain drives the pest from the fields to seek shelter in the neighbouring jungles.

2. *Smoking* by burning certain aromatic herbs and resinous substances to windward—very often attended with great success.

3. *Ropes* saturated with resin oil or kerosine oil is drawn over the fields with doubtful success.

4. *Bokugema* which is the only effectual way of getting rid of the pest. A paddy winnow is taken and a glutinous substance, generally the *coagulated milk* of the jak, is rubbed on the inside. This is tied to a long pole and the ears of paddy are brushed with it, when the insects are found adhering in large numbers. The winnow is now held over a fire and the insects killed. The process is repeated over and over again.

CHORA-POKA.

A bottle containing specimens labelled *Chor-poka* received from Mr. R. Cornish, C. S., of Balasore, contained the larvæ of several species of Rhyngchota belonging to different families. The local report states that when the sesamum* crop is gathered and stacked on the threshing-floor, the insects appear in vast numbers and eat out the kernal of the seed, leaving only the husk. To prevent the attacks of the insect, the stalks are steeped in water for a day, and thus induce a partial decomposition which produces a bad smell that appears to be distasteful to the insects and checked their progress. Amongst the insects found in the bottle are the small pentatomid, *Carbula biguttata*, Fabr.,—a species belonging to the family Lygæidæ,—and the larvæ of several species in too early a stage for identification. Is not considered probable that any of these insects are concerned in eating out the interior of the sesamum seed.

THE GREEN BUG. (*Nezara viridula*, Linn.)

Atkinson, JI. As. Soc. Ben., Pt. II, p. 119, (1888).

This cosmopolitan insect, found almost in every country in the world, has been reported as occurring on potato halm in Bangalore (Mr. J. Cameron.)

CAPSIDÆ.

Mr. Atkinson has under preparation a monograph of the genus *Helopeltis*, Sign., to be illustrated with figures of all the described species of this genus. It is well-known to all interested in the tea industry as the 'mosquito-blight;' and would seem to be of great economical interest, both in Assam and all other tea-growing countries. †

Disphinctus humeralis, Walker.

Monalonion id., Walker, Cat. Lep. Het. vi, p. 162 (1873.)

This is another pest belonging to the family Capsidæ, which has been recently discovered attacking the cinchona at Mungphu in Sikkim. It does not, however seem to have done much damage, and has for some time disappeared.

Walker's description is as follows:—

"Red, slender, shining, very finely punctured; head short, triangular, eyes black, prominent; rostrum reaching the intermediate coxæ; antennæ black, very slender; first joint piceous, rather stout, a little shorter than the head; second joint more than thrice as long as the first; pronotum contracted in front, with two transverse furrows, and with a large black spot on each side posteriorly; legs luteous, slender, corium and membrane hyaline, brownish cinereous; veins brown."

Long, 8½ mill. Reported from Malacca.

Notes on mango bugs we do not quote, as mangoes in Ceylon do not seem to suffer materially from

* Ginglyly.—Ed.

† We shall look with great interest for this publication, reproducing the most important portions, for the information of our readers.—Ed.

insects except, perhaps, occasionally in Jaffna. Neither is it now locally important to quote notices of three insects which have attacked cinchona in Sikhim. But we quote what is said about

Dactylopius adonidum, Linn., already described in the Journal of the Asiatic Society (Part II, p. 288, 1886) has been procured from Mysore, where it occurs on *Cedrela* sp., *Aerocarpus fraziniifolius*, *Ficus mysorensis*, *F. glomerata*, *F. asperrima*, &c., and does considerable damage to the coffee bushes. Mr. Anderson, of Barguai (Mysore), has sent some remarkable examples of the curious black fungoid growth which seems invariably to accompany this insect, and, covering the twigs, effectually rots and kills them. He describes it as a black, felted substance, extremely like a fungoid growth: in appearance it is very like the sooty accumulation that occurs on bottles in cellars and which wine-merchants sometimes exhibit *in situ* on bottles, as evidence of the time that they have been kept. That which accompanies the *Lecanium nigrum*, Nietner, in Ceylon, has been named *Trisporium gardneri* by Berkeley, and is described as having at first the appearance of a thin, diluted black-wash, but, rapidly increasing in density, within two or three months it quite covers and blackens the leaves and other parts of the trees, finally almost resembling moss. Its period of growth, in Ceylon, appears to extend over about twelve months, when it is replaced by a young growth, or both it and the scale abandon the tree, and, when leaving the tree, the fungus peels off in large flakes. Mr. Nietner writes:—

"As the occupation of a coffee or any other tree (by scale-insects) gives rise to the appearance of a glutinous saccharine substance (honey-dew, which is either a secretion of the scale, or its extravasated sap that flows from the wounded tree, or, more probably, a combination of both), which disappears with the scale, and as the fungus does exactly the same, I have no doubt that its vegetation depends upon the glutinous saccharine substance."

Mr. Anderson also noticed the occurrence of this honey-dew in connection with *Dactylopius adonidum* in Mysore, and writes that the tree, when attacked, bleeds or gums so profusely that the ground all round the stem is made moist.

Mr. Maskell, in his account of the scale insects of New Zealand, (p. 15), also calls this transparent, gelatinous, fluid excretion, 'honey-dew,' and remarks that it is apparently analogous to that exuding from the Aphides, Psyllidæ and Aleurodida. It varies in quantity with the species present, and appears to be excreted by a cylindrical tube, exerted from the ano-genital orifice after the manner of a telescope, the furthest-extended portion of the tube, being the most slender. In the genus *Coslostoma*, when this tube is pushed out to its full extent, there appears at its furthest extremity a minute globule of yellowish, nearly transparent glutinous fluid, which rapidly expands like a soap-bubble, and then, suddenly breaking off, falls in spray on the leaf beneath, as the coccids are usually attached to the underside of a leaf. It therefore injures the leaf in two ways, by stopping up the stomata of the leaf itself, and by forming a nidus for fungoid growths which rapidly accumulate and kill those portions of the plant on which they appear. Removing the fungus is not sufficient, but in addition, the scale-insect itself must be sought out and destroyed by the kerosine emulsion described in No. 2 of these Notes and which for reference is reproduced here—

"An emulsion resembling butter can be produced in a few minutes by churning with a force-pump two parts of kerosine and one part of sour-milk, or soap solution in a pail; emulsions, made with soap solutions being generally found to be the more effective. The liquids should be at about blood-heat. This emulsion may be diluted with from nine to fifty parts of water, which should be thoroughly mixed with one part of the emulsion.

"The strength of the dilution must vary according, to the nature of the insect to be dealt with, as well as to the nature of the plant; but finely sprayed in twelve

parts of the water to one of the emulsion, it will kill most insects without injury to the plant."

It should be applied through a spray nozzle (see pl. 4, fig. 4)—

"The nozzle which best combines the necessary qualities is undoubtedly the eddy or cyclone nozzle, consisting of a small circular chamber with two flat sides, one of them screwed on, so as to be readily removed. Its principal feature consists in the inlet, through which the liquid is forced, being bored tangentially through its wall, so as to cause a rapid whirling or centrifugal motion of the liquid, which issues in a funnel-shaped spray through the central outlet in the adjustable cap. The breadth or height, fineness or coarseness, of the spray, depends on certain details in the proportions of the parts, and specially in the central outlet.

"To drive the liquid through the nozzle some kind of force-pump is required, and a great number have at different times been experimented with, some of them being of a most complicated nature. It is perhaps not of any very great consequence which particular form is adopted for use in India; but the aquapult force-pump, which has been arranged to be worked entire by one man, who also distributes the spray, seems to be about the best suited for general use in a country where economy in labour is generally not so great an object as economy in the cost of apparatus."

(To be continued.)

COFFEE AND TOBACCO IN JAVA.—The Coffee Company Hansa, which is to be established in this city has opened its subscription for shares. The amount to be subscribed is 200,000 guilders, divided into 2,000 shares each 100 guilders at par. The Amsterdam Tobacco Company, owners of the state Senenbah in Deli, and which imported the tobacco under the brand N. G., has been bought by the Deli Company. The tobacco of this estate was shipped lately to Bremen, but will, of course, now be offered again in this market, which will be a great advantage, as the quantity of this brand is considerable.—*L. & C. Express.*

TEA BOXES.—A rather important industry arising out of the tea trade is the making of boxes. During the past thirteen years the making of tea-boxes in the Valley districts of Assam has increased from 1,384 to 379,089,—this being the number reported as the output of 1888-89. At the same time the import of boxes, which stood at 135,718 in 1875, had gone down to 127,827 last year. Tea boxes are now very extensively manufactured on the various tea estates, where the engines which are used in summer to work the rolling and other machines in the manufacture of tea, are employed in winter to work the saw-benches. But there are, besides, nine saw-mills in the Lakhimpur district and one in the Darrang district, where tea-boxes are manufactured for sale. Some of the owners of saw-mills in the Lakhimpur district are unwilling to furnish information regarding the number of boxes turned out; but the Divisional Officer estimates that about 200,000 boxes are made by all the saw-mills in that district, while the Divisional Officer in Darrang reports that 13,441 boxes were sold by the Tezpur saw-mill during the year under report. Last year Sylhet and Cachar received 23,075 boxes from Calcutta and exported 131,453 containing teas, from which it is inferred by the officials that 108,378 boxes had been made locally, as compared with 47,938 made in these districts in 1875. As in the Valley districts, large quantities of boxes are made on the gardens, and there are also many carpenter establishments where boxes are made for sale. These concerns are chiefly to be found on the banks of the main rivers.—*Englishman.*

CHILAW: COCONUT PLANTING.

A magnificent piece of jungle is shortly to be put up for sale at the Kacheeri and will doubtless find bidders among the wealthy Moormen of the district, though it is said that a European Company is now being formed to buy it. For coconuts, more desirable land could scarcely be found, and the plantations in its vicinity are likely to bring in early and handsome returns to their fortunate proprietors. Our worthy A. G. A. is giving great satisfaction and taking a good deal of pains to promote healthy recreation, such as cricket, tennis, &c., among the townsfolk.—*Cor.*

THE SCARCITY AND WANT OF CATTLE IN INDIA.

It was asserted lately by Sriman Swami that in former days each Hindu possessed about 80 or 100 cattle, but he did not say whence he derived his information, or explain why so large a number of cattle were to be found in India after it ceased to be a pastoral, and rose to the rank of an agricultural country. He stated that for agricultural purposes a great number of cattle are absolutely necessary, and that agriculturalists in India possess on an average only half a cow ahead, whereas in England and America they have 35 and 49 cattle respectively per head. The Indian average he obtained by dividing the number of cattle in India (30,000,000) by the agriculturalists proper, who number 56 per cent. of the whole population and therefore amount to about 35,000,000 male adults. There seems something wrong with the arithmetic here; but even if it were not so, it is not plain how these figures help the argument, for English and American bovine cattle are not kept for agricultural purposes.

Excluding the Lieutenant-Governorship of Bengal, for which statistics are not available, the total Government assessed area in square miles in India is 474,600 of which 223,032 are cultivated, 101,541 are cultivable, and 83,887 are uncultivable. Even the area at present cultivated gives an average holding to each adult male agriculturist of 4 acres, but the difficulty is that land is taken up for cultivation in contiguous blocks, of which little or nothing is left for pasture, and thus, though 30 per cent. of cultivable land is uncultivated, it is too distant to support the cattle on the cultivated land, which is thus not cultivated, as it might be with a sufficiency of well-fed cattle. In some parts of India, therefore there are more husbandmen than the land can feed; in other parts vast tracts of fertile soil still await the cultivator. If the Indian races would but migrate to tracts where spare land still abounds, and thus allow tracts of pasturage and fuel reserves to be interspersed with the ordinary crops in the parts now under cultivation, any number of additional cattle necessary might be raised, and they will also be doing more than the utmost efforts of Government can accomplish to prevent famine, and to enable them to live in plenty and comfort. The introduction of fodder crops as a regular stage in the agricultural course might mitigate some of the evils for a time, but would not be a sufficient remedy. Even with a more even distribution of pasture, this precaution is necessary in such a climate as prevails in most parts of India. Over a great part of the Empire, unless this precaution is taken, the mass of the cattle must be starved for six weeks every year. The hot winds roar, every green thing disappears, no hot weather forage is grown; last year's fodder is generally consumed in feeding the cattle employed in raising the spring crops; and all the husbandman can do is just to keep his poor brutes alive on the chopped leaves of the few trees and shrubs he has access to, the roots of grass and herbs that he digs out of the edges of the fields, and the like. In good years, he just succeeds; in bad years, the weakly cattle die of starvation. But then comes the ruin. Within a week the burning sands are carpeted with rank herbage, the cattle eat and overeat; and ten millions, according to Mr. Hume, worth 7½ millions sterling, die annually of diseases springing out of this starvation followed by repletion with immature herbage. However great a failure model farms may have been, that at Saidapet proved that dry crops can be profitably cultivated for fodder at all seasons of the year. Those most to be recom-

mended are yellow cholam, guinea grass, and horse gram. Sugar-cane and rice also yield excellent fodder when cut green.

There is plenty of land in India for the whole population. What is required is not the diminution of the people by emigration, but their more equal distribution. If British India were insufficient, there would still be the native States.* It is not merely the paucity of cattle that impedes agriculture, but their miserably poor condition, due, among other things, to the want of selection in breeding. This also is a subject on which the Swami might preach with profit. Before leaving the Swami's data to consider his conclusions, we must ask what became of the surplus agricultural produce in the days when the Indian agriculturalist possessed from 80 to 100 cattle! With less than one head of cattle to each agriculturist, and notwithstanding famine and the absence of sanitation the present population does not decrease, but is steadily progressive. Supposing the people in the good old times to have consumed twice as much of their produce as their descendants, twice the rate of cattle possessed by the latter would have sufficed for that purpose, and they would still have had nearly all their 80 to 100 cattle available for the production of from 80 to 100 times as much as they wanted for themselves. What became of this enormous power? Where were the markets it supplied? How was it profitably maintained?

From simply urging the prohibition of the slaughter of cows, the Swami has formulated four other demands, though still maintaining that his first, which is now his fifth proposition to be the measure of the most urgent necessity. How the prevention of the slaughter of 100,000 cattle consumed by European troops can be more urgent than the prevention of ten millions of cattle dying of preventable disease is not easy to understand. As some small help towards the prevention of disease, the Swami's first two demands deserve consideration. These demands are: "To open Veterinary Colleges in every district in order that even the poor ryots may be enabled to learn to administer medicine for cattle diseases," and "to have a veterinary hospital attached to each college." There can be little doubt that when an indigenous staff is obtainable, veterinary institutions will be fostered by Government in every district. Much has already been done to bring about such a state of things. At present the alumni of the Madras College of Agriculture at Saidapet have been sufficient only to man the College itself and to furnish Stock Inspectors to 16 districts. The establishment of hospital pounds was authorised by Madras Act II of 1866, but for want of a trained staff the Act has remained very much of a dead letter, and recently more so than was necessary. When the Department of Agriculture was re-established under Lord Ripon's Government, the necessity for the diffusion of veterinary knowledge was recognised, but, as the operations of the Department, at all events in the Madras Presidency, appear to be languishing for want of personal interest in them on the part of the superior staff, a memorial on the subject cannot fail to be of use by resuscitating the interest of Government in it. The Swami's third demand is: "To repeal the Forest Act, which has closed all the grass land and pasture against the free entrance of cattle, leaving open all the unsurmountable high peaks, which has prevented the poor ryots from freely entering a forest, and cutting down a small tree wherewith to make of ploughs and other implements, and thus has made him too poor to feed his cattle from his pocket; and which by creating a scarcity in the supply of firewood has caused the ryots to use dried cowdung for firewood, and has thus eventually diminished the supply of manure." Besides being destructive of the arguments for the fifth proposal, this sentence contains considerable inaccuracies. The Forest Act did not close all grass land and pasture against either the free or restricted entrance of cattle, and it left more than the inaccessible peaks open. It does not prevent the poor ryot from entering the forests, with permission, as freely as ever, for the purpose of

* Upper Burma could support 50 to 100 times its present population.—*Ed.*

obtaining timber for agricultural purposes, and this therefore, is not the reason that he is too poor to feed his cattle. It was the Forest Act, but the wastefulness of the people themselves and their over-gregariousness, that created a scarcity in the supply of firewood, and incidentally of manure. It is not the Act, but the system of working it that is to blame for its failure to help agriculture as it ought. For many years the Government has been considering the feasibility of introducing a system of village plantations that would not only supply firewood, but yield leaves and an underworth of fodder sufficient to tide the cattle over their struggle for life each summer. In some districts, Government has land of its own which it could thus plant; in others it is only a sleeping partner in the soil. In some cantons of Switzerland the occupiers of commune lands are compelled by law to keep up a certain number of trees. It seems a fair question whether plantations ought not to be made an incident of land tenure in many parts of India. They would go far to solve many difficulties of Indian agriculture. But little can be done in this way until the pressure of population is removed from the overcrowded parts. The repeal of the Forest Act would mean indiscriminate timber cutting, burning of jungles, waste of fuel, the use of manure to supply the place of that waste, bringing pasture land under the plough, and diminution of the rainfall. It would, in short, intensify, instead of modify, the causes of the present three great impediments of Indian agriculture, viz., the paucity and miserable condition of the cattle, want of manure, and want of water. The Swami's fourth demand is: "To repeal the salt law, the terrible rules of which have made penal illicit manufacture of salt in howsoever small a degree, and have thus practically shut the gate against innocent cows, who also require some salt." This would meet with a sympathetic reception, if it could be shown how salt fit for consumption by cattle can be rendered unfit for human consumption, or, failing that, how the deficit caused by giving up the salt monopoly can be made good. In urging his final and real proposition, the prohibition of cow-killing, the Swami asks why, "while the Government have made a game law for the convenience of a limited number of their countrymen, and a fish law for the good of a small portion of the Bengalis alone," there should not be "introduced a special law regarding cows, animals equally useful to the young and the old, to the Brahmin and Pariah, to the King and the vassal?" The laws referred to impose a limited restriction, which would, in special localities, prevent the rapid extermination of the animals in question. But an almost complete restriction of the slaughter, to the point of extermination, of cattle already exists in the laws of caste.—*Madras Mail*, Oct. 28th.

COFFEE IN YERCAUD.

The few wet misty monsoonish looking days last week, seem to have been very general. Bad weather was even experienced in Madras, where the "Times" informed the public, that the N.-E. monsoon had set in very punctually. Its contemporary the "Standard" prophesies that the N. E. will set in on "Deepavali" day with a vengeance. The strong wind and rain up here on the 17th and 18th was from the south-west, and at the end of the week the total rainfall for the year was 77 inches; the average for the whole year being about 68 inches, and we have yet two months before us. The coffee estates as a whole are looking very much better than they ever did, leaf-disease being less than in past years. A discussion is on here amongst the planters, whether this damp weather helps to reduce leaf-disease or does it bring it on. What do your readers say?

COONOR, October 25th.—Our monsoon is rather eccentric. Last week we were deluged with rain—day and night—this week has been fair throughout; with clear starry skies at nights, a suspicion of frost attending the last two.—*South of India Observer*, Oct. 26th.

COFFEE'S TURN NOW!—The *Chemist and Druggist* informs us that in the Berlin *linische Wochenschrift* Dr. Wendel calls attention to the injurious effect of the continued use of coffee. He states that "it is quite erroneous to suppose coffee is harmless, as, after being taken for a lengthened period, it produces a special disease. In consequence of its physiological action, Dr. Wendel thinks that coffee should be absolutely interdicted in all febrile diseases, such as typhoid, tuberculosis, &c.: also in diseases of the brain and spinal cord, in anæmia, chlorosis, &c. The symptoms caused by excessive coffee-drinking are as characteristic as those of morphinism and alcoholism."—What next?

CASTOR OIL AS FOOD.—The Malays must have *pukka* digestive functions, seeing that they use a powerful cathartic as food. We quote from the *Perak Government Gazette* as follows:—"It is not generally known that the oil from the seeds of the Palma Christi forms an article of human food; yet such is the case, and amongst the Malays of Upper Perak and Patani castor oil is commonly used in cookery. Both the variety known to the Malays as *Jarah Lang*, which is the official plant, and another variety, with smooth seed capsules, designated by them *Jarah noir*, are eaten by these people. The seeds are ground up, and supply the place of coconut-oil in the preparation of the Malayan curry or *gulai*. At other times the oil is expressed by an oil-press called *apit surin* before use. It is said that people unaccustomed to it can only eat it in small quantities; but that with use its cathartic effects pass off, and then a man can eat half a tumbler of it with his food without any inconvenience. That such an extremely nauseous oil, endowed with active medicinal properties, should have become an article of diet is certainly a matter of interest, the more so as it is one of the drugs which is held by the medical profession not to lose its power by repeated doses."

THE VALUE OF COCAINE.—In their latest report (9th Oct.) Messrs. [Boehringer & Son of Mannheim give the following interesting information:—

Several statements having been lately made in the daily press calculated to inspire the public with some distrust of Cocaine, an experienced operator whose whole life has been devoted to the study of such substances appeals in Köln. Zeitung (No. 254; 13th Sept. 1889) against such unfounded apprehensions. We give the following extract from his interesting remarks:—"It were much to be regretted if the misuse of Cocaine, and the denunciation in the daily papers of such misuse, should deprive a single suffering human being of the blessing of its salutary influence. Yet such must inevitably be the case, if dread of Cocainism inspire physicians with doubt, and patients with repugnance. There is not the slightest reason for either. Cocainism (*i. e.* the habit of taking Cocaine in excessive quantities) resulted solely from the attempt by Cocaine to counteract the deleterious effects of Morphium injection. Such violent excitement of the nerve-centres has however no connection whatever with the external application of Cocaine in surgery, which in the hands of the capable and practised operator is as innocuous as any other simple operation. . . . More difficult is the production of local insensibility by the injection of the solution within, or below, the skin. Success in such cases is only attainable through arresting the Cocaine in the locality to be operated upon, by locally suspending the circulation. Neglect of this has occasionally caused failure in the application. Another element that owing to the novelty of the subject was also not known or disregarded has done the same. Solutions of Cocaine in water become namely, by chemical decomposition, more rapidly inactive, than in the absence of all clouding or colouring of the liquid, would be supposed, and hitherto no means has been discovered of preventing such change. Hence however the imperative necessity of employing only freshly prepared solutions. In general with Cocaine as with every important remedy the knowledge and skill of the operator form the second chief factor. Where these qualities are present, and a reliable preparation at hand, Cocainism becomes a fiction and Cocaine an inestimable relief to many a sufferer."

Correspondence.

To the Editor.

PENNY QUININE.

London, Oct. 4th.

DEAR SIR,—When, during the last decade, the value of quinine went up to as high as 18s the ounce (at which price a large quantity of foreign make was sold wholesale) this valuable preservative from and curer of fever was only available for the rich; and the traders in the article, from the collector of the wild bark in its native forests or the grower of the cultivated cinchona in the East to the chemist who handed the prepared drug over the retail counter, all enjoyed good profits, and there appeared to be no particular inducement to lower the retail price of quinine.

At the present time, on the contrary, after cinchona has been so largely cultivated during so many years in the East and less largely in the West, the markets of the world have been supplied with quantities of bark so large that they have only been saleable at ever decreasing prices, and lately the prices have been so low that they have meant extinction to many and loss to all growers; whilst the collectors of the wild barks have retired many years since from the collection as unremunerative, and that at a time when prices were many times as high as they now are. The present prices therefore would, if they should continue to prevail long enough, mean the elimination of the growers of the excess of cinchona by a gradual but progressive process. By the action of the law of the survival of the fittest, the growers of the lower qualities of cinchona have already followed the collectors of wild bark and disappeared; and as the growing of a moderately rich bark is now carried on at a loss the growers of this quality must be expected to leave the supplying the market to the growers of the richest varieties, unless the equilibrium of the trade should first have been restored. This process of starving out the producer besides being unpleasant and unprofitable to him is exceedingly wasteful, and this action is not confined to its effect on the grower, for the same process is at work amongst the manufacturing interest.

The mode of extracting the quinine from the bark has also been greatly improved of late years by the utilization of the latest scientific discoveries and of labour-saving inventions with the result of lowering the cost of manufacture and of multiplying the manufacturing capacity of the world, viz. the huge works which have been erected and brought into working order have been capable of turning out far larger quantities of quinine than even the largely extended bark plantations could produce the raw material for. The trade demand for quinine has however never, of late years, been large enough to absorb the quantities actually turned out by the manufacturers, and the manufacturers have, in their eagerness to secure the sale of their own brands, reduced their profits to such a level that many of their number have preferred waiting and watching to working at a loss; and it may be said of the manufacturing interest as a whole, as it may be said of the growing interest as a whole, that the present prices mean extinction to many and insufficiently paid work to all. Thus again the process of starving out is unpleasant, unprofitable and wasteful to the manufacturer, and its action is not exhausted in its damage to this interest, for distributors are also affected.

The wholesale distributors of quinine again have suffered from the (for all practical purposes) unlimited quantities poured out by the factories, which both rendered profit on stock-holding by distributors out of the question and made impossible anything like a good profit on the current sales of the article; in the absence of any extraordinary increase in the consumptive demand.

It is true that the wholesale trade, by largely reducing their rate of profit on the sale of quinine, has secured a certain increase of trade, but that increase has not been anything like

sufficient to make up for the loss by the decreased percentage of profit.

With many, very many, wholesale houses, quinine, which not so long ago ranked as a first-rate article, is now hardly worth doing at all. Thus the starving out process does not suit the wholesale distributor. The quinine retailer's position is hardly more enviable. The chemist who maintains the old high prices to the public finds on the one hand that inferior substitutes creep in and temporarily and for mild cases lessen his sale of quinine; whilst, on the other hand, the stores and the cutting houses, by a slightly lower price, oust him as to the greater part of his possible sales. Thus the retailer at high prices finds his sale rather decrease than increase. The stores man or cutting chemist, on the other hand, whilst he may and doubtless does draw to himself a fair share of the custom of that very limited number of people who have hitherto been in the habit of taking quinine, does not find the increase in his sale sufficient to make the business a satisfactory one. Like the wholesale distributor, his increase in quantity is not sufficient to make up for loss occasioned by lower percentage of profit. Thus the starving out process does not suit the retailer either. The decrease in the retail price of quinine has not been marked enough to reach a class of buyers sufficiently numerous to absorb the increased production of bark; and thus, although consumption has largely increased, and although the trade is a growing one, yet, as a whole, it is carried on at a loss in a wasteful way: that is to say that the brains, capital, and labour employed in the growth, manufacture and distribution of quinine are much worse, very much worse, paid than such brains, capital and labour have a fair right to expect to be paid.

What is the remedy for this state of things? The process of reducing production to the level of consumption is one remedy, and its carrying into effect means the continuance of this bad trade, and of losses to the trade, until the desired object of equalisation of supply with demand shall have been reached or passed.

The other remedy is: To stimulate consumption until it shall have reached the level of production. To effect this, soon enough to be of benefit to the trade, it is necessary, that all sections of the trade should put their shoulders to the wheel and insure that those who require quinine—the inhabitants of India, China, Africa &c.—shall have it in such a form as to enable them both to understand its value and how to use it, and at such a price as they can afford to pay for it, and, at the same time, one at which growers, manufacturers and distributors can afford to sell it.

That the world, with its (?) 1,200,000,000 inhabitants is capable of consuming the present highest annual production of 10 millions of ounces of sulphate of quinine, no one will even question; especially when the 60 millions of inhabitants of the United States do already consume at least 3 millions of ounces.

It does therefore seem to be a pity that a trade with the brains, capital and labour at its disposal which the quinine production, manufacture and distribution possess, should have failed, so far, to solve the problem of bringing together the producers who are commercially dying because they have produced too much quinine, and there should be consumers who are actually, literally and physically dying for want of that very quinine.

In these circumstances and hoping that all sections of the trade will give him sufficient support to make the venture not only a success to himself but a benefit to all, Mr. Rivers Hicks of 5 Savage Gardens, Tower Hill, London, offers to the trade a very great convenience at a rate so low that it can hardly fail to be to their advantage to buy his

PENNY QUININE:

that is such a quantity of sulphate of quinine made up into pills as in ordinary cases will restore health or even, humanly speaking, save life at a price which places this invaluable remedy within the means of the lowest paid of the world's labourers.

Penny Quinine is made up in boxes of the value of one penny each containing for use in tropical climates or for severe cases in temperate climates, 2 pills of each 4 grains of sulphate of quinine; or else 4 pills of 2 grains each; or, for tonic or temperate climate purposes, 8 one-grain pills. Twelve penny boxes are packed in one shilling box, and the particulars are printed in the language of the district for which they are intended, and are made suitable to the requirements of that district.

Stronger pills can be had on application, as horses, cattle, sheep, and dogs, in fact all domestic animals, suffer from fever and feverish colds, and to these animals quinine is just as valuable as it is to mankind, and at the present price there is no reason why they should not have it. Opium smoking.—The only known harmless palliative of the sufferings endured by the opium smoker who wishes to abandon the habit is found in the use of quinine. To wholesale buyers who may be prepared to use their special facilities for opening up new districts to push his pills, Mr. Rivers Hicks will be glad to offer advantageous terms.

To the retailer, the pills will thus be a 50 per cent article; for he will sell for 12 pence that which costs him 8 pence. To the public, they will in many cases mean health restored or even life preserved for the sum of 1 penny.—We are, dear sir, yours faithfully,

RIVERS HICKS & Co.

CEYLON TEAS AND AN EXPERTS' PROPHECIES FIVE MONTHS AGO.

DEAR SIR,—The Dealers' Trade Circular has not proved to be a true prophet: vide extract from an enclosed London tea circular, and to the such sweeping assertions as for instance "For low grades there is no future" exception has and always will be taken by those directly interested in the production of Ceylon tea.

SOUCHONG.

(I. A. Rucker & Benckraft's Weekly Tea Circular, London, Thursday evening, May 30th, 1889.)

Recurring once more to our old text, we extract from the same able Circular, Dealer's Trade Circular, issued we may say broadcast over the United Kingdom, and read and considered by those interested in tea in every town, the following remarks on—

"Ceylon Teas.—Arrivals have been moderate though continuous, and prices remain exceedingly low for all but the very best hiquouring sorts. The last invoice of 'Hoolankande' has beaten record with Broken Pekoe, 3s 1½d; Pekoe, 2s 6½d; Pekoe Souchong, 1s 10½d. This average is very high and should encourage planters to strive for quality instead of quantity. The ruck of common tea that is forced on to an unwilling market, kills all life in the Trade. Pekoe Souchongs at 6d, earthy, coarse and rank; Pekoes at 7d, very burnt, and tasting like charred paper, are not likely to increase the prestige of Ceylon Tea, though they may leave a profit to the importer, if, we suspect, they are often almost refuse from the factories.

"In closing our remarks we venture to predict still higher prices for choice Teas, owing to the absence of Indian Pekoes of high class, and till July the only substitute for fine China Teas must be 'Ceylon.' For low grades there is no future. Stocks of low China and India are enormous and no demand, the only way to get rid of the weight is to virtually give it away the a cost of freight and packages."

RICE CULTURE—PRACTICAL QUESTIONS ANSWERED.

Central Province.

DEAR SIR,—In answer to "Householder."—Hathial which is a seven months' crop and Honderavale a six months' crop yields about 50 per cent of rice on the paddy.

The cost of pounding and cleaning is 2 lahass of paddy to every bushel of rice delivered; or 1-5th the value of the paddy, or about from 20 to 25 cents.

A bushel of paddy is sold from R1 to R1.50 according to season.

X.

RICE CULTURE: PRACTICAL QUESTIONS ANSWERED.

Kurunegala, Oct. 25th.

DEAR SIR,—In the Kurunegala District two bushels of paddy produce one bushel of rice. It costs a villager nothing to convert paddy into rice as the females of his household do the pounding.

The average cost in town of pounding two bushels of paddy into one bushel of rice is 37½ cents.

The ordinary price of home grown paddy in the market averages between 87½ cents and R1, per bushel, and rarely rises to R1.25, except in times of scarcity caused either by prolonged drought or heavy floods.

The ordinary villager in this district has no paddy to sell, all that he gets from his field being used for home consumption. After satisfying domestic requirements, if any paddy remains, it is generally bartered at the nearest boutique, invariably kept by a money-grubbing Moorman, the Shylock of the village, for salt-fish, curry-stuffs etc. Those who have no surplus paddy, barter their garden produce for these village luxuries.

Some of the headmen (who are by the way entitled to what is known as *huwandiram*, a tax on paddy for supervision of fields etc.) and influential villagers store their surplus paddy in granaries, and this paddy they seldom sell, the Kandyan idea being that the best indicia of one's wealth, like the cattle of the old Romans, is his paddy. There are one or two such individuals, who are personally known to me, who would at this moment be worth between R5,000, and R6,000 in paddy alone, which has been stored up for years.

We have no "peddling villagers" in this district.

During reaping time, when almost every thrashing floor has its quota of stocks, paddy is cheap, and if any person desires to sell, which is rarely the case, he will not be able to get more than 75 cents for a bushel. But I have known of instances where paddy has been sold at the thrashing floor for R1.09 per bushel, but this is seldom the case.

There is no such article known as "home grown rice."

The paddy that is generally brought into market is that which forms the share of the Government renters. Boutique-keepers and traders buy up the paddy rents from Government, recover and collect the tythe, which in some cases is one-tenth, and in others one-fourteenth of the produce, and bring it into town, where they either sell it in the husk, or pound and sell it as rice. The pounding process is generally entrusted to indigent village women, who for a livelihood undertake the work.

F. H. M.

No. II.

Western Province.

DEAR SIR,—The information required by "Householder" as to how much paddy is required to make a bushel of rice, and what is the ordinary cost of conversion? I may inform him, that two bushels of paddy (both steamed or raw) are required to convert a bushel of rice, at a cost of 18½c. per bushel of rice.

The ordinary price of a bushel of home-grown paddy is from R1 to R1.32 and rice R2.24 to R2.56.—Yours faithfully,

A VILLAGER.

No. III.

Bentota, October 27th.

DEAR SIR,—The information required by "Householder" as to how much paddy is required to make a bushel of rice &c. may be useful to many. In this part of the island, it is generally admitted that two bushels of paddy produce one bushel of rice, but

this is not true with regard to all kinds of paddy—in those known as “Nandu-wee” it is about one measure less than in the others.

Here the cost of reducing two bushels of paddy to rice is from 30 cents to $37\frac{1}{2}$ according to the cheapness of labour at the time.

The price of a bushel of home-grown paddy is from R1 to R1.50; and rice R2.25 to R3. But good seed paddy can be sold higher than this. The ordinary villagers have no paddy to sell; and they have no money to buy cattle-bones or to pay the taxes, for which they borrow money to be paid in paddy at the rate of 60 cents a bushel.—I am, yours faithfully,

C. D. S.

P. S.—A list of all kinds of paddy in the island known at the present day would be very useful to many. I hope one of the prizewinners of the Matara, Matale, or Kegalla Agricultural Shows will be pleased to publish it in your valuable journal with brief information as to the time for the growth of each, &c., &c.

C. D. S.

No. IV.

Jaffna, Oct. 26th.

DEAR SIR,—In reference to your queries, two bushels of good average paddy make one bushel of rice. Ordinary cost of conversion of two bushels of paddy into rice amounts to—

Boiling and drying paddy and fuel .. 24c.
i. e. The cost of (or value of) two quarts of such rice.
Pounding and winnowing .. 24c.
value of two quarts of same rice.

Products of pounding and winnowing two bushels paddy, viz. about six quarts rice bran or *thowdoo*, is worth four cents. The husks are generally disregarded and thrown away as worthless. Jewellers occasionally pay a few cents for a bushel of it—but there is not any regular demand. In the country the *thowdoo* is given back to the person who issues the paddy for pounding. In the town those who consume rice obtained from paddy on the spot allow the pounders to take the *thowdoo*—and a quart of rice for each bushel of paddy pounded.

As a general rule, however, paddy is not pounded for cash. Boiling and drying are done at home, and women who pound out rice for a living, go and get paddy from householders, and return half as much rice, less one quart of rice for each bushel of paddy pounded out. Thus two bushels paddy equal one bushel rice, and two quarts rice is the *hire* for *pounding* out same—boiling and drying costs the same as pounding. Hence a person giving out two bushels of *raw* paddy would receive back 32 quarts of rice, less 2 quarts for boiling and drying and 2 quarts for pounding out, equals balance 28 quarts, equals cost of cleaning 4 quarts, equals 48c.—Average value of paddy is R1.50 per bushel except at harvest time, i. e. January and February. Then the vassals, serfs, retainers, &c., get generally paid in *kind* viz. paddy. The dhoby, barber, blacksmith, and frequently the farm labourers as well, have their paddy in kind, and proceed to turn it into cash, temporarily glutting the market and meeting the rapacity of the grain dealers, and their creditors. Paddy then goes down to R1.25 per bushel.

Home grown and made rice is not generally exposed for sale except at harvest time, but 12c per quart may be reckoned as its average value.

Rice hulled without boiling and drying would not, certainly at first, command a ready sale. Such rice is described as *raw* rice (“*patcha arisee*”) by the natives, and is held by them to be unfit to be eaten *boiled*. They consider that it should be *soaked*, beaten into flour, the flour baked in a pan over a fire (if to be kept) or cooked into “hoppers” or sweetmeats, if used fresh.

I hope I have answered all the questions.

The information was obtained from those who own fields and use their own paddy and also from those who buy paddy and get it pounded rather than eat Coast rice, which many natives state is unwholesome, having been rendered so in husking, and apt to induce bowel complaints and dysentery.—Yours faithfully,

OLD RESIDENT.

There may be slight variations from the foregoing owing to *local* customs in different divisions, but I think the figures I have given are a fair average.

O. R.

NO. V:—THE EASTERN PROVINCE.

Trincomalee, Oct. 29th.

DEAR SIR,—I beg to state that two bushels of paddy are required to make a bushel of rice, and the cost of conversion is about 25c. for each bushel of paddy.

The value of home-grown and home-made paddy and rice in the village markets and from peddling villagers is R1.25 and R3.37 $\frac{1}{2}$ respectively.

I may add that Messrs. O’Grady and Morphew of Batticaloa contemplate ordering out a mill for the purpose of converting paddy into rice.—I am, yours faithfully,

LANDOWNER.

THE BEST TIME TO PLANT COTTON.

Colombo, Oct. 29th, 1889

SIR,—It is evident that we are now having the interval of fine weather before the setting-in of the N.-E. monsoon, and in a week or two there will be good planting weather for cotton. There have been many experiments made during the past six months in growing cotton, and whilst many have succeeded in producing a fine growth and staple, others have not achieved the same measure of success, partly owing to the fact that the season has been about as unfavourable as it well could be, owing to the excessive quantity of rain that we have had, and partly because the seed was kept too long before planting. The north-east monsoon is, beyond question, the best time in which to plant cotton, and I would urge all who have land ready, to plant in November when the rains begin. The agents of the Spinning and Weaving Co. are advertising seed for sale, and as this is a fresh importation from America, it having just been received by the last P. & O. mail-steamer, the result can hardly fail to be satisfactory to those who plant it. There is also some fresh Egyptian seed available, brought by the “Golconda” last week. This variety I have found very hardy, as well as the New Orleans description. I have topped down my bushes twice to a height of 18 inches to 2 feet, and after two crops they are growing up again more vigorously than ever. I would therefore recommend planters to prune in this manner now before the rains. I am hopeful of seeing a large quantity of cotton coming in next year, and, my desire that the planting season should be taken advantage of to the fullest degree is my excuse for trespassing on your space.—I am, sir, yours faithfully,

W. W. MITCHELL.

TEA PACKAGES AND “WEIGHING NET.”

Colombo, Oct. 31st, 1889.

DEAR SIR,—The enclosed extract may be of service, the information being given in condensed form. Estate owners will more than ever require to use packages of the evenest possible tares and of well-seasoned wood, as a loss in weight on latter might easily involve a loss of 1 lb. nearly on the tea weights.—Yours faithfully,

MERCHANT.

Our object in writing today is to advise you

that owing to the unsatisfactory working of the system of "weighing net," buyers have combined in declining to purchase teas unless "average tared" in the case of factory-bulked teas, and separately tared in the case of London-bulked lots. In order to avoid serious loss of weight, planters should strive to obtain *even* tares and to make them scale (say) 2 ounces *under* a certain full number of pounds; the weight of the tea packed in each chest should be 2 or 3 ounces *above* a certain full number of pounds, *e. g.*, if each package tares 16 lb 14 oz. and contains 50 lb 3 oz., the gross will be 67 lb 1 oz.; the Customs will call the tare 17 lb and in order to ascertain the net will subtract it from *official* gross of 67 lb no ounces,) thus leaving 50 lb.

SALES OF TEA PROPERTIES AND AMALGAMATION.

—We are very glad to see the process—which we have consistently advocated with the tea era—going on, of adjacent properties coming more and more under the same ownership and being amalgamated so far as to have their tea crops prepared in the one factory, rather than by means of the multiplication of factories for every 150 or 200 acres of tea. The latest case of the kind is found in the purchase of Tangakelle estate in Dimbula from our late Governor Sir Wm. Gregory (whose visit to the island may not now take place) by Mr. George Beck, the owner of Henfold, which is close by. Tangakelle has no less than 323 acres of tea at varying ages from two to five years, and as the soil is considered good and the jāt of the plants excellent, Mr. Beck may certainly be congratulated on a good bargain if as the "Times" mentions, he pays no more than £6,000 sterling. Working such a place as Tangakelle with Henfold which has close about 300 acres in tea with an adequate factory and with the prospect of the average of the prices for this year continuing, Mr. Beck should not take long to wipe off the capital cost out of profits. We wish him all success, while regretting that we can no longer number Sir Wm. Gregory among our estate proprietors. At the same time, we feel sure this will make no difference in his hearty personal interest in everything connected with the progress and prosperity of Ceylon and with the diverse classes of the population in whom he took so much interest.—The other recent instance of "estate amalgamation" is found in the purchase of Rosita, the Dimbula estate so long fought over, by Mr. James Hill of Harrington who has gone home to make arrangements in connection with the fine series of adjacent properties he is now responsible for. All these—Harrington, Lochiel, Cameron's Land and Rosita—are situated in the Kotagaloya Valley, one of the most favoured divisions of our upland districts for tea. The total extent of these properties is 1,024 acres, of which more than one-half is under flourishing tea, besides the reserve being admirably fitted for extension, and if all can be worked through an adequate and convenient factory, they ought to constitute as prosperous a tea concern as any in the country. We hear that there is a project for turning the Kotagaloya so as to get a fall of some 35 feet with a large volume of water to drive machinery. This will be a great advantage. The price of Rosita—only 31 acres out of 310 being kept up properly in cultivation throughout the protracted litigation—is £2,710.—We trust to see this process of amalgamation either by purchase by individual proprietors or through the formation of Limited Companies still further extend in the tea districts; for it stands to reason that one well-equipped factory working for 500 to 1,200 acres of tea is likely to do more economical and even better work than half-a-dozen separate factories each preparing for from 150 to 200 acres.

"CHICHA," a South American drink, made by the fermentation of malted maize, with the addition of the leaves of the *primum payaca*, or "sandinio," as it is called in the country, when taken in excess as a beverage produces a feeling of extreme weariness, rendering the patients totally unfit to follow any kind of employment. The effects differ from ordinary alcoholism.—*Chemist and Druggist.*

"PENNY QUININE."—Messrs. Rivers Hicks & Co.'s letter on page 387 may be considered in the light of an advertisement, but he cause is so good and so clearly a philanthropic one, namely that of bringing cheap quinine into universal use,—that we cannot but give it prominence and desire all possible attention to its contents. Besides, the business notice of the "penny quinine" firm already appears in our advertising columns.

"SUNSHINE AND A CUP OF TEA" is the title of a little sixpenny pamphlet shortly to be published in Edinburgh with a view to attracting public notice to the beauties of Ceylon and the goodness of our teas. The writer, Mr. Geo. Russell was out here about six months ago on a visit and called on us to collect information with reference to a paper he had undertaken to contribute to a home magazine, but he writes to us by last mail;—

On thinking over the subject I felt that there was much to be said about Ceylon outside tea culture, little known in Great Britain, and it occurred to me that, with the aid of the information I had received, I might by a few pages of description put together in a popular form, attract others to go out to enjoy all that had given me so much enjoyment. I am therefore giving to publication these notes as a pamphlet, "Sunshine and a Cup of Tea." I think that it will in this form have more readers than in the middle of a magazine.

We are promised an early copy of "Sunshine and a Cup of Tea," and will see how it tastes, for the benefit of our readers.

MERGUI GOVERNMENT FARM.—A contemporary remarks:—"Experimental cultivation has been carried on for some years at the plantation at Mergui in Burma, but, according to the report of last year, it cannot be said to have achieved much success. Liberian coffee was fairly successful, though the plants were attacked by white ants, and the crop was less than in the previous year. Great difficulty has been experienced in introducing the coffee for sale, as the first year's crop, which was sold to a Burman, was not properly prepared, and some persons declared that it was not fit for consumption. When the present Sub-Assistant Conservator of Forests took charge he suggested that the coffee should be prepared by the department itself and sold locally, which was done; and though at first there was some difficulty in finding purchasers owing to the bad name acquired by the produce of the previous year, it was gradually sold off, and the purchasers were all pleased with its flavour. The crop of last year at once found a ready sale at Rs 1-8 per viss, and the supply was not sufficient for the local demand, the coffee being pronounced much superior to that sold in the bazaars. The experiments with Arabian coffee proved a complete failure, and have been abandoned. The cocoa seedlings and plants suffered severely from the attacks of white ants, so that only twenty remain out of 161. Only two of these produced pods, which have not as yet been collected. The vanilla plants grew well and flowered, but the flowers all died without coming to maturity owing to the absence of insects to disseminate the pollen, but an attempt is now to be made to fertilise the flowers by hand. There were 172 tea plants, but nothing is said about their produce and the four cardamom plants all died, while the specially selected seed sent from Mysore did not germinate. As the total receipts from the sale of produce amounted to R272 and the expenditure to R617, it cannot be said that the experiments have proved profitable, but as the plantation only costs such a small sum it is to be continued."

SORGHUM SUGAR.

While in Canada and the United States they have for some years been trying to solve the problem as to whether the common Sorghum is likely to produce sugar. Here in India the plant has been utilised for the production of a fine quality of sugar for generations. The facts, however, in this connection, as in most other instances, have only now been brought to notice. At the meeting of the Agri-Horticultural Society of India, held on the 22nd ultimo, a letter was read from Captain Fred. Pogson, in which he says:—"I sent you from Dehra Dun a tin containing sugarcandy made from the sugar Sorghum of Ajmere. This was the Kowar Jainarain Singh's reply to the fiction that no sugar Sorghum was known to the Ajmere Durbar. In one of my letters I mentioned that this sugar Sorghum was grown for its sugar in the Hariana district as well as in Ajmere, and had been grown for ages. Pray address the Kowar, Didwary, *via* Moradnugger, zillah Meerut, and I dare say he will obtain the seed for you. But mention the A-1 sugarcandy to all concerned."

Thakur Jainarain Singh, on being addressed, sent the following interesting reply:—"As far as I have been able to ascertain, there are several varieties of Sorghum that are sown in the parts of the country called Hariana, to the borders of the Bikanir State, and is styled 'Alapur Joar.' It is of two kinds—one yielding white and the other red seeds. This is largely cultivated, and is the sole saccharine produce of those parts. You are perhaps aware that Bikanir produces the famous crystal white sugarcandy which has no parallel in India. Some years ago I myself cultivated a field of Sorghum. It yields two crops in one season, and is sown in rows in May, in well-manured ground, which requires irrigation till the commencement of the rains. It becomes ripe for pressing in November. After being cut the shoots come up, and the second crop is ready by the beginning of February. As far as I have been able to learn, the cultivation of this Alapur Joar is limited, and serves only for purposes of local consumption, for people do not cultivate it largely owing to the scanty means of irrigation they possess." So far as we are aware this is the first time that this particular Sorghum has been brought to public notice, and it appears to be desirable that the several agricultural departments should experiment with the plant.—*Pioneer.*

A FEW TOBACCO NOTES.

The high prices paid for the much-prized "wrapper" tobacco grown in Sumatra are stimulating production in all parts of the world. Not only are attempts being made to grow similar leaf in Borneo and in other islands of the Malay Archipelago, but American planters are turning their attention to the subject seriously, and are demanding of their Government an increase in the import duties, notwithstanding the large amount of protection they already enjoy. This, of course, is the outcome of the belief that they can themselves grow leaf of equally high quality to that now produced in Sumatra, and also of the rapidly increasing consumption of cigars in the States. That an addition made to the ruling rates of import duty on tobacco in America will effectually shut out the Sumatra "wrapper" tobacco is very probable, but, whether American tobacco planters have the necessary climate and soil to raise such leaf themselves, of course remains to be seen. If they can, we may be quite sure that the present prices paid for this much-valued tobacco will fall, for the acreage now under this plant in the States is enormous. *Tobacco*, a journal devoted to the interests of those who deal in the article, raw or manufactured, published in London, says:—

It is difficult, on this side of the water, to thoroughly realize the magnitude of tobacco production in the States; and its growth, instead of as formerly, being confined to a few of the more eastern ones, is being cultivated gradually throughout the entire Union. Not only is it the staple, *par excellence*, of the country, but it is being rapidly cultivated in place of cotton,

The vast difference in the return to the farmer between the two crops is sufficient to account for this. In Talahassee, it is stated, an average of 170 dols. per acre was obtained from tobacco, as against a rather less sum for the whole of fifty acres under cotton. Another grower realized 189 dols. per acre for his tobacco, and one only 12'40 dols. per acre for his cotton. The danger of this state of things, of course, is that the production will be overdone; and increased production in tobacco invariably leads to decreased quality, for the simple reason that it is a crop requiring close cultivation. On the other hand, European manufacturers may anticipate a fall in prices, for moderate grades at all events.

In these days of keen competition, no large profit can be made long anywhere or in any undertaking, commercial, financial, or agricultural; and the Sumatra planters may make up their minds to be compelled to accept much lower prices later on for their leaf. But any considerable reduction of the area planted with cotton in America—which, however, we do not anticipate—would inevitably benefit cotton growers in other parts of the world. The area under this shrub, however, in the States, is so enormous that it is most improbable that any likely extension of tobacco in preference to cotton would seriously affect the output or enhance the price of cotton. The extent, however, of the trade in "wrapper" leaf tobacco may be judged from the fact that 144,401 bales were shipped from Sumatra alone to Europe in 1887. Taking the average weight of a bale, net at 120 lb., this represents a total out-put of 17,328,120 lb., This certainly is a large quantity, when it is remembered that the greater proportion of this tobacco is leaf specially prepared for use as wrappers. The following statistics taken from the publication already alluded to are of great interest, showing as they do the rapid extension of tobacco cultivation in Sumatra:—

TOTAL QUANTITY AND VALUE OF THE SUMATRA CROP SINCE THE BEGINNING OF THE CULTURE.

Crop.	Number of bales.	Approximate average sale price in cts. per lb.	Approximate total value. Dols.
1865	189	54	16,000
1866	174	41	12,000
1867	224	25 2-5th	8,000
1868	890	51 2-5th	30,000
1869	1,381	46 4-5th	100,000
1870	3,114	44	200,000
1871	3,922	49 1-5th	300,000
1872	6,409	47 4-5th	400,000
1873	9,238	66	1,000,000
1874	12,895	54 1-5th	1,140,000
1875	15,355	61 4-5th	1,560,000
1876	29,030	55½	2,580,000
1877	36,520	45½	2,676,000
1878	48,550	45	3,648,000
1879	57,553	42½	4,120,000
1880	64,964	40 3-5th	4,536,000
1881	82,356	41½	5,792,000
1882	102,050	49½	8,566,000
1883	93,530	48	7,620,000
1884	125,264	52 3-5th	10,900,000
1885	124,718	51 2-5th	10,720,000
1886	139,512	56	13,080,000
1887	144,401	44	10,600,000

Here we have evidence of very considerable progress year by year, the average price obtained showing little or no reduction in spite of an enormously increased production. Whether Ceylon will be able in the near future to share with Sumatra the profits arising from the supply of this valuable leaf remains to be seen. But this can only be settled by a series of experiments carried on in different parts of the country, by men who really understand the work of preparation. Of course, if it were ascertained, as we believe it will be, that in many parts of the island the finest varieties of "wrapper" leaf can be successfully grown and cured, then we may fully expect a considerable reduction in prices. That is the inevitable consequence of increased production. But vast as is

the area in America where such tobacco can be successfully raised, it is doubtful whether the local demand in America itself for "wrapper" tobacco, stimulated by prohibitive duties on imports, will not take off all that can be grown in that part of the world. If we are right in this supposition, then it would leave Sumatra, Borneo, and, let us hope, Ceylon, to supply the European markets with "wrapper" leaf.—Local "Times."

PINEAPPLE FIBRE; BAMBOO SEED; TEA.
From the Proceedings of the Agricultural and Horticultural Society of India for January 1889.

From these we take the following extracts:—

PINEAPPLE FIBRE.—At the request of Mr. T. N. Mukerjee, in charge of the Economic Museum, arrangements were made for preparing some pineapple fibre required by the Government of Bengal. With the kind permission of Colonel Neil, Secretary to the Government of Bengal in the Public Works Department, the Death & Ellwood Machine in the possession of the Society was, for convenience of obtaining steam power, taken to the Sibpore College Workshops. In accordance with instructions received from Simla some leaf was retted at different intervals of from three to fourteen days; those steeped for a longer time were quite sodden and unfit to pass through any machine dependent on a scraping action for clearing the fibre, and even the leaves steeped but three days gave inferior fibre and much wastage. Some 20 lb. of fibre from fresh leaves were prepared, of good quality and appearance. A report will be sent with the fibre for the information of Government.

BAMBOO SEED.—From time to time applications are received for Bamboo Seed, but these can seldom be met for, as is well known, Bamboos flower at long and uncertain intervals. Mr. Gamble, in reply to an enquiry, favored the Society with the following interesting note on the subject—

"The only fairly large bamboos, which flower pretty nearly every year and do not die down after flowering are *Deudrocalmus strictus* and *D. Hamiltonii*. The first is the commonest bamboo in India, and especially in Central and Southern hill regions. It prefers dry hill slopes, and is an excellent bamboo for purposes where a very big long stem is not wanted, but only strength.

"Seed can probably be got occasionally from Conservators of Forest. Mr. Home could probably procure it from Chota Nagpore; but the safest one to write to is the Conservator of the School Circle at Dehra Dun, N.-W. P., who has a regular seed agency. *D. Hamiltonii* is the common large bamboo of the Sikkim Hill slopes. Extending east into Assam, it flowers sporadically most years, and seed might be got by official application to the Conservator of Forests, Bengal and Assam, (Darjeeling and Shillong). It has big stems but thin walls, and is not very strong.

"*B. Arundinacea*, the thorny bamboo, may occasionally be got in flower, so may *B. Tulda*, the white bamboo of the country about Calcutta.

"What I should, in your place, recommend your correspondents to do, is to grow the bamboos they want to propagate by means of offsets. In any part of India where village bamboos are common, the villagers understand how to do it. It is much the best, quickest and safest system. It would probably take 10 years to raise a clump from seed, while it can usually be done in 5, from offsets. In Lower Bengal, the best kinds to grow for useful purposes are *B. Balcooa* (Balku bans), *B. vulgaris* (Basini bans), and the big thorny one, *B. Arundinacea* (Beur bans)."

Mr. Sanford of Porbander State, Kathiawar, in a recent letter referred to a Japanese bamboo introduced by Dr. Brandis, who had distributed the seed. As Mr. Sandford mentioned that some of these bamboos were growing at Somastipore, a station on the Tirhoot State Railway, Mr. Gleadowe-Newcomen, the Traffic Superintendent, was applied to, and gave the following particulars:—"The bamboos were grown from seed received by Mr. Horace Bell, late manager of the Tirhoot State Railway. With a little care and cultivation they grow magnificently, beating any kind I have seen in this country. I have some in my compound

three years' old, or rather in their third year, they are quite 30 feet high and very prolific; I believe they grow 50 feet long. If planted too close they kill each other, but if given room, throw out side shoots from the roots very rapidly. They have not done well in wet places, but require a fairly moist spot."

Mr. Gleadowe-Newcomen also very kindly sent some specimens of the leaves and stems which have been sent on to Mr. Gamble, who is engaged in preparing a work on Bamboos.

TEA ANALYSIS.—A large number of samples of soil and plants have been received through Messrs. Davenport & Co. from the Singbulli and Murmah, Central Terai, Gielie, Ringtong and Chenga Gardens, with full particulars as to class and age of plant and other information. These are too lengthy to be inserted in the *Proceedings*, though valuable for the purpose of the inquiry.

PADDY HULLING.

AGRICULTURAL IMPROVEMENT IN THE BATTICALOA DISTRICT.—We understand that Mr. Fisher, the Government Agent of Batticaloa, and Mr. LeMesurier of Nuwara Eliya, are about to introduce a paddy-hulling machine into the Batticaloa district, and we suppose they will follow on the usual lines of showing the headmen of villages how the machine should be worked, and getting the headmen to induce the natives to use it. The machine which is going to Batticaloa, is of English make, and was for some time used at Hambantota, where we believe the people, as in other parts where it has been introduced, could not be prevailed on to continue using it. It is now being repaired at the Government Factory, and will be sent off to Batticaloa shortly. The idea is to get the natives there to use it; but we have our doubts as to their success, for natives do not take to English machinery, and cannot be got to appreciate it, while the cheapness of their labor renders it very unlikely that paddy cultivators would care to invest in expensive machinery, which would increase the cost of production.—Local "Times."

PRUNING COFFEE.—A Nilgiri planter, a Mr. L. W. Gray, writes a letter to the *Madras Mail*, with reference to the results of pruning on the bearing capabilities of coffee. The letter referred to is as follows:—

Sir,—I am in charge of an estate which has given the following crops per acre—

1880-1881 ...	11 cwts.	1884-1885 ...	5 cwts.
1881-1882 ...	5 "	1885-1886 ...	15 "
1882-1883 ...	10 "		
1883-1884 ...	15 "	Total ...	61 cwts.

—10 cwts. per acre for 6 years.
This I must mention, was brought about by non-pruning, liberal manuring, and irrigation. From 1883 to 1885 the estate was visited by several planters who had heard of the above result, and they all said the place must be pruned, or it would go out. So I tried a small field, and, as the trees did not seem to suffer, I proposed to the proprietor that we should prune the whole estate, and to this he gave his sanction. So in 1886 the pruning took place, and the result of crops has been as follows: 1886-87=3 cwts. per acre, 1887-88=10 cwts. per acre, 1888-89=6 cwts. per acre. Total 19—or 6 cwt. per acre for 3 years. The trees in the above years, viz., 1886-88, at blossom time, put in quite 10 cwts. per acre, but during March or April a large percentage of the bearing wood died back, and consequently I lost my crop. Now, what I want to know is—is this dying back due to pruning, or "leaf disease." Last year, after pruning, the estate looked fit for 15 cwts. per acre, and there is no doubt that that amount of blossom came out, but, as I said before, most of my wood died back. This year we did not prune, and a magnificent blossom has been out, quite, if not more than, 15 cwts. per acre; but the wood is beginning to die back again, and the trees are almost leafless. Until pruning commenced in 1886 this dying back was unknown on the estate.

INSECTICIDE FOR TEA BLIGHTS; TEA SOIL ANALYSIS; SUGARCANE.

(From the Annual Report of the Agricultural and Horticultural Society of India for 1888.)

INSECTICIDE FOR TEA BLIGHTS.—During the year an insecticide, to which attention was drawn at a meeting of the Royal Horticultural Society of London as possibly applicable to tea blights, was reported on. A careful trial was given to this wash on the gardens of the Second Falloodhi Tea Co., through the courtesy of Messrs. Davenport & Co.; but though the insecticide was found to do good, it was only temporary in its action and would have to be used repeatedly for Tea blight, the cost of application alone would be prohibitory. Notice is taken of the subject in this place, as from time to time remedies for tea blights are proposed, and should they take the form of insecticide, the test of their practical use is clearly shewn by the report alluded to; they would have to be applied more cheaply than the liquid tried and they would have to be cheap enough for frequent applications to be made.

TEA SOIL ANALYSIS.—An enquiry of more than ordinary interest to all connected with the tea industry, has been inaugurated. In consequence of certain inquiries regarding the relative values of different oil-cakes as soil fertilizers for tea, it became apparent that sufficient data does not exist as to the requirements of the tea plant and the constituents of the soils in the Tea districts, and that it is therefore impossible at present to select the most suitable manures for the plant on scientific basis. The planting community and all interested in the industry, as well as the Society, are therefore under obligation to Dr. Warden, the Chemical Analyst to Government, who has undertaken to devote his very scanty leisure to elucidating the subject. Arrangements have been made through members of the Society for a supply of materials.

SUGAR-CANE.—Reports were received on Mauritius Sugar-cane, several varieties of which were distributed. The marked difference between those cultivated in Bengal and the Otahite kind introduced by the Society some years ago, insured the success of that introduction, and that variety is found now widely cultivated in all parts of Bengal. The Mauritius kinds recently tried, do not differ much in appearance to some of the varieties already under cultivation, and as a consequence it would have to be demonstrated that their yield in quantity or quality of juice is greater before they will be taken up.

THE SOUTH AFRICAN AGRICULTURISTS' ALMANAC FOR 1889.

This unpretending little volume appears likely to be of great use to the class of whom it is designed, and there are points in it which seem worthy of attention from the Ceylon agriculturist in spite of the very different conditions under which he works. There are several valuable contributions on stock-farming and one each on cheese-making, the vintage, hop cultivation and farm-buildings, besides many minor articles, some short paragraphs and two poems.

Some of the articles are disfigured by the use of language so lofty as to be almost unintelligible. Take this sentence for instance which commences an article called "A Periscope from a Pastoral Plane":—"The horse, his congeners and hybrids being the only exportable, yet the most neglected and the most easily and quickly improvable in many directions, by careful breeding, of all the domestic animals of South Africa, hippic glances, it is opined, may lead these bucolic lines." Shade of John Lyly! what are we coming to when colonial farmers indulge in euphuism such as this. Our worthy periscope's matter is however better than his style would lead one to expect, as when he tells us that the way to improve the cattle of a country is not to commence by crossing with imported animals, but to "grade up" the local breed by selection for two or three generations, then import

a size of a better breed but not too big for the cows you have and cross. This advice appears sound and well worthy of attention from local cattle owners.

Here is a point of some interest to tea planters taken from the article on cheese making:—"The ripening process in the preparation of cheese is nothing but a fermenting process, which takes place in every well-prepared cheese when two main conditions are fulfilled, that is, a measure of temperature and a certain degree of moisture. * * * The consequence of too low a temperature is bad fermentation and slow ripening, whereas too high a temperature hardens the fermentation at the expense of the taste peculiar to the kind of cheese." This might have some bearing on the want of flavour in our lowcountry teas?

The following recipe will be found of general interest, though the first is somewhat vague, as the particular kind of mode is not specified:—"To protect iron garden tools from rusting. If iron garden tools are laid for a few minutes in a solution of soda they will be protected from rusting for a long time, even if exposed continuously to a moist atmosphere." This should be useful for shafting. "To dissolve bones, take a large watertight hogshad and cover the bottom with about six inches deep of dry soil; on this put a layer of bones of the same depth, and cover them entirely with wood ashes; on these another layer of bones, then ashes, and so on till the hogshad is full, leave it exposed to the rains all summer and winter till spring. Then on removing the contents of the hogshad, the bones will crumble to powder under a slight pressure and form one of the most valuable manures ready for immediate use."

With these extracts we will conclude our notice of this book, which really seems to be in the words of its sub-title, "The Cape Farmer's Own Vade Mecum," and which does credit to its compilers, Messrs. Jas. Ferguson & Co., Wynberg, Cape Division.

"FINE QUALITIES FIRM, COMMON NEGLECTED."

SIR,—It is now the general result, upon taking up a Tea sale list, to see the heading of this letter as the summing-up of the whole matter and, upon what the lawyers call the *prima facie* evidence, it would appear that the one and only remedy is to make finer quality teas. Yet upon a more careful inspection of the reports, or what is better, a retrospect of the sales of the past, it will be seen that the fall in price has been relatively greater than in the lower grades.

Of course the purchaser buys whatever he can get at as much below the selling price as possible,—whatever will give him the greatest return upon resale; in other words, whatever he can get as much under its value as possible. Consequently, he can now buy Broken Pekoe cheaply, so he buys it instead of Pekoe and Pekoe Souchong. As an instance of this, I commend your notice to the following, the italics being my own:—

INDIAN TEA SALES

(From William Moran & Co's Market Report.)

CALCUTTA, 18th May, 1889.—The first sales of the season were held on Thursday the 16th instant, a week later than last year. About 4,700 chests, quality ranging from inferior to medium only, were offered, and almost all sold with fair competition. Prices were lower than the opening rates of last year, for Pekoe Souchongs about one anna, for Pekoes from one to two annas, and for Broken Pekoes perhaps rather more.

Reuter's telegrams received since our last report as follows:—Indian Tea.—May 16th—Auctions—Offered 20,000 packages. Sold 15,500 packages. *Fine qualities firm, common neglected.*

The inference drawn from the above is that Broken Pekoe would be something like two annas lower than last year, Pekoe nearly as much, while Pekoe Souchongs are stated to be one anna lower. Now it appears to me that our efforts should be not to pluck too fine; for, as the finer grades are evidently falling much faster than the coarser, we ought to do

our best to maintain them in their place in the market, for if they fail us we shall be in a much worse predicament than at present.

When the Indian and China arrivals come in, and it is found this year, as it was last, that the market is full, then quality all round, inclusive of China and Indian, will get its share of abuse, and the buyer will say, as he has said ever since the time of Solomon, "it is nought." We must all be prepared for a fair run of depreciation from the market. It is, however, satisfactory also to find, as was the case last year, when put side by side with the new arrivals from India and China, that our teas gradually went up. China last year was declared in no way equal to past year's arrivals, and I presume, it will be the same this season. I think we are beginning to know the meaning of all these continual assertions of falling-off. Most certainly, there are times, do what we will, when tea is inferior and it is so difficult to get both strength and flavor if a good flavory tea be sent into the market, strength is the desideratum of the buyers, and *vice versa*. During the last six months "dusty tea" has been the complaint, and many planters have told me they never took out so-called dust as they are doing now, much to the detriment of "strength" and to the improvements of inferior grades.

If fine qualities are to fall two annas when common only fall one, what does it advantage us in the market being firm for fine qualities, even although common may be neglected? It savours much more as though there were a greater advantage to the buyers in the fine qualities; for there may be some hope for the producer of a well-proportioned break, but I see no advantage in sending forward 150 to 200 lb. of high-priced tea per acre of land cultivated, when the further expenditure of 10 cents per lb. would add to it one-third more Souchong realizing, say, 35 cents a lb. That is, as the estate has to be plucked over, whether the extra Souchong comes in or not, it does not actually cost the same to pluck, and as the other tea has also to be made, the making is cheapened also.—W. F. L.—
"Local Times."

THE DESTRUCTION OF INSECT PESTS.

[All the writing about the life history of insects, is as nothing to means of destroying pests.—Ed. T.A.]

INTERVIEW WITH THE INVENTOR OF THE "STRAWSONISER."

At the Royal Show at Windsor this week one of the chief objects of interest is an implement which has been invented for the purpose of destroying insect pests and checking their ravages. After having seen the implement at practical work we obtained an interview with the inventor, Mr. G. F. Strawson, of Newbury, Berks, who is by business a chemical manure manufacturer. His invention has been christened "The Strawsoniser." The fan, which works at the rate of three thousand revolutions a minute, is a leading feature of the machine. The liquid or solid to be distributed is placed in a hopper or tank, as the case may be, and by the strong current of air it is driven out in a finely divided condition, covering the plants or land with a fine film which destroys the dreaded fly.

"Will you explain, Mr. Strawson, how your invention has come about?" "I have worked for several years with the object in view of checking the ravages of the turnip fly. I began by seeking for remedies for the insect pest. I first of all found it necessary to have substances extremely fine, or otherwise it would take tons to cover the acre, which would be both costly and less effective. Then I thought of a liquid, which is, of course, capable of infinite subdivision. Next I began to devise a machine which would distribute these substances or liquids in a thorough fashion. I regarded these as the essential conditions to work upon, and I have persevered until the implement you have seen has been produced; and for the destruction of the turnip fly it is a complete success. This is the first time that effective means have been devised for dealing with this pest, although it is a hundred years since it was first noticed." "Were you helped at all

in your efforts by agriculturists?" "I received practically no outside assistance." "And yet their losses from the fly are serious?" "Enormous. From the turnip fly alone the loss in a year in the United Kingdom must amount to a million sterling, and from other pests it will run up to several millions. All the papers say that this is going to be an 'insecty' year, and from many quarters I have been receiving telegrams asking if I can send out machines immediately. The hop growers are anxious at the present moment. Fruit trees are constantly being damaged by caterpillars and other insects. In short, every department of agriculture suffers more or less, and there is nothing more desired than an effective implement to check the attacks of pests."

AN AUTHORITY OPINION.—"Have you had any official pronouncement upon the capabilities of the machine?"—"In an official report just issued by the Agricultural Department dealing with the mangel wurzel fly, the use of the 'Strawsoniser' is recommended. Miss Ormerod, the consulting entomologist of the Royal Agricultural Society, has also reported very favourably upon it. She includes in her report two notes of successful work on badly infested fields, one by Mr. W. Geo. Mount, M.P., of Wasing Place, near Reading and the other by Mr. Geo. Budd, of Mousefield Farm, near Newbury. Both found that the distribution of paraffin and lime were efficacious in destroying the fly. Miss Ormerod herself writes as follows, and in doing so explains the principle of the machine:—"The great point in method of distribution of dressing which makes the apparatus (as far as is at present shown) appear likely to meet many insecticide needs is, that, by means of a tremendous blast of air obtained by a gearing from one of the driving-wheels of the machine, the dressing, whether dry or wet, can be sent up in a cloud-like smoke or mist, of such fineness that when it settles on the leaves it covers the surface completely and delicately, like a fine hoar frost or fine spray. Thus all the exposed surfaces can be lightly and thoroughly covered, and the insects also struck much more effectually than in hand-dressing; and, further, I am informed that the underside also of the leaves may be reached by the powerful current of air (and whatever the air is made to carry with it) which can be thrown from the distributor."

THE EXISTING MEANS UNSATISFACTORY.—"There are of course various kinds of machines at present in use?"—"Yes, but in the case of the turnip fly farmers have almost given up attempting to cope with it. They have been accustomed to drag tarred cloths over the ground, and to roll and harrow it, but they rarely saved their crops except when drenching rain came. As the attacks are in hot, dry weather the crop only lasts a few hours. What was a splendid promising crop in the morning is ruined at night. It is a question of speed when you have these attacks, and the great merit of these machines is the sweeping rate at which they cover the ground. Under favourable circumstances twenty to twenty-five acres can be covered with lime in an hour, while with paraffin one gallon to the acre has been perfectly effectual, the distribution being at the rate of six to eight acres per hour. In dry weather the lime being so finely distributed is apt to be blown away, but paraffin has been successful in every case I have tried."

"Do the vine and hop growers look to your machine for a remedy against their special pests?"—"They tell me in France that it will be of ten times more value there than in England. The French Government, in view of the value that it promises to be to viticulture, have arranged for trials near Paris."

DISTRIBUTING ARTIFICIAL MANURES AND SOWING SEED.—"To utilize the machine as a distributor of artificial manures was a development of your original idea?"—"Yes. Having adapted it to dressings obnoxious to insect life, I saw that it would be equally useful as a distributor of dry artificial manures. Guano, phosphates, superphosphates and basic slag can all be distributed with a regularity and economy which cannot be attained by hand which has practically been the method hitherto. As small a quantity of nitrates as 28lb can be distributed to the acre. Hitherto the loss on nitrate owing to unequal

distribution has been at least 10 per cent., and sometimes it has been immensely more."

"And a still further development was the utilization of the machine as a broadcast sower?"—"That is so. As a broadcast sower I know nothing to equal it. Anything, from the finest seeds up to maize, can be sown by it, and it scatters from 6 to 8 yards."

FOR USE IN TOWNS.—"Then you have town purposes in view as well as country?"

"For sanitary purposes it will be of very great utility. A gentleman from India who spent an evening with me said it would be the saving of an immense number of lives in cities where there were epidemics caused by total want of cleanliness in the streets. A liquid disinfectant can be scattered with the greatest ease and rapidity by the machine. But here, also, there is scope for it. The price of the horse machines will be about £30, and the hand machines, for coffee and tea plantations and horticultural purposes less than a half. I have altogether seven different kinds of machines showing at the show of the Royal at Windsor."—*Pall Mall Budget.*

BRACKEN FERN FOR MANURE.

By MR. JOHN HUGHES, F.C.S., 79, MARK LANE, E. C.

[Mr. John Hughes of Mark Lane writes on July 12th:—"I enclose a cutting from this week's *Mark Lane Express* which contains information respecting the value of Fern as a source of manure, which I hope may be useful to many planters anxious to improve the crops yielding properties of their Tea estates."]

The agricultural value of the common bracken fern for littering cattle and subsequently as a source of manure, is not as well known among farmers as it deserves to be. Year by year arable land is laid down to grass, and the difficulty of providing plenty of litter for stock becomes greater. Peat moss and sawdust are at present used in many of the London stables as substitutes for straw, which is getting dearer every year. It is true that in parts of Wales and Scotland the bracken fern which flourishes with such luxuriance in certain localities, is occasionally cut and used as litter; but for the most part its value for this purpose is not generally recognised, and acres and acres of land producing scarcely anything else but this fern are allowed to remain unappreciated.

With a view of making known the chemical composition and more particularly the richness in nitrogen and potash, the following analysis of fern cut green during early summer, and dried, as usual, by exposure to the sun, was made. Also, side by side, for the sake of comparison, an analysis of the same kind of Bracken fern, cut in March, when quite brown in appearance, the leaves withered and the stalks hardened into wood.

ANALYSIS OF BRACKEN FERN.

	No. 1.	No. 2.
	Young Fern.	Old Fern.
Water	11.66	14.90
* Organic matters	83.38	80.54
** Mineral matters (ash)	4.96	4.56
	100.00	100.00
* Containing nitrogen	2.42	.90
" silica	1.60	2.81
** Containing potash	1.15	.10
" soda64	.26
" lime44	.62
" magoesia13	.47
" phosphoric acid60	.30

It will be noticed that the fern, when cut young and green, contained in its sun-dried condition more than twice as much nitrogen and 10 times as much potash as the old fern full grown and matured. Chemists are aware that the proportions of nitrogen and potash decrease as the leaf matures and the sap goes down, while the proportions of lime and woody fibre increase.

If, therefore, the farmer wishes to take advantage of these facts, he will cut the fern before it reaches the period of maturity, say in June or July.

By so doing he will obtain a material softer, and, when properly dried, more suitable for litter, and at the same time, very much richer in the constituents required to make a valuable manure.

How valuable the manure made from well-rotted fern should be, a glance at the following table will show.

One ton of the following contains, at the time of harvest, in round numbers:—

	Bracken	Wheat	Barley	Oat
	Fern.	Straw.	Straw.	Straw.
	lb.	lb.	lb.	lb.
Nitrogen	54	8	11	12
Potash	26	13	22	23
Lime	10	6	8	8

The Bracken, it will be seen, contains far more nitrogen, potash, and lime than either wheat, barley, or oat straw, and it seems a great national loss that tons and tons of so valuable a fertiliser should be neglected in a country which consumes annually thousands of tons of imported manures, such as guano and nitrate of soda.

One ton of ordinary sun-dried fern contains as much nitrogen as 328 lb. of nitrate of soda, or 600 lb. of best Peruvian guano.

[We have long been aware of the richness of the common fern in potash, but Mr. Hughes gives us a new view of its wealth in nitrogen. Ferns are largely used for shading purposes, and planters will do well to utilize the plants when green as cattle shed bedding or as constituents of manure heaps.—Ed. T. A.]

DELI AND LANGKAT TOBACCO COMPANY.

The statutory general meeting of the Deli and Langkat Tobacco Company, Limited, was held on the 1st inst. at the Cannon-street Hotel, Mr. J. Berry White being in the chair. A special meeting for the purpose of altering the title of the Company followed.

The Secretary (Mr. John T. Zorn) having read the notice calling the meeting,

The Chairman said: Gentlemen, this is a statutory meeting which is held in compliance with the provisions of the Companies Acts, which enjoin that a general meeting of the proprietors shall be held within four months from the date of registration of every company formed under the Limited Liability Acts. As a rule, the proceedings are purely formal, no report or accounts being presented; but in the case of this company, the business of to-day will be something more than formal, for, as you are aware, the company took over the properties in Sumatra as a going concern as from February 4 last, but as the crop of tobacco of last season had not been shipped, we agreed to take it over as stock-in-trade, paying the vendors of the estates the actual cost of production, and taking the risk of any profit or loss that might accrue from the sale of it. Well, gentlemen, within the last six weeks this crop has been arriving in Amsterdam very rapidly; 2,741 bales have been landed there, out of which 2,127 bales have been already sold, and have averaged the satisfactory price of 154 cents. per lb., or the equivalent of 2s. 6 4-5d. sterling. Advances have been received of the shipment of 1,246 bales additional, which should arrive within the next fortnight; this makes nearly 4,000 or more than four-fifths of the entire crop stated in the prospectus. The first invoice ought to arrive within the next two months, and as the tobacco is ordinarily sold within a few weeks of the arrival in Holland, we ought to be in a position to know what the exact profit on the crop will be at the latter end of August, or early in September. As the average of the sales, so far, has been more than 4d. per lb., over the estimate given in the prospectus, being 2s. 6 4-5d. against 2s. 2 1/2d., and as the unsold moiety of the crop is said to be quite equal, if not superior, in quality to that already sold, the profit ought to be at least equal to that foreshadowed in the prospectus. Of course, produce markets vary greatly, and the remainder may not average so high a price;

but our latest advices are of a fairly satisfactory character from Amsterdam, and report that the market there keeps good for all light coloured tobacco of the quality of which the bulk of ours consists. But even taking into account the possible fluctuations of the market, the entire crop ought to realise about £72,000 and as it cost £42,000 to raise, it should leave something like £30,000 the profit balance in our hands for disposal. (Cheers.) So that about the first week of September next, if the transfer of the estates is then completed, we should be in a position to announce to you the payment of an interim dividend for the half-year concluded yesterday. This will be, of course, at the rate of 7 per cent. on the preference capital, and on the ordinary shares should be at a rate more satisfactory than is usual in companies recently formed. Gentlemen, this is very gratifying to myself and colleagues on the board; for, before allowing our names to be placed on the prospectus soliciting your subscriptions, we took the utmost pains to sift every statement made, and to verify the figures put forward. We did not rest satisfied with the evidence and documents produced by the vendors and promoters; but those of us who are connected by business or otherwise with the East instituted private inquiries as to the condition of the properties, and all of which fully supported the statements of the vendors. I was fortunate enough to know a high official who had served under our government of the Straits Settlements. He had visited the Deli and Langkat districts frequently, and knew the estates well, and his opinion was that our three properties—Rimboen, Lingga, and Taboeran—were about the best in Sumatra. So much regarding the crop of 1888, which may now be regarded as an ascertained quantity, and you will doubtless be anxious to learn something of the current year's crop. From the latest advices received by us from Sumatra, transplanting had been going on for the last two months, and it was expected that the whole would be finished early this week. The area prepared for cultivation was 1,095 fields as against 824 last year; so that, given equally favourable climate conditions for growth and preparation and as good a market, the results from this year's crop should be about 25 per cent. better than last year, both in quantity and money value. To raise and cure this effectually we have the ample labour force on the estates of 1,192 Chinese coolies, and as the practice is to work by contract, each coolie taking a field, we have a sufficient margin for sickness or casualties. I would like now to say a few words which may be of interest to you regarding the prospects of the tobacco industry generally, and I do so with great diffidence, because there may be some gentlemen in this room who have been engaged in tobacco planting in Sumatra itself, and can speak as experts. The Sumatra tobacco industry is a very young one, for it only attained its majority this year. Twenty years ago the whole exports from the island were less than 300 bales, and sixteen years ago the whole crop was not so much as was turned out by our estates last year. So far as I can ascertain—and I have made it my business to inquire from experts and others in the tobacco trade—there is but little prospect of a fall in value. It is a peculiarity that almost in direct ratio with the increase in production has been the increase in the selling price. The only point, then, we have got to fear is the possibility of rivals in other places, or in the island of Sumatra itself. The peculiarity about tobacco, which most of you are probably aware of, is that choice qualities can only be grown in very small spots all over the world. Chemists and naturalists are not able to say why this should be the case, but it is undoubtedly so. In the island of Cuba, which is a very large island, there is only a very small tract which raises the choice tobacco, and which has made the Havana cigars so famous; and in India, where the best part of my life has been spent, although a vast country—as big as Europe, excluding France—there are only one or two districts where fair smokable tobacco can be grown. The same applies to Sumatra, the third largest island in the world; there are only a few places, comparatively speaking, where t

peculiar wrappery tobacco can be produced. We have nothing to fear from competition there, but a little rivalry has sprung up in British North Borneo. I was one of the Commission of the Indian and Colonial Exhibition, and I remember with what a flourish it was said that this wrappery leaf tobacco was being produced there; that is four years ago, and since that time some twenty-five companies have been formed for working tobacco in North Borneo, with a capital of close on £2,000,000, and I have not yet heard that there have been any commercial successes whatever from it. None of these companies, so far as I know, pays a dividend, and I do not believe many pay their working expenses. Thus I think that, so far as British North Borneo is concerned, we may make our minds quite easy that they are not going to hurt us with regard to our estates. On the other hand, I believe we shall be able to work in the future on a larger scale, and the cost of production will be much less than in the past. One of the chief causes of expenditure was the importation of Chinese coolies, the cost of which used to be put down at \$100 a head—that is for adult—and they only stayed for from three to five years, so that represents a considerable expenditure. Lately, however, a convention has been formed between Holland and China which admits of the importation of Chinese emigrants into Sumatra, and we are fortunate enough to have on our board Mr. C. L. Grant, who is a member of one of the leading houses in Hong Kong, and we shall, no doubt, be able to get facilities and assistance to put labour on our estates much cheaper than could be done hitherto. (Applause.) With regard to the transfer of the estates, we are doing everything we possibly can to hurry this, but I believe the Dutch colonists are not very rapid in their movements. We are advised by our legal adviser here, Mr. Slaughter, and by the highest legal authority in Holland, that very little delay is likely to occur. One thing likely to hinder us was this—we ascertained, quite recently, that there was a small local company named the Deli and Langkat Tobacco Company, and the Dutch colonial authorities were likely to take exception to our title, although, of course, there would be the difference between the Dutch and English names. However, to prevent any possibility of delay in that way we were advised to alter the name of our company by prefixing "British" before the other words, and that is the reason for our calling you together a little earlier than we should have done otherwise, so that we could effect the necessary change in two meetings instead of three. As soon as we have got the transfer we will make an application for a Stock Exchange quotation, and as we have complied with every rule and regulation of the Stock Exchange, I should think there is very little doubt about our getting it. There is only one other matter which I would wish to mention. When I was offered the chairmanship of the company by the favour of my colleagues I hesitated for some time to accept it, because I knew there were many of them of greater experience and better adapted to fill the post; but when it was pressed on me I accepted it, because I had that which the others might not be able to have—the advantage of going to the East once every two years. In January next I leave England, and will make it my business when abroad to visit the estates in Sumatra. (Applause.) In working other properties in India and elsewhere I have found it of the greatest advantage that those who control the administration should know all that goes on, and make themselves acquainted with the conditions under which the properties are worked, and that they, generally, should be in touch with the men who represent them at the property; and I thought this of so much importance, that I accepted the position of presiding over this board solely on this account. (Hear, hear.) I have nothing more to add now, and beg to formally propose this resolution: "That, subject to the approval of the Board of Trade the name of the company be, and is hereby changed to the British Deli and Langkat Tobacco Company, Limited."

Sir Alexander Armstrong, K. C. B., seconded the motion, which was unanimously agreed to.

The proceedings then terminated.—*London and China Express*, July 5th, 1889.

THE AVERAGE YIELD OF PADDY
AND THE CHALLENGE.

(To the Editor of the "Examiner.")

24th June.

Sir,—I have just received your valuable journal of the 24th intimating Mr. Green's acceptance of the challenge on the conditions mentioned by him. Though it is very late at night now, yet, true to my promise, within three minutes of my seeing your journal, I pen the following lines placing all the information available at the disposal of the Director and of the Editors, lest the good Director should afterwards say he had been taken in by me.

I,—with reference to the conditions, I said, "There are four kinds of lands in Batticaloa, viz (1) rain-fed, (2) stream-fed, (3) village-tank-fed, (4) Government-tank-fed fields. I will offer from 25 to 50 acres of each of these descriptions of lands in different parts of Batticaloa amounting in the aggregate to 200 acres of excellent, good, bad, and indifferent fields." The whole of the 200 acres having been included in calculating the average, the whole must be taken up; for otherwise,

(a) What is to be done with the cast-off portions? Mr. Elliott's Wanniahs will naturally select the cream of the fields and may deprive the other cultivators of their share of water-right &c., or the latter may do the same, and there will be no end of disputes every fortnight.

(b) There is an important point involved in this, for out of these 200 acres about 12 per cent or more are highland portions that should never have been included in Mr. Elliott's Assessment. Having first exercised his own judgment in the matter, he now compels the owner to pay the tithes all the same. For the whole of the 200 acres, I will abide by Mr. Elliott's own estimate of acreage and Mr. Elliott's own rate of Assessment as found in the Records of Mr. Elliott's own Report; indeed, my demand of 750 Bushels is based on calculations about 20 per cent less than Mr. Elliott's.

(c) Should the Director feel that the cost of cultivation is too heavy for him to take up the 200 acres, I think I can arrange with the present leaseholders or others to supply the ordinary capital and labour at the usual rates for about 50 acres or more. Labour, of course, is cheap and available, but the Agricultural Instructors or others must be held responsible for the work done by the labourers and give them their due without stint.

(d) The average has been calculated for the whole of the 200 acres of different kinds of typical lands, not necessarily all of the same acreage, but just as they are found in the Government Register. I cannot add to or take away from any of these, just as I cannot alter the tax due to Government. There is one portion the rent alone of which is from 10 to 13 bushels per acre; it is the inclusion of other lands of inferior quality that brings down the total rent to 750 bushels for the 200 acres.

(e) It is also right for me to let the Director understand beforehand, that there are about 25 or 30 acres of the 200 not cultivated for a year or two, because Mr. Elliott's assessment has broken its backbone. It is the duty of Mr. Elliott to get this typical portion also cultivated, and not only make up his total average, but also pay the rent and the Government Tax, which he so rigorously exacts from the owner now. This would prove the accuracy of his calculations as applied to large areas, which he has himself reported as cultivable and as capable of yielding a certain rate.

II.—As for my name, it will be made known in due course all right; for I am as much interested as others in finding out the truth of the matter, and shall rejoice to see myself defeated, if my fellow-countrymen would be benefited thereby.

III.—The rent of the land is not 3½ Bushels per acre, it is only a slip of the pen for 3¼ Bushels

for you will find me reiterating 750 Bushels for the 200 acres.

I am not going to make these two innocent gentlemen a cat's paw of, and use them to open up new lands for me. These are well-known properties that have been in the family for 10, 20, 40, and 80 years or more. As these are "typical portions," a few of the village-tank-fed fields may, in some seasons of excessive drought, go uncultivated, in which case of course a proportionate share of the rent will not be due to the land owners nor any tax to Government; this portion being under Crop Commutation. But the native subordinates are to be guarded against resorting to the device of not cultivating these portions, simply to swell the rate of yield of the rest. They should wait for the time when the "Vattai" is sown and then add the rent to make up the 750 bushels demanded.

IV.—From the nature of things, it is not possible for me to find all the four kinds of lands near the town of Batticaloa. Here are the actual lands on which I have been calculating the averages:

(1) Rain-fed, 64 acres, (2) Stream-fed, 56 acres. Within a radius of 10 miles from Mr. Elliott's Residence. (3) Village-tank-fed, 55 acres, (4) Government-tank-fed, 25 acres. Within a radius of 5 miles from the present Agricultural Instructor's Lodging.

Total 200 acres, rent 750 bushels @ 3½ bushels per acre. For damage by drought and floods and flies and caterpillars, I am not responsible; for, surely, Mr. Elliott must have made allowance for all these contingencies when he assessed these lands, three-fourths of which are for annual commutation. This is the gist of the contention. For the agricultural capitalist is pretty sure of losing one-eleventh of his working capital every year unless he lays by a "Famine Insurance Fund," as suggested by Sir James Caird for even the more highly-favoured cultivators of India. It would perhaps be better for the Director to consult Mr. Elliott before accepting the challenge as a whole. I must stick to the 200 acres, as I have calculated the average for the same. But no one would be more pleased than myself to see my conclusions utterly falsified by their well-directed experiments. Any further information on the subject I am ready to give.—Yours truly, A TAMIL CULTIVATOR.—Local "Examiner."

VEGETABLE PRODUCTS OF BRAZIL.

The *Pharmaceutical Journal* publishes a paper entitled "Floral Features of the Amazon Valley," by Dr. H. H. Rusby, being a lecture delivered at the Massachusetts College of Pharmacy, March 6, and extracted from the *New England Druggist*, April. We quote the last part as follows:—

Some of the productions of this region are of great importance, and I am sure that a brief consideration of them will not be wearisome to you. Chief among them is indiarubber. The possession of a fine rubber estancia is like the possession of a goose which lays daily a golden egg.

The rubber forests are open to pre-emption by all comers, provided they do not trespass upon the domain of another. A man may take up as much land as he can work. His claim is established by cutting a pathway through the forest from one tree to another, and portioning out the care of the trees and the collection of the product among his men. Each district of forty trees constitutes an "estrado," and each man can manage from two to five "estrados" according to his industry and the proximity of the trees. Each man is furnished with a number of little tin cups, holding about a gill, and a small picking instrument for making incisions in the bark of the trees. He selects a spot upon the tree where the sap will trickle down as he desires and rapidly picks a few holes just through the bark in such a way that the sap will flow from one into another, and all in turn into the tin cup, which he dexterously inserts beneath some scale of bark or attaches by means of a little ball of mud, which he carries for this purpose. Twice a day he visits his trees and col-

lects the sap into a large tin bucket, which is then carried to the smoking place and deposited in an immense copper cauldron. For the smoking fire certain substances are greatly preferred to others, probably because of some curdling ferment which the smoke contains. The most preferable is the fruit of the muticu palm. This is an abundant species in most sections, and exceedingly useful. Its leaves serve for thatching, its bark fibres for cordage, its tender heart portion for making an excellent salad, and from its nuts is expressed an oil which is valued as a substitute for butter, and which is said to have no rival as a dressing for the hair.

Next to these the smoker prizes the outer husk of the Brazil nut. In any case he inverts over the fire a large earthen bowl so as to exclude the air. A small opening is made for the exit of the dense smoke which results. The sap in its original condition exactly resembles milk, and indeed it is a true milk in its composition. Fatal accidents have resulted from this dangerous resemblance, for the milk taken into the stomach soon becomes converted into a mass of rubber. Into the cauldron he dips a small wooden paddle, shaped like a spoon, but with plain surface. In an instant he has the dripping utensil over the column of smoke, turning it skilfully and rapidly so as to prevent the running away of the precious fluid. As soon as it is firm enough to stay without running it is again dipped, and the process repeated until upon the paddle a ball of rubber of from fifteen to seventy-five pounds has been formed. This is then slit up and removed from the paddle. It afterwards loses much weight by drying, and if sold at once a large discount must accordingly be made. The daily yield of a tree is about 2 or 3 gills, and it is estimated that from 25 to 75 pounds of rubber per week should be obtained for each man employed. It is clearly, therefore, a question of men, and the rubber gatherers are willing to pay good prices to anyone who will bring these men to work upon their estancias. So sure a business is rubber gathering that almost any merchant of Para will loan money or advance goods to anyone who is going up the river to gather rubber, the amount being in regular proportion to the number of men that he is taking with him. I know of one man who boasts that his rubber station yields him a gross income of \$500 daily. But he has two hundred men. Rubber gathering constitutes by far the most important industry of the Amazon valley. It is in fact several times greater than all the other industries combined.

An important industry during January and February is the collection of Brazil nuts. These nuts begin to fall as early as October, but the regular season is in the months named. The tree flourishes just where the rubber tree is found, and during the season all other work, even rubber gathering, is given up for this work. The nuts, as we know them, are contained from ten to twenty together in a large case resembling a cocoa, which has to be cut open before the nuts can be obtained. The work of collection is by no means a safe one, the heavy cases often falling from a height of one, even two hundred feet, and instantly killing anyone upon whom they may fall. The collectors often protect the heads and shoulders by means of heavy umbrella-like shields. Statistics of the extent of the export of these nuts are quite surprising. The amount reaches to entire ship-loads. They are not only used for eating purposes. Brazil nut oil has many uses in the arts. In their own country they form a much more important article of food than among us. Various prepared they enter into the composition of many delicious table dishes. Nor are they without medical interests. In that mild climate Brazil nut oil serves a purpose very similar to that of cod liver oil among us. I have seen undoubted recoveries of consumptive patients to whom nothing except unlimited quantities of this oil had been administered. But it would scarcely do in our climate.

Referring to the vegetable wealth of Brazil, it is to be considered that as yet it is almost wholly unknown, notwithstanding the vast revenues that it has already yielded to that country. The history of all other countries has been that very shortly after the dis-

covery, the settlers have begun to develop their agricultural resources. Not so in Brazil, at least in the Amazon valley. Beyond a small—a very small—fraction of the food supply necessary for its own people, this valley furnished no agricultural products. All the energy and enterprise of those who have resorted there has found full scope in culling out the richest of Nature's unaided productions. And even in this direction we have merely entered upon a knowledge of her vast resources.

In the precious woods of Brazil alone there is an industry capable of enriching a nation. Some author has begun a simple enumeration of the useful woods of Brazil, giving only their names and synonyms in alphabetical order. Thus far he has only progressed through a few of the first letters of the alphabet, and the result is a good-sized volume. So abundant are these hard and fine woods that the difficulty is to find a coarse or soft wood sufficiently easy of being worked to serve for building purposes. I have observed that the valuable portion of most of these precious wood is confined to a small portion of the heart; the sap wood surrounding it being of a very different colour as well as very much softer.

Another peculiarity of these Brazilian species of woods is that they are not gregarious, as ours are. That is to say, we do not find a forest made up largely of one or several species, but all sorts grow together, not more than one or two of a given kind being obtainable in one place. This increase greatly the difficulty and expense of collecting them. Two enterprising firms are said to have established saw mills on the island of Maranhão, in the mouth of the Amazon. From here they send out little tugs to bring in the passing logs, which constitute their only supply.

The fibre plants of Brazil are already attracting a great deal of attention, and I expect they will yet revolutionize the woven fabrics of the world. Their name is legion, and they represent many diverse families, and it can hardly be that among them there are not some equal or superior to any now in use.

The discovery of aniline dyes has ruined the trade in those of the vegetable origin, other-wise the forests of Brazil would have furnished a mine which the workings of centuries would not have sufficed to exhaust. Many times in pressing our botanical collections we would find our papers, and even our clothing, beautifully and permanently dyed by the roots, bark or leaves of the plants that we had collected. Again we would observe a stream or pool deeply tinged by the exudation of some log that had fallen into it.

The food plants of Brazil, if we include those introduced, includes about everything known to tropical countries. Introduced fruits soon run wild. Thus the peanut, the yam and the cocoa, origin of the chocolate, may be found escaped in every direction. The cocoa especially attracted our attention, for we found entire forests of it in some places. Of coffee we find several native species, and wild specimens of the Arabian species are not rarely met with. One of the native species has white seeds, as has also a native species of theobroma. No food plant flourishes more abundantly than the cassava, there called mandioca or yuca. Of this there are several species, one of which occurs wild in the greatest abundance. The plant is in the euphorbia family, near rubber, and produces large sweet potato-like tubers. In its fresh condition it is a deadly poison, but when cooked it furnishes a wholesome food. The best varieties, baked in the ashes, are equal to our best potatoes. From these roots, after they have been macerated almost to the point of putrefaction in order to destroy their poisonous principle, a starchy food, mandioca, is obtained, which answers in Brazil the purposes of bread.

I close my remarks with a brief account of the drugs of this interesting country. Should any genius ever be born capable of writing a complete history of the medicinal plants of Brazil, it would probably constitute the most interesting and important contribution of its class. Indeed, the elaboration of the medical flora of even one of the Brazilian provinces would be the work of a lifetime. Each tribe of aborigines and each community of settlers has its

own native materia medica, and of the virtues of many of these plants there can be little doubt. Aside from these strictly domestic remedies, the region affords to civilization some of its most useful drugs, and every year is adding to the list.

One of the most interesting of these is guarana, the virtues of which as a remedy for migraine are rapidly becoming appreciated. It is the product of the seeds of *Paullinia sorbilis*, a plant quite nearly related to the horse chestnut. There is much false information afloat concerning this drug, and I have taken pleasure in investigating the real facts concerning it. The plant is a woody vine of considerable size, existing naturally in many parts of the Amazon valley. Considerable portion of the drug, however, is the product of the wild plants, it being extensively cultivated in the Maderia region. Under cultivation its appearance is quite changed. Instead of being allowed to climb wildly it is trained to stakes, as the grape in many sections, so that at a distance a plantation bears much resemblance to a vineyard. The white flowers are borne in terminal panicles, and are small and inconspicuous except by being massed together. The fruits begin to ripen in December, as indicated by their bursting open and exposing the seeds, about equal to a hazel nut in size. No time is then lost in gathering the harvest, lest the seeds fall to the ground and become lost. From the outer husks, resembling those of a small hickory nut, the seeds are shelled out with the finger, a very laborious process. The pulp, a white, phlegmy substance, is then washed in the river. The seeds are then most carefully roasted and placed in sacks and beaten to remove the cartilaginous shell. They are then roughly milled in a small hand mill or in a wooden mortar, an exact quantity of water added, and the whole kneaded into a doughy mass. This mass is then moulded by hand into rolls, which are carefully dried by a process requiring several weeks of diligent attention, and are ready for the market. Contrary to the general belief, no adulteration or substitution of any kind is resorted to, these Indians vieing with one another in the manufacture of the best product. The reason that failure has universally attended attempts to manipulate the seeds in this country is that the process requires a great amount of time, patience and experience, which have not been given to it.

The ipecac plant is found on the upper branches of the Maderia. The causes of the present scarcity and high prices are twofold. In the first place the known localities have been largely exhausted, and new explorations have to be undertaken to secure supplies. But another influence of much greater importance is the growth of the rubber industry, which has monopolized the attention of the settlers. Until this interest shall decrease, or until the population of those sections shall become largely increased, steadily cheap supplies of ipecac can scarcely be looked for. It is this fact which gives added interest to my new drug cocillana, which embodies to a great extent the properties of ipecac.

The copaiba tree is one of the handsomest trees of the Brazilian forest. It is not to be classed among the larger trees, yet it often reaches a diameter of five or six feet. Its wood is extremely hard and tough, and is used for various important purposes. A dug-out from this tree often serves as the basis of the strong boats by which the dangerous rapids are navigated. A cross section of the trunk, properly trimmed, constitutes the rude cart wheels of the section. The seeds of the tree when dry resemble bleached bone in colour and hardness, and are used by the savages for making beads.

Very similar to the copaiba tree is the related tree, *Dipteryx odorata*, which yields us tonka beans. With its tall and polished trunk, surmounted by the most dense head of dark and glossy leaves, it constitutes a stately ornament, and during the fruiting season loads the air with the vanilla-like fragrance of its seeds.

The vanilla also grows wild here, and the beans, of poor quality, are sold at 10 cents each.

The jaborandi fringes the river banks, the pariera climbs over the smaller trees, and the sarsaparilla

covers the little elevations. Other drugs exist in rich profusion, but I can only refer to them by name, the strychnos, manaca, stachytarpheta, soliman, barbasco and chamairo.

I confidently expect that in the future, when rational methods of examining and comparing the effects of drugs shall have become more general, many of the drugs now used only by the savages of Brazil will replace the similar agent in use by us.

PADDY CULTIVATION IN SABARAGAMUWA.

With reference to the recent discussion in your columns about paddy cultivation, I can assure you it is a source of trouble from the day the seed paddy is sown till it is secured in the granary in Sabaragamuwa.

(1) The field has to be fenced to keep out cattle and wild animals during the day, the water has to be turned on and off at night, the villager has to watch it for fear of pigs and other animals. (2) When the ears begin to form and come to maturity the cultivator has to go over the whole field every morning with a paddy winnow on the end of a long light pole, the inside of which is plastered over with jak milk, with which he brushes the top of the paddy to catch the insect pest named goyan messa: were the villagers to neglect the abovenamed pest they would get no crop at all, for the little midge-like insect would destroy the whole crop in a week. When the paddy has been out it is usually thrashed by the men who fix a horizontal pole to hold on to whilst they crush the grain from the straw with their feet: why buffaloes are not used as in other districts I don't know, the percentage of light is about $\frac{1}{2}$ in each bushel which is winnowed out in the field if the weather is fine before removing it to the houses. The paddy before being pounded out by the women is again winnowed and found to contain about 4 measures to the bushel of light. The outturn of rice from a bushel of paddy is usually half if it has been boiled and dried to toughen the grain and burst the husk to making it easier for the women and prevent wastage, if green or *patcharisi* is required, which is not boiled and contains much more starchy matter and is usually made into flour for hoppers and sweet cakes, the outturn is less than half as there is much more waste.

The price paid for paddy in Sabaragamuwa when thoroughly well winnowed is from R1 to 1.50 per bushel according to the distance from the cart road, or large town, and the price of village rice from 8c. to 12c. The price paid for converting a bushel of paddy into rice is also from 8c to 12c, but it is usually paid in kind by giving $1\frac{1}{2}$ to 2 measures of rice and the broken leavings.

Village rice is much more satisfying than Coast, but it does not boil out nearly so much, and is therefore considered less economical than Coast rice. When very white village rice is required it is pounded with straw and you would not know it from the best Coast table rice.

There is nearly as much hill paddy grown in Sabaragamuwa as wet—the wet climate being very suitable for hill paddy, but it is not considered so nourishing and is in my opinion less palatable than the water-grown grain.

NEGOMBO CINNAMON AND COCONUT DISTRICT.

Nov. 13th.

Weather very dry: only 2.26 inches of rain since the 17th October. This I fear augurs a dry north-east monsoon. For the last 10 years or so the seasons have been most unreliable. I remember the time when it was possible to have prognosticated the weather ahead with great certainty: now anyone attempting such a thing would fail miserably. The only reliable augurs now are the scientific ones, and we should pay more attention to their predictions than we at present do. The health of the district is pretty good, the mornings and evenings cool and the intervals scorching.

PADDY CULTIVATION: IRON VS. WOODEN PLOUGHS.

I have not the slightest hope that Mr. Green, even if he live to a green old age, will see the use of the iron plough popularized. Living as I do in intimate contact with the *Goyya*, I can feel his pulse pretty accurately. The plough is too heavy and expensive to become popular. I have the prize plough of the Matale Exhibition of 1887. It is an inch wider than the ordinary native plough, and yet my men require compulsion to yoke on my own cattle to it. They always find an excuse to substitute the ordinary plough for it. I may be wrong, but I am strongly of opinion that more is attributed to the beneficial results of using the iron plough than is justly its due. The benefits arising from deep ploughing and from bringing the subsoil to the surface are by no means invariable. They are dependent on the composition of the soil. It is for this reason that the use of the iron plough should not be generally recommended. In very many instances the use of a cultivator or subsoiler will be more advantageous, as for instance on a sandy soil. A native plough works the same as a cultivator, and is the best for use on sandy fields. To say that it merely scratches the surface of the ground is to say what has not received the sanction of truth in spite of its frequent repetition. Anyone acquainted with its working knows that it works deeper than an iron plough can be made to work with one pair of bullocks. Its faults are its lightness and consequent inability to make an impression on a soil that is not thoroughly saturated with moisture, and the waste of labour involved in using an implement with so narrow a furrow.

It may be as well that I should explain why I said that the beneficial effects following the use of the iron plough are exaggerated, or I would raise a nest of hornets about my ears in the persons of Mr. Green's *protéges*, who are extremely loyal both to him and to the plough he has introduced. I think that the increased yield which undoubtedly follows the use of the iron plough is due more to the after treatment of the soil than to its use merely. Anyone acquainted with paddy cultivation, knows that except where no water is available the fields are constantly under water. The soil is never subjected to the beneficial influence of aeration. Being constantly under water it becomes sour, the protoxide of iron which mostly all swampy lands contain, and which is soluble and harmful to vegetation, has very few opportunities of coming in contact with the oxygen of the atmosphere, and becoming insoluble and even beneficial. The decay of the vegetable matter is retarded, and it has very few opportunities of absorbing the ammonia of the atmosphere. According to the system practised by the Agricultural Instructors, the fields are ploughed and aerated for six weeks or two months, and the increased yield of paddy is invariably spoken of as due to the use of the iron plough. I think that if fields are ploughed with the native plough and subjected to the same after-treatment, the results will not fall short of those which follow the use of the iron plough. I hope that in future experiments Agricultural Instructors will plough equal areas with both kinds of plough, subject them to the same treatment and record results. It will be far easier to wean the conservative *Goyya* from the unscientific treatment of his soil than to make him take to heavy and expensive ploughs. Let the beneficial results of aerating his field after ploughing be demonstrated to him, and he will follow it even if the practice results, as it undoubtedly does, in a plentiful crop of weeds and necessitates more frequent cross ploughings to get them under.—Local Examiner.

DRUG EXPORTS: PERU.—The value of coca leaves exported from Peru in 1888 is returned at 369,361 soles, which represents about 730,000 lb., the price ranging locally from 25 to 30 soles per 50 kilos. The exports of the so-called "crude cocaine" are placed at about 100,000 soles.—*Chemist and Druggist.*

CEYLON TOBACCO.—We call attention to the letter sent to us by Mr. Wm J. Roberts of Messrs. A. J. Morgan & Co. of Alexandria on the subject of Ceylon tobacco as an article of export to Egypt. The prices mentioned of 25s to 30s a cwt. (2½ d to 3½ d a lb.) do not look very attractive: but as only the commonest kind of leaf seems to be required, there may be room for some trade.

VANILLA EXPORTS: MAURITIUS.—The following were the exports of vanilla from Mauritius in the years 1886 and 1887, according to value and weights:—

	1886		1887	
	Value Kilos	Value Rupees	Value Kilos	Value Rupees
To France	12,054	208,312	12,496	182,421
To United Kingdom	10,604	100,537	5,964	67,988
To Other Countries	234	3,200	51	530
Total....	22,792	312,049	1,501	250,939

—*Chemist and Druggist.*

NILGIRI TEA.—A correspondent of the *Madras Mail*, writing from Coonoor, asks:—

Will some of our Planters kindly tell us what tea costs per pound to put down in the London Market from the Nilgiris? Mr. Owen of Ceylon, in his work on tea, puts it down at 7d. The Assam Estates put down their cost at from 7d to 1s 1d. I would put the cost for the Nilgiris down at 7d if not much cultivation is done, and at 6d with good cultivation. This ought to be a very interesting question for Planters, and I trust a number will come forward with replies. If tea can be put down in London at 8d per pound, and an average of 1s obtained for the whole produce of a garden, how happy all interested in the Nilgiris would be. Nilgiri tea is beginning to attract some attention in London now. Let us all strive to keep up quality.

CARBOLINEUM AVENARIUS.—Messrs. Stohmann & Treusein of Hamburg have sent us a circular respecting the above patent preparation, composed, it is said, of various septic substances, which, it is affirmed, when applied to wood as paint (the colour being a fine walnut) does not stop up but impregnates the pores and thus preserves even unseasoned wood. Certificates from railway officers in Germany are quoted as to its value when applied to sleepers and other underground woodwork as well as to wooden buildings, rolling stock, &c. There is also a testimonial from South America as to the value of Carbolineum Avenarius in protecting timber from white ants. The claim made for this substance that by merely applying it as a paint it penetrates the pores of wood and acts as an effectual preservative is, if true, very important, because steeping and injecting processes are very expensive. We quote a passage:—

"Two boards cut from one and the same piece of pine, one of which for the sake of experiment was painted with Carbolineum Avenarius, and the other left unpainted, were buried, and after a lapse of three years dug up and examined. The result was that the wood to which the Carbolineum Avenarius has been applied, shewed no signs of decay, whilst the other was found to be in a rotting condition."

This reminds us of an experiment by the late Dr. Elliott, the results of which we saw half a century ago. "Kyanizing" had just been introduced and described in England, and Dr. Elliott tested two pieces of wood as above described and with similar results. Creosoting as now applied to the pine sleepers used on our railways is effectual in arresting decay only for a limited time, and it might be worth the while of our railway authorities making a trial of the carbolineum paint, which seems to be used for sleepers up to timber required in ship-building. Besides its preservative qualities it is said to be a good disinfectant,

CEYLON TOBACCO:
A PRACTICAL PROPOSAL.

Alexandria, Egypt, Oct. 29th.

DEAR SIR,—Being interested in the subject, I read with great attention your useful book on the Cultivation of Tobacco in Ceylon, and would feel obliged if you give publicity to my letter in the columns of the *Observer* for the benefit of the Ceylon tobacco growers.

The importation into Egypt of very low kinds of American tobacco, which realize in bond from £25 to £30 per ton, has increased enormously within the last two years.

Could not therefore the very cheap, dark and strong kinds of Ceylon tobacco compete favorably and eventually take the place of the above to the great advantage of your growers? A light-colored tobacco for coloring purposes would likewise suit our market, and find a ready sale if the price of same is moderate.

If, therefore, any Ceylon tobacco grower feels inclined to communicate with me on the subject, with a view of ultimately entering into business relations, I should require a lb. sample of each kind to be forwarded to me with full particulars respecting the mode of packing, whether in hogshead, bales or otherwise, also approximate weights of each package and the prices delivered in Colombo or f. o. b. Alexandria or Port Said.

Trusting to be soon in receipt of an answer to my proposals from one of your enterprising planters, which will, I hope, lead to mutual satisfactory results, I am, sir, yours faithfully,

W. J. ROBERTS.

PLANTING COFFEE UNDER SHADE;
THE ESTATES IN COORG
AND MYSORE.

Mercara, Coorg, Nov. 1st.

SIR,—On seeing my letter to you in print, in the copy of the *Observer* received, one or two points strike me as requiring explanation and amplification. I should have said, that the estates I mentioned, that were replanted in Mysore, were not abandoned but estates in fair cultivation, with the soil in good condition, and generally shaded. The coffee trees were mostly of the objectionable chick caste, and were 40 years old I dare say (although I gave 30 years as their age) when uprooted. The slopes of the land on which the best estates in Coorg lie are easy, and the forest trees deciduous. The land is of a class called Bambu, that I remember Mr. Donald Stewart saying he would not think of putting a coffee tree into, when he saw my first venture on that class of land, which I was the first planter to break up in those, what looked then, uninviting deciduous forests. Thousands of acres of such land now form the sites of the most productive and most beautiful coffee plantations in Coorg. The bambus, thorns, scrub, and bad caste trees, are felled and burnt, leaving those trees known to be good for coffee, such for example as the black or rose wood (*Dalbergia latifolia*), wild jak (*Artocarpus hirsuta*), good jak (*artocarpus integrifolia*) and other kinds of suitable trees often found mixed up with the objectionable kinds in deciduous forests. Such trees as Benteak (*Lagerstromia microcarpa*) and a tree whose bark yields lime (*Terminalia tomentosa*) and others of a palpably bad kind are felled. The soil in these deciduous forests is mostly black, for 12 to 18 inches down, the deposits of annual fires that have passed through them for ages past is very hard, until broken up, and mixed with the subsoil, by the trenching and renovating pitting which follows the planting, but after being covered with shade, it ceases to cake, and remains comparatively moist through the

dry months. Land covered with evergreen forest is rarely touched now in Coorg. When I came here in 1860 all the estates had been formed upon ground that had originally been covered with evergreen forest, in climates with a rainfall ranging from 120 to as much as 300 inches a year. Very few of these estates are left, they are mostly now *lantana* wastes. Deciduous forest lands had then no value, and in 1861 I found no difficulty in getting a grant free of a block of 2,000 acres, on which the first estates were formed in S. E. Coorg; all that part of Coorg is now a rich garden of shade-covered estates. Not an estate in the open will be found in Coorg or Mysore at this moment, so that Ceylon men will see that opinions are not divided at all as to the imperative necessity of shade for the permanent well-being of coffee plantations in these parts. A further consideration is, shade equalizes crops, inasmuch as it saves expenditure no weeding, on small item in estate upkeep. Smaller crops pay on a shaded estate, as upkeep expenses are smaller. Then there is an element of permanence in an estate under good shade, even if all cultivation ceases, it lapses into forest, not deteriorated, as the soil is protected from the exhausting effects of a tropical sun, and is enriched by deposits, constantly going on, of fertilizing matter. *Shade lopping* is however a work that requires regular attention. The shade requires lifting, so as to regulate light and air. The loppings give their return of manurial deposit. Estates under shade are perennially fertilized by droppings that make vegetable mould. *Cinchona* trees mixed with other shade trees, at good distances, say 30 yards apart, are not thought detrimental to coffee as shade trees by many men.

J. P. HUNT.

CINNAMON CHIPS: THE LIST OF ESTATES
AND GARDENS AGREEING NOT TO MAKE
"CHIPS."

Goluapokuna, Negombo, Nov. 13th.

SIR,—With the sanction and approval of the Committee I am now able to send you a list of estates and garden proprietors who have agreed to give up the scraping of cinnamon chips for two years, and who have signed a document upon honour to that effect. It was, as you are aware, agreed at the general meeting of cinnamon estate owners held in Colombo on the 20th February last, that the scraping of chips should cease from the 1st October; but at a Committee meeting held on the 28th September, it was, on the representation of some of the members, decided to extend the date to the 1st November, as by this concession many more signatures might be expected. The date of the agreement is therefore from 1st November 1889 to 31st October 1891. The acreage represented by the signatures obtained is 9,952, and a few more signatures are promised, which will bring it up to a little over 10,000 acres; and this is about what was hoped for when the movement was set on foot. The return of bark is about three of quill to one of chips; and taking the yield of bark at 100 lb. per acre—75 lb. quill and 25 lb. chips—the proportion of chips from 10,000 acres would be 250,000 lb. This I believe is within the mark; and as the suppression of this quantity of chips is what the promoters of the movement aimed at, I think it may be fairly claimed that their object has been achieved. To insure its complete success it now only remains that the terms of the agreement upon honour shall be faithfully and strictly adhered to, and this I have every confidence will be done. My thanks are due, and hereby acknowledged, to Messrs. Jacob de Mel, J. F. Driberg, S. R. de Fonseka, R. A. Miranda, and J. de S. Rajapak-e Mudaliyar, Shroff of the Negombo Kachcheri, for willing assistance rendered; but specially to the last two gentlemen, without whose cordial and valuable co-operation it would not have been possible to have brought the matter to so satisfactory

a conclusion. To give the name of each estate and its acreage separately would trespass too much upon your valuable space. I therefore only give the owner's name, the number of his estates, and their total acreage:—

DOCUMENT FOR SIGNATURES ON HONOUR.—We the undersigned proprietors and representatives of proprietors of cinnamon estates entered opposite to our respective names, do hereby bind ourselves upon our word of honour on and after the 1st day of November 1889, and for a period of two years following, not to prepare on the said estates, or permit to be prepared by others any cinnamon chips for any purpose whatsoever. Nor to permit the removal in a green state of the chip sticks cut out in the work of pruning, neither to allow the cinnamon leaves of our properties to be used for the distilling of cinnamon leaf oil, on condition that the signatures of estate owners representing at least one half of the chips now exported shall have been obtained:—

WILLIAM JARDINE, Secy. of Committee.

JAPAN TEA BOXES.

Colombo, November 13th.

DEAR SIR,—I enclose an extract from Messrs. Rucker & Bencraft's weekly tea circular dated 24th October with reference to Japan cedar boxes; and as the matter is of much importance to planters you will no doubt find space for the same. Up to the present time I have never heard any complaint of any kind against Japan momi boxes.—Yours faithfully,

E. B. CREASY,

(Extract from I. A. Rucker and Bencraft's Weekly Tea Circular, dated London, Thursday evening, Oct. 24th 1889.)

JAPAN PACKAGES.

We commend the attention of our Ceylon correspondents to a letter in the *Overland Ceylon Observer*, of Sept. 24th, concerning tea packed for the first time for four years in Cedarwood, withdrawn in sale, and afterwards sold at considerably less money, the lower amount bid being on discovery of "taint."

This taint from the wood has increased, and this tea, sold three months ago, is still on the dealer's hands. As the matter is of great importance we quote what we said on June 27th:—

"Take great care that the wood is well seasoned and suitable for tea. Until the lead of a Japan package is cut, or even for a few day after cutting open for inspection the tea will remain all right, but after being

sold for a month or two, if the wood is the least aromatic or cedary, the scent is certain to affect the tea, and then up comes the package from the country buyer with the complaint the tea is unsaleable. The London dealer pockets the loss and says nothing, but becomes prejudiced against what ought to be, and are, if carefully chosen, most useful and well made packages."

THE CULTIVATION AND MANUFACTURE OF THE CASTOR PLANT IN CEYLON.

Colombo, Nov. 16th.

SIR,—The large import of castor oil, referred to by Mr. Le Mesurier in his Administration Report for last year, is made by our good friend Mr. E. B. Creasy, who has since the advent of the mail steamers to Colombo imported monthly large quantities from Coconada. Some native firms in the Pettah also import this oil, and the Customs Annual returns will show the proper quantity. Very little is locally used for machinery &c., and the balance is reshipped for machine use on board steamers.

The castor plant grows almost wild both in chena and the lowlying land almost all over the island, and a small central mill in connection with the Wellewatta big mills would I think be a remunerative concern, where, no doubt, growers (or rather gatherers) of castor seed can send their produce for sale along with the cotton that is shortly expected.—Yours truly,

A. B. C.

The extent of land under tea is steadily increasing. In the Rayigam korale additions were made to the principal estates, and a large acreage of abandoned jungle known as Cargil's land at Ingriya, where tea had not previously been started, was cleared and planted under European superintendence. In the Pasdun korale there was a considerable increase in the acreage under cultivation. About 1,000 acres of tea and coconut have been added to the cultivated area of the District, together with 100 acres of newly asweddumised paddy fields and a similar extent of cinnamon.—*Administration Report for 1889.*

VEYANGODA, 29th June.—Speaking of Coconuts reminds me that the Mills being erected by the taciturn Mr. Millen are fast nearing completion. It is supposed that they will be completed by the end of another week. The building is a long low-roofed one, covered on the top and sides with sheet iron. With more windows in it than the historical Black Hole had, I think the temperature within it with a bright sun blazing overhead will not be exactly at freezing point. I should not wish to be within it during the day. So far the Mills have not affected the price for Coconuts, nor indeed created a demand even for them. Mr. Millen and his Manager are as silent as the sphinx, but outside reports speak of the demand as likely to be at the rate of 40,000 nuts per week. I hope this is true.—Local "Examiner."

CINNAMON CHIPS.—We call attention to Mr. Jardine's letter in another column and beg to congratulate this gentleman and his supporters on the successful attainment of the very practical object they had in view during their recent agitation. The exports of cinnamon chips will be watched with special interest during the present season. For the last ten years, the average shipments of cinnamon chips have been about 500,000 lb. the maximum export of 629,000 lb. having been in season 1884-5. It now remains to be seen whether the falling-off by one-half will be generally realised. If it is, it will show that Mr. Jardine's Syndicate have kept their word of honour—otherwise the export figures must at once show that there has been a breach of compact. However, we trust for the best and that the gentlemen who have signed the agreement will faithfully hold to it.

TOBACCO.

(From the Bulletin of the Jamaica Botanical Department.)

In Bulletins 6 and 8, particulars were given of a prize of Fifty Guineas offered by the London Chamber of Commerce for the best sample of Tobacco of 400 pounds weight grown in the British Colonies. It is now announced that the prize is, by the award of the Judges, divided equally between Jamaica and North Borneo. Messrs. Machado's Tobacco, grown at Temple Hall, in winning the prize will be even more in demand than at present, and it is quite probable that Jamaica Tobacco and Cigars will be sought for in European markets.

It rests with growers and manufacturers of Tobacco in this Island, by scientific cultivation and careful curing to maintain and increase the reputation thus gained; and it is possible for those who now are producing a very inferior kind to take advantage of any increased demand, not by selling worthless Tobacco and ruining the market for all, but by laboriously learning how to improve from the directions given by one who thoroughly understood the whole art. Such directions are given below, drawn up by a worthy Cuban, the late Mr. J. C. Espin, who lived many years in Jamaica, working himself in the fields, and afterwards being engaged in the manufacture of Cigars. This pamphlet, the result of long experience, was promised for us in the Jamaica Bulletin, but on Mr. Espin's appointment to undertake Tobacco culture in Trinidad, he preferred to take his manuscript with him. The Government of Trinidad purchased the copyright, and published the pamphlet as a Botanical Bulletin. By their permission, it is now reproduced in Jamaica, not for those who already understand their business, but to help those who are conscious of a need of improvement.

TOBACCO CULTURE.

By J. C. ESPIN: For many years Planter and Manufacturer in Cuba and Jamaica, and late Government Expert for Trinidad.

PREFACE.

The clear and ordinary language adopted in writing this Guide will, it is believed, be more within the reach of those who most need it than a more elaborate and scientific phraseology. Unacquainted with science, the writer merely explains the methods of growing and curing the Tobacco plant, without entering into its Natural History, Chemistry, etc., which he deems unnecessary in a purely practical Guide like this. The writer confidently recommends the methods here explained as they are based, not on hearsay and "theory," but on his own experience as a planter and manufacturer for many years. He assures those who may adopt this little book as their guide that if strictly followed out, the Tobacco obtained will be of excellent quality, depending, of course, on the physical conditions of the locality where grown.

Much has been written on Tobacco, a plant which forms one of the most important factors of national wealth in the countries where it is largely and efficiently cultivated; but the works on the subjects, which we have had the opportunity of reading, are either so scientific in the language and style as to be beyond the knowledge of the majority, or so diffuse and full of different and even opposite methods as to bewilder the cultivator. There are some works which give directions contrary to our experience, and others again devote more space to the botany, physical and chemical properties of the plant, than to the proper manner of growing and curing it, which latter ought to be the principal aim.

With a view to supply, as far as our knowledge allows, a thoroughly practical and reliable guide, devoid of the defects above mentioned, it was decided to prepare the present Pamphlet, not that it will be, by any means, absolutely free from errors, but it will be one which we earnestly believe will be of real and practical assistance to the beginner, as it was written "in the field" whilst actually growing, curing and manufacturing "the weed" for the market, and therefore after every method had been thoroughly tested. Several manuscript copies of it were given to friends who desired to try the cultivation, and the results of their experiments were most successful.

As the writer is the native of Cuba and the original was written in Spanish, this is necessarily a translation, but it differs in no way from the Spanish in the arrangement, etc., the writer having carefully prepared the English as well as the Spanish, but a foreigner by birth, the writer begs the indulgence of the English-speaking readers towards the correctness or elegance of the English construction, as it is not possible for him always to frame his sentences in a style untainted by his mother tongue, and he begs to be excused for this somewhat lengthy Preface, and leaves to those who might follow this Guide to decide how far he has succeeded in fulfilling his object.

CHAPTER I.

The Tobacco plant was not known in Europe till the discovery of America in the fifteenth century. It is said that Columbus, during his first voyage while off the coast of Cuba, sent some explorers to land and obtain information concerning the natural resources of the country, and that on their way back they, for the first time, witnessed the use of a weed, which the ingenious caprice of man has since converted into a universal luxury. They beheld several of the natives going about with firebrands in their hands and certain dried herbs which they rolled up in a leaf and lighting one end put the other in their mouths and continued inhaling and puffing out the smoke. A roll of this kind they called a "tobacco," a name since transferred to the plant of which the rolls were made.

There are many species of Tobacco, but the Cuban Tobacco plant is one known to Botanists as *Nicotiana Tabacum L.* (Cuban variety), and it is to the cultivation of this kind that we will direct our attention it being the best Tobacco known and the only one I have cultivated. The culture of Tobacco may be divided into five periods, viz., Nursery, Planting, After-cultivation, Curing and Packing, each of which will be treated of in its respective order in the following pages; but first a few words on Climate and Soil.

CLIMATE.

Climate is an important point in the cultivation of Tobacco, but as this cannot be modified by artificial means we should seek a district where the temperature and moisture of the locality is similar to that of Cuba, warm and humid. In a country where the seasons differ from those of that Island the periods of cultivating must be accordingly varied.

SOIL.

The soil as well as the weather effects the plant to a considerable extent, for plants grown under the very same climate, but on slightly different soils, produce Tobaccos altogether distinct in quality. For instance, in Cuba two neighbouring fields, which are of course under the same climatic influences, produce Tobacco which differ in many particulars. Therefore, not only must the seasons be carefully selected, but the soil also requires to be chosen with great care, a light sandy loam, mixed with a fair proportion of vegetable debris, being preferred to any other. Clay lands are very unsuitable. Sandy, loose grained soil, absolutely free from clay, will produce Tobacco of far better quality in every respect than any other kind of soil.

CHAPTER II.—CULTURAL INSTRUCTIONS.

NURSERY.

In the selection of the land for making the Nursery attention must be paid to the existing conditions of the soil, and action taken in accordance therewith. We will therefore describe in a concise manner the most convenient and the best methods of preparing it.

The best soil for making the Nursery is to be found on virgin or untilled land, and it is more easily prepared. On the other hand, in cleared and cultivated land the seedlings grow better and safer, but give more trouble than in virgin soil. Old, abandoned dung-hills, the sides along old wooden fences, hogsties and similar places, are very good soils for making Nurseries on. The nursery may be formed into beds or left level land, as appears most suitable.

1. Virgin land is prepared by cutting down every tree on the portion intended for the Nursery, leaving only a certain number of small trees whose branches

will afford sufficient shade to the tender plants (these will have to be removed later on). The land should be prepared long and narrow and with a North-easterly or South-easterly exposure. The land should now be swept with a broom made of the thin branches of trees or boughs so as to remove away all rubbish, etc., from it. The soil should be slightly hoed, and the rubbish arising from this hoeing swept and thrown away also. The soil is now ready for sowing the seed.

2. On cultivated soil it is preferable to select the plot as level as possible, but if it should be too much on the incline it must be drained by means of trenches dug at the sides of the Nursery to prevent rain water from running into it and carrying away the seed. This should also be done to Nurseries on newly-cleared land. The seedlings will thrive much better if it should be that the land has been used the year previous has a horse or sheep-pen, pig-stie, or dung-hill. The soil is prepared for sowing the seed just the same as on virgin soil.

3. Whether on virgin or on cultivated soil the seed may be sown in BEDS. The method of procedure is as follows:—In the month of May the soil is ploughed, and immediately after it is hoed, and then covered with a layer of vegetable rubbish, such as dry grass, etc. A few days after, when weeds have sprung up, the rubbish is burnt for the purpose of destroying all insects and grubs which infest decaying vegetable matter, and left in this state till weeds again spring up. Another layer of vegetable rubbish is put on and burnt as before, and a couple of days after this last burning the soil is hoed and the beds made. They should be above four feet in breadth and of any desired length, though for convenience in walking through the Nursery they may be made about ten feet in length, the pathways along and across the beds being about half a yard in width. The height of the beds should not be more than ONE INCH above the level, having long wattles placed at the edges or borders of the beds sustained by pegs driven down at their extremities so as to support the earth. Corn is then planted in the middle of the beds, two grains per hole, and each hole two feet apart. Near the time of sowing the seed the soil is chopped with a cutlass without injuring the corn. Corn preserves the moisture of the soil and protects the young plant from the rays of the sun. If when the seedlings spring up the corn has ears, they should be picked off, for they damage the seedlings.

4. A Nursery can be made so as to be at the same time a Tobacco field. It is done as follows:—The land is cleared of trees, the boughs and rubbish burnt and corn immediately planted on the land. Previous to sowing the seed, the earth is chopped and prepared as explained for beds. The seed is sown as usual, but when the plants are fit for transplanting they should be thinned out where two many grow together, and those taken out planted where there are few or none at a regular distance from each other as on a field. The Tobacco grown by this method yields more leaves than by being transplanted to a field, possessing besides the advantage of their being finer in texture and of a better colour. The after-cultivation and curing is identical to that planted otherwise. The Cuban planter calls the Tobacco so grown "*Criollo*" (Creole). This is generally done in the Nurseries after planting in the field is finished, but is never adopted as a regular system of culture, because there is no uniformity in the quality of the leaf and the quantity produced per acre.

THE SEED.

1. Among the most important points in Tobacco culture is the selection of the seed. It should be taken off the most healthy and perfect plants, and when properly ripe, that is, when the seedpod blacken. The plants selected for seed should be left uncut and should not of course be "topped," and all suckers plucked off. The seedpods on their stalks should be thoroughly dried and then hung up in bundles for some length of time. It is preferable to rub out the seeds of the pods, winnow and put it to well-covered demijohns, jars, or glass bottles. The seeds sown the first year ought to be imported directly from Havana as the

only means of securing the Cuban kind of Tobacco. Frequent supplies of seeds should be regularly supplied as it is apt to deteriorate if grown too long in one district.

METHOD OF SOWING THE SEEDS.

Care must be observed in sowing the seeds that they are evenly scattered on the soil, for if they be thickly sown the young plants will spring up too closely and will be so delicate and tender that they will not stand transplanting. To secure the seeds being evenly scattered they should be mixed with dry fire earth or sand. If when the seed is sown it does not rain the soil must be moistened with a fine-rosed watering-pot, raising the hand as high as possible so that the water may bury the seeds, being careful at the same time that the water does not wash away or throw the seeds together. The seed should be sown a month and a half before the seedlings are required for planting, for at the end of this time they should be fit for transplanting. The proper sowing season is from the middle of August up to the beginning of October, on such a day as it is likely to rain. Should it not rain the soil must be watered as before explained.

CARE OF THE NURSERY.

When the leaves of the seedlings are about the size of a sixpenny piece or a shilling piece, the corn and branches of the trees left must gradually be cut away so that the young plant may become gradually accustomed to the heat of the sun, preventing by this means the risk of their perishing when transplanted.

The Nursery must be frequently weeded to prevent exhaustion of the soil and weakening the seedlings. The weeds must be rooted up with the hands, being careful not to injure the seedlings. Whenever the Nursery is weeded or seedlings have been removed for transplantation fresh seeds should be sown in order to always have a supply of seedlings. According as the shade is taken away the supply of water to the seedling should be, in like manner, diminished. If insects be noticed in the Nursery, it should be slightly watered with lime water, sufficiently diluted so as not to burn the seedlings, and the larger grubs destroyed every morning by hand. The seedlings, to be fit for transplanting must have six leaves, and these leaves of the size of a half dollar piece. Before rooting up the seedlings for transplanting, if no rain occurs, the ground should be properly wetted to facilitate their extraction with all their roots. They should be slightly shaken to remove some of the earth attached to their roots. In taking out seedlings for transplanting the fingers should be carefully put down to the root in order to avoid breaking the stalk.

CHAPTER III.—PLANTING AND PREPARATION OF THE LAND FOR PLANTING.

The proper month for planting is September, but if inundation of the land be expected, planting should commence in November.

We have noticed in various works on Tobacco Culture that artificial manures are highly recommended. We believe that by this means the Tobacco can be made to yield larger leaves, according to the quality of the artificial manure, but it can never be obtained possessing the aroma and other qualities essential to Smoking Tobacco. The only application admissible is that of lime, which SHOULD ONLY BE USED when the soil is very much exhausted. In the Island of Cuba, the Smoking Tobacco produced is doubtless without a rival in the world, and there manuring with artificial manures is never practised, as the experience of the *Vuelta-abajo* planters a few years since proves clearly the disadvantages attending such usage. It should be remarked that the manure used was Peruvian Guano. The crop obtained during that short period suffered greatly in its quantity and quality, so much so that the planters of *Vuelta-abajo* have given up altogether manuring with such foreign matters. The best method of preparing the soil for planting is the following, which is that employed in Cuba, the manure used being purely vegetable, with the exception indicated, viz., lime.

No other animals but hogs should be allowed to feed on the land intended for planting from the month of May. Weeds and shrubs are allowed to grow freely till July, when it is ploughed lengthwise and crosswise with all the bush. Fifteen or twenty days after, about which time the weeds, etc., ought to be thoroughly rotten, the land should be frequently ploughed, with a few day's interval between each ploughing, if the soil be not too wet, so that by the month of September it shall have been ploughed about eight or ten times and the whole of the vegetable rubbish be perfectly rotten. All the sticks, roots of small trees which have not rotted should be picked up and thrown away and the land raked if not wet. It is convenient to have hogs feeding on the land during this time, as they help to mix up the soil. It is unnecessary to say that when about to begin planting they should be kept out of the field, for they would destroy the Tobacco plants. When there is no fear of floods and planting time has arrived, if there be any weeds growing on the land, it should be ploughed, attaching this time to the plough a log, about four feet in length, in such a manner as to break up the lumps of earth and at the same time collect the rubbish.

To Plant.—The land is ploughed in a direction from North to South, leaving at least a yard between each furrow, but if the soil be very fertile four feet should be left. The seedlings, after being up-rooted as before mentioned, are distributed along the furrows at a distance of eighteen inches from each other. Planting should be commenced *not earlier than three o'clock* in the afternoon on sunny days, but on a cloudy light showery day, planting may be carried on the whole day. Planting may also be begun before daybreak, so that the planting be finished by eight o'clock in the morning. The seedling is held with the left hand and the earth taken out of the hole with the right, and placing the seedling into the hole, throw some earth on the roots and slightly press it down, being very careful not to injure the tender stem of the seedling, and then fill up the hole with the loose soil. The depth at which the seedlings should be placed in the holes depends on its size, for which reason no exact rule can be given, but generally speaking, in ordinary size seedlings the root and a small portion of the stem only should be buried. Tall seedlings can be placed a few inches deeper, according to the size, but in no case should any seedlings be buried so deeply that the lower leaves touch the earth. One should also be careful not to ALLOW ANY EARTH TO FALL ON THE TOP OF THE YOUNG PLANT. Wet weather is most suitable for planting, and if the soil be very wet, the seedlings should be planted lightly, that is, avoiding all pressure on their roots. If the planting be done in furrows, the seedling should be placed on that side of the furrow called by the *vegueros* "oreja," which is the side on the west.

Seedlings from a distance.—When on any account planting has to be done with seedlings brought from a far distance, the greatest care should be observed in transporting and preserving them, for otherwise many will die when transplanted. The best manner is to take out the seedlings early in the morning and place them on the river bank (if there be any near) and under the shade of a tree so as to keep them altogether out of reach of the rays of the sun. After six in the evening of the same day or before dawn of the next they should be put up in small bundles, and before starting for their destination they should be sprinkled with cold water. As soon as they arrive at their destination they should be placed in the cool, under the shade of a tree. Every bundle should be undone and the seedlings separated widely apart and water again sprinkled on all so that when planting time arrives they are quite cool. If planted whilst warm very few seedlings will live.

If there is no rain when planting begins and the soil is very dry, sufficient water must be poured into each hole and, planting ought not to be performed till the following day, when the soil is moist. The newly-planted seedlings should be watered twice daily, before sun-rise and after sunset, for two or more days successively until it is seen that they have taken root. After the young plants are transplanted in the field those

which have died must be replaced, and the operation repeated if necessary to insure a good crop.

Planting on Virgin Land.—For planting no trees or shade of any kind should be used, and therefore every one should be taken away on the land intended for a Tobacco field. Newly cleared land cannot be ploughed on account of the stumps and roots of the trees cut down. The roots could, of course, be dug out, but the expense attending this operation would be great. They may, however, be gradually dug out until in a few years none be left on the land.

When the soil suited for planting has been newly cleared and cannot for the reasons given be ploughed, *HOLING* must be adopted, which is done by means of a pointed pole or an iron implement made in the shape of a lance. After driving the instrument used with some force into the soil, turn it in several directions so as to break up the earth thoroughly, keeping a distance of EIGHTEEN INCHES from each hole and three feet from each row of holes. To give a regular and symmetrical appearance to the field we use a long, strong, single cord with pieces of coloured rags, or any other material fastened in at the distance apart which has been mentioned, namely, eighteen inches. The cord is kept stretched out by means of a stake driven in the ground at each end of the cord. In forming the rows of holes with this line the stakes tied at the end of it are placed at a distance of three feet from the preceding row.

CHAPTER IV.—AFTER CULTIVATION.

About eight or ten days after planting, if the soil is not too wet, the furrows are closed up by hoeing up the earth carefully around the plants and again performing the same operation at intervals of about fifteen days. This operation should be done if it does not rain. As a general rule it may be said that this operation of hoeing, or as it is commonly called, "MOULDING" should be performed as often as necessary to keep the soil loose and free from weeds. Moulding exerts a beneficial effect on Tobacco, aiding its growth and proper development nearly the same as rain does.

When the plants are still young two little narrow leaves (called "*barbas*" in Cuba) appear at the junction of the stem with the two lowest leaves, and they must be picked off as soon as they become visible, for if left they develop into long, narrow leaves, which greatly injure the plant. A process called "pruning" consists in taking off the two lower leaves of each plant as soon as they ripen. Care must be taken not to strip a piece of the bark of the stalk when removing them. When cured they produce a fairly good Smoking Tobacco. Particular care must at all times be taken to keep the plants free from grubs or caterpillars, and for this purpose hand-picking should be done at least twice daily, otherwise many of the best leaves will be perforated and rendered useless for wrapping purposes.

TOPPING (desbotonar).—The Tobacco plant grows more or less high, according to the fertility of the soil and the state of the weather during its growth. "TOPPING" is an operation which consists in plucking off the shoot button or bud (which encloses the flower), at the top of the plant. It should be taken off with the finger and thumb as being the safest way. The time when it should be plucked off is when the two little leaves which enclose the bud open out. Not more than *twelve leaves* should be allowed to remain on each plant, and the surplus leaves should be taken off along with the bud from the top of the plant. One must be very careful not to allow too much time to elapse and the flower to make its appearance, for then the leaves of the plants will be small in size and of an inferior quality. Eight days, or thereabout, after the "button" or bud has been removed, the suckers begin to appear, every one of which should be removed as soon as seen, and the operation must be performed as frequently as necessary in order that the plants may grow strong and vigorous. This operation is called ("*desbijjaar*") *SUCKERING*, the suckers being all those leaves which spring up at the junction of the stem and the leaves of the plant, as well as those that

grow from the root and lower part of the stem. After the third suckering the plants will be fit for cutting, but this should never be done until the leaves are MATURED so as to obtain the Tobacco of prime colour being careful at the same time to avoid their being too ripe, for if this should happen they get discoloured, or dappled, thus losing in quality and producing much "FUMA (that is, almost valueless Tobacco). The leaf is MATURED when on its surface are formed ELEVATIONS or BLISTERS, called by Cuban planters "*vejigar*" BLISTERING, and when the tops of the leaves, held in the hand, sound as if they cracked. It is then that the leaf is fully developed. When the plant has been cut suckers spring up. The leaves developed from these are called "CAPADURAS" or "CAPONES" and to obtain a good Tobacco from them not more than TWO SUCKERS must be allowed to grow from each parent-root, according to its strength, and leaving only those which spring up from *below the surface of the earth* and furthest from the cut stalk. The suckers or "ratoons" should be carefully weeded, avoiding throwing the earth on the cut stem or on the suckers, and moulding should be performed as frequently as the weather and the vigor of the parent-root requires it.

The after-cultivation and curing of these suckers is identical with that of the first crop of Tobacco. "Ratoons" or suckers are developed as many as five times in succession, provided the weather be rainy and the number of suckers left be proportionate to the vigor of the parent-root. The Tobacco obtained each time will be of good size and quality, and sometimes, in every respect, superior to the first cut.

CHAPTER V.—HARVESTING.

When the plant is properly ripe and fit for harvesting, cutting must not be commenced until the dew has disappeared and the leaves are thoroughly dry, that is, after ten o'clock in the morning and continued till about three o'clock in the afternoon. The best knife for use is the hook-nosed pruning knife.

The leaves are best cut in pairs "*mancuernas*," commencing from above and proceeding downwards to a level with the earth, in preference to the method of cutting down the whole plant. The "*mancuernas*" should be placed on poles (of convenient length and thickness, first stripped of their bark) as quickly as possible to prevent the sun from burning the leaves while in the ground, for if this should happen the Tobacco would be greatly damaged. Each "CORTADOR" or CUTTER should have as many COLLECTORS as may be found necessary in order that the Tobacco cut may be on the ground the least possible time. The CUTTERS should throw the "CAPA" or *wrappers* (the best Tobacco) on the space or wall between the rows of plants which they may be following and the "TRIPA" or *fillers* in the next, thus keeping the two classes separate, and for a like reason each pole should be filled with the same class, and when full of the Tobacco should be kept separate in the House. When on the poles the Tobacco should be kept for a while in the sun to wither and then taken to the House; for while it is beneficial to dry in the sun when on the poles, it is destructive to the quality of the leaves if it is dried by the sun while lying on the ground.

If it be decided to cut the plant whole, as is sometimes practised, cutting always commencing at the proper time of the day, each CARRIER should be provided with bands eighteen inches in width and of any desired length. With these bands the cut plants are carefully tied into bundles or "MATULES," so as not to break the leaves, and should be of a size which the men employed as carriers can readily carry. Instead of bands, bags may be used to carry the cut Tobacco to the Tobacco-house. Every endeavour ought to be used not to allow the Tobacco to remain on the ground longer than is absolutely necessary to pick it up, to avoid the inevitable burning which will occur if left long on the ground. The bundles or bag-fulls may be carried to the House either on head, small carts, or any other manner.

The manner of curing the Tobacco cut in these two ways will be described in another Chapter.

Before detailing the CURING, which has to be done in

the House, it is convenient to give a brief sketch of a TOBACCO-HOUSE, and at the same time of the "PILON" or "PRENSA," the "BULKING-BOX" or "PRESS."

CHAPTER VI.—CURING.

TOBACCO-HOUSE AND PRESS.

It is understood that the House must be finished by the time cutting is to commence. The "PILON" or Press is to be made when the Tobacco is dry on the poles and nearly ready for bulking or fermenting in the Press.

THE TOBACCO-HOUSE.

The house should run from North to South (one end looking North and the other South). Of whatever length it is built, TAKE HALF THE LENGTH, LESS ONE PART for the breadth, and with these dimensions well-shaped house will be constructed. TWO-THIRDS THE BREADTH is taken for the LENGTH OF THE RAFTERS, and if the H use be thatched, one foot more should be added to the length, so as to have a greater inclination of the roof to throw off the rain water rapidly. For example, a house of 20 yards in length (the posts supporting the roof being 4 yards high), the breadth will be 9 yards and the length of the rafters 6 yards: half of 20=10, less 1 yard=9 yards, and two-thirds of 9 yards = 6 yards. A house of these dimensions is to be divided into sections, "APOSENTOS," allowing a space of 27 inches between each section so that a man may easily get in to put up or bring down the poles. The same space left between each section (27 inches) should be left at both ends of the house to afford the same facility. A passage one yard in width should be left, dividing the house lengthwise into halves, and each half will have by this passage four sections on each side, thus making in all eight sections, and each of these sections will have four square yards. The apartments are framed by post.

The poles for a house of the foregoing dimensions must be at least thirteen feet in length.

The poles filled with the Tobacco are placed on what are called in Cuba "BARRERAS," which are stout, strong rails, of the length of the sections, nailed horizontally on posts, which form the sections one above the other and at a convenient distance, namely, ONE YARD, so that the tips of the leaves of the upper poles do not touch the but ends of the lower. The space above the tie-beam is divided in the same manner as was done below it. To be able to do the division above as below, it is necessary to put two *tie-beams* and two *cross beams* or *cross pieces* to form each space, and by these the spaces separating each apartment below will be continued above. We would advise the beginner to see a house built by an Expert as the best means of becoming acquainted with its construction.

When the house is singled or thatched, a kind of window or ventilator should be left at the top of each gable so that the air may refresh the Tobacco which is at the upper part of the house. In a foggy locality the sides of the house should also be covered with thatch. Several doors should be made so that after the fog has disappeared they may be opened and air allowed to circulate freely through the house. The sides of the house should be WATTLED.

THE PRESS OR "PILON."

The Press is made in one of the sections of the Tobacco-house, and of the required size. The section in which the Press is constructed must be well closed to exclude the outer air. Long logs are placed parallel to, a little apart from, each other, and on these a kind of floor is made of either boards or wattles, at a height of about one foot. The floor so formed is covered with thatch or dry plantain leaves, and the Tobacco can now be placed in it.

CONDITIONING OR FERMENTATION.

1. MANCUERNAS, or pairs of leaves.

As soon as the poles are carried to the House filled with the Tobacco, cut and arranged as before described, they are placed on the horizontal rails or "BARRERAS," closely packed together. They are left in this state for three days, if it be in the months

of October, November or December, but in any of the following months they must be kept so packed for not more than one or two days.

When the leaves become yellow they are said to be ripe and then the poles must be separated a foot from each other.

There are two methods of treating the Tobacco when in this conditions:—

Method A.—Allow the poles to remain the foot apart till the stalks and the midribs or middle-vein of the leaves get dry, then carry up the poles to the upper "barrederas" and again pack closely, if there be want of room, but if room be not needed, then they may be put a foot apart.

Method B.—Separate the leaves which may be sticking together and place the poles filled with the Tobacco out in the sun for three days, being very careful not to allow rain to wet the Tobacco, and replace them in the house every day at about 2 or 4 o'clock in the afternoon to avoid the dew. Horizontal bars of a kind similar to those used in a gymnasium are made on which to place the poles filled with the Tobacco. At the end of three days the poles are placed on the upper "barrederas," and there allowed to dry properly. The poles may be closely packed if room be needed, but this should never be done unless the "middle vein" or midrib be thoroughly dry.

I prefer this method to the former, because there is no fear of "Sahorno" (putrid fermentation), and the Tobacco acquires a better colour.

Considering the advantages of this method, it is almost superfluous to advise the adoption of it in preference to the former.

2. *When the method is adopted of cutting the whole Plant.*—The bundles or "matules," when brought in from the field, are unloaded at the House, and should be opened out at once and the Tobacco scattered about as widely as possible to allow it to cool to prevent its sweating. When cool and there is no risk of sweating, the stalks of two plants are tied together at the root end with any kind of string, fastening four stems to one string, which should be just long enough to allow the Tobacco to be hung up on the pole, like the "mancuernas." In case the Tobacco plants be rather large, instead of two, only one should be tied at each end. The string should be tied below the upper leaf, on the butt of the stalk, so as to prevent their falling down. One must be very careful to see that the labourers tying do not put more than four small plants or two large ones in each string.

After being placed on the poles the Tobacco cut in this manner is treated just the same as the cut in pairs of leaves, or "mancuernas." Although we have attempted here to describe one of the most important operations, yet it is a fact that scarcely any one can become efficient in the practical part unless he assists in carrying out the work for some time under the instruction of an Expert.

METHOD OF BULKING IN PRESS (EMPILONAR).

Method 1.—At the beginning of Spring, when the Tobacco becomes soft and pliant on account of the humidity of the weather, the poles are taken down—the time for which must also be regulated by the condition of the leaf—the leaves are stripped off, or removed from the stalks and made into bundles or "matules," 18 inches in length by 18 inches in depth, the breadth being the length of the leaves. The leaves are placed with all their butt ends together and properly tied to form the "matu." The "matules" are more easily formed by means of two pairs of short stakes driven in the ground in the House, at the proper distance, viz., 18 inches, strings to be used for tying up the bundles are passed between each pair of stakes. The stakes in each pair being driven apart at a distance according to the length of the leaves. After the bundles are made they are put in the *plon* or press tightly packed together covering them up with thatch or dried plantain leaves

putting on top of all a few blocks of wood, or any other weight, to press the Tobacco slightly. It should now be allowed to remain in the press for at least eight days before commencing the sorting of the leaves, but it is preferable to allow the Tobacco to remain in the press for about thirty days or more, as the Tobacco is benefited by the press, and there is no risk in its remaining here for any length of time, provided the leaves as well as their midribs be thoroughly dry when put into the press. The weights should be removed after thirty days.

When about to sort the leaves as many bundles as can be worked up in a day are taken out of the press, opened out, and the tips and the butt ends of the leaves are moistened with a wet sponge. The bundles are again made up and placed into the press, covering them as before. Twenty-four hours after, when the leaves will have just enough moisture to be handled without breaking, the bundles are taken out as fast as the leaves are sorted.

SORTING, classification or choosing of the leaves, is done to separate the different kinds of leaves according to their qualities, etc. Each planter may classify or sort his tobacco as he thinks best, but the simplest classification is: into *first class CABA* (wrapper); *second class CABA*, *first class tripa* (filler); *second class tripa* and *third class tripa*, the remainder being "FUNK," or inferior Tobacco. The leaves which have been sorted should be immediately, or rather simultaneously, made into hands or "manillas." A "hand," "gavilla" or "manilla" is made by placing the butt ends of the leaves evenly together until the hand is full of leaves, selecting a leaf which is not very sound, twist it like a rope, and wrap it around the butt ends of the leaves so as to tie them properly together, then divide the whole bunch of leaves with the hand and draw the tying-leaf through and close the bunch, thus securing the leaves, afterwards place the HANDS in the press again.

I am greatly in favour of the foregoing method of bulking on account of the many advantages it possesses over the following, which is by some adopted as the usual method of curing at this stage:—

Method 2.—If for want of room in the House or on account of very wet weather the Tobacco becomes mouldy and there be fear of losing it, it should be put into the press at once. In such a case it should remain in the press not longer than is absolutely necessary for stripping off the stalks and sorting the leaves, never beyond eight days, as the dampness of the stalks spoils the leaves. The after-treatment is the same as the first method.

CHAPTER VII.—PACKING AND BALING:

As soon as it is desired to pack the Tobacco the wash is prepared with which to sprinkle it. The "manilla" is held in the left hand, and with the right the wash (betun) is sprinkled on evenly, and the hand of Tobacco well shaken to remove drops of wash on the leaves, they are then put aside in a heap and allowed to remain so for a couple of hours, or until the leaves be sufficiently pliant and soft to permit handling without breaking, and they are again put back into the press. After remaining in the press for about four or six days the hands of manillas are taken out and shaken and made into bunches of three or four hands each, called "manojos," and then put into bales. When baled, the Tobacco undergoes its last fermentation, being ready at the same time for the market, and the curing of the crop is at an end. The *yaguas* which are strips of palm bark used in baling, must be properly dry and pliant and evenly flattened by pressure. Each bale should hold eighty-one *manojos*. The bales are made in a wooden frame, which is constructed on different patterns. It is useless to describe the process, as no description whatever can teach the manner of making a bale. It must be learnt by practice as many of the other processes also must be. After the bales are made they should be put out in the sun till the *yaguas* and ropes with which the bales are tied be

thoroughly dry. After drying they should be stored away in a suitable dry place having a wooden floor.

When more than three bales are put together, one on the other, the pressure of such a weight takes away the softness and elasticity of the leaf, but on the other hand renders it a better Smoking Tobacco. Every one, therefore is at liberty in this particular to use his discretion to suit his interest.

Besides *yaguas* cases are used for packing Tobacco, those made of cedar-boards being preferable, but packing in *yaguas* or baling is by far the best. Such is the prevailed opinion amongst planters in Cuba that it is a common saying there, that "God made the *Yagua* for the Tobacco" (Dios hizo la *yagua* par el tabaco.)

APPENDIX.

(a.) A Nursery 110 yards long and 22 yards wide will grow a sufficient number of healthy seedlings to plant a field of 10 acres.

(b.) For a Nursery of the foregoing size about two pounds of good, healthy seed should be sown, and if these do not grow, fresh seed must be sown again.

(c.) On an acre of land 10,000 plants can be cultivated, but the exact number is 9,680 plants. One man should not attend to more than the number of plants which can be grown on an acre of land.

(d.) The number of plants that will give a quintal (100 lb) of Tobacco cannot be exactly estimated, for it depends on the state of the weather and the fertility of the soil. But in general terms it may be said that if the soil is good and the weather is favourable 1,000 or 1,500 plants will give a quintal.

(e.) Should it rain whilst cutting is going on, the operation must be discontinued until the weather is again fine—as the leaf must on no account be cut while wet.

Tobacco should not be cut during rainy weather, as at that time the suckers are growing freely and take away the quality of the leaf, which is in a measure regained by succeeding dry weather.

BETUN OR WASH.

Take 5 lb. of old, strong Tobacco stalks and put into 2 or 2½ gallons of water, and boil sufficiently to reduce the quantity of water to about one-third so as to obtain a strong, well boiled infusion. The vessel in which this infusion is made should be new and perfectly free from grease. Take a clean barrel, fill with clear water, and put into it a sufficient quantity of Tobacco-stalks, three quarters of which should be of the former crop and one-fourth of the last. Allow it to ferment for four days, and on the fifth day, when it should be used, add as much of the infusion to this as will darken it, and it may now be used.

CINCHONA HISTORY.

The idea of acclimatising cinchona in the British West Indian islands was conceived about thirty years ago, when the exploring party who had been sent to South America to obtain cinchona plants and seed for British India were instructed to send any surplus they might have to the governors of Jamaica and Trinidad for experimenting purposes. In 1861, the year following the receipt of the seed, there were already four hundred plants ready for planting out in the Jamaica botanical gardens. As the climate of Bath Gardens, where the first experiment was made, was unsuitable for the successful growth of cinchonas, they were tried at Cold Spring Coffee Plantation, at an elevation of 4,000 feet. There the climate and soil proved all that could be desired, and in November, 1862, a plant of *Succirubra* cinchona had attained to the height of 44 inches, with leaves measuring 13½ inches long by 8½ inches broad. The same plant, when two years old, measured 6 feet in height, with ten branches, having a circumference of stem at base of 4½ inches.

The experience gained in these preliminary attempts paved the way for the larger enterprise undertaken by the Jamaica Government in 1868, from which date cinchona planting in the island took a fresh departure.

A further supply of seed, consisting of *C. officinalis* and *C. calisaya*, was obtained from Ceylon. In 1886 the Government cinchona plantations in the Blue Mountain district occupied 143 acres. For the purpose of encouraging the cultivation of cinchona by private enterprise, the Government plantations during the last few years have distributed 1,250 oz. of cinchona seed, 1,200,000 cinchona seedlings, and 469,000 cinchona plants.

Large shipments of cinchona bark were made from the Government plantations during the year 1879 to 1884, and the prices realised proved that the climate and soil of Jamaica were particularly well suited to the successful cultivation of cinchona plants. As much as 10s. per lb. was obtained for root bark of *C. officinalis*, while on large shipments the average price realised was 6s. 7d. per lb. All the various species of cinchona have been introduced to Jamaica, including the valuable *C. Ledgeriana*.

About 2,600 acres have been taken up by private planters for the cultivation of cinchona in Jamaica and the industry there is now well established. But as Jamaica was late in the field, and only now produces bark of sufficient age to be placed in the market, the planters are compelled to hold back their bark until there is such an improvement in the market as will justify regular shipments. This, it is hoped, will only be a question of time. Meanwhile, two samples of Jamaica Loxa bark, from trees six years old, grown on a private plantation at 5,000 feet, have been lately analysed by Mr. David Howard and found to contain:—

	Quinine	Cinchonidine	Cinchonine	Amorphous
1.	2.23 p. c.	0.44 p. c.	0.04 p. c.	0.51 p. c.
2.	1.74 "	0.57 "	0.06 "	0.55 "

In each case there was a trace of quinidine.

The tests are thus very much what Loxa bark of similar appearance from South America would give. It is rather a *Chaguera* than a *Crispa* or *Uritusinga*, which gives the richer yields that characterise the finest officinalis from the *Dodabetta* plantations. The fine old South American *HO Loxa* quills, which would now be worth in London from 2s. 2d. to 2s. 6d. per lb., are used by French pharmacists for flavouring liqueurs. They are said to give to the latter a bouquet which cannot be obtained with any other variety of bark, or even with *Loxa* itself when grown in India, Java or Jamaica. For this season only the genuine South American *Loxa* realises prices wholly out of proportion to its alkaloidal value. It is also said that common hard *pitayo* bark at 2d. to 3d. per lb. is used in Spain for giving a "body" to sherry wine.—*Chemist and Druggist*.

AN ITALIAN ENGINEER has experimented with sugar as a means of preventing the incrustation of boilers, with satisfactory results. A boiler which used to be incrustated in six weeks had two kilogrammes of sugar introduced every week for four months, and then a film of incrustation was found which could be easily washed off.—*American Cultivator*.

A RECENT reliable writer says he has destroyed weeds in lawns by dropping crude carbonic acid right into the hearts of the plants. Roots of dandelions dug up a week after the crows were dressed with acid were found to be killed right down to the tips, a foot below the surface. It is not sufficient to merely kill the leaves of the plants; the acids must enter the hearts quite in the centre. Carbolic acid is poisonous, and should not be allowed to come in contact with the skin.—*Ibid*.

WASTE OF MANURE BY RAINS.—Prof. Roberts tells one side of the story in the statement that on an average one ton of water passing through barnyard manure takes away sixty cents of fertilizing material. But if not kept somewhat moist, rich barnyard manure will waste even more by such violent fermentation that it burns away all its ammonia and leaves only the ash. In piled-up heaps of manure in Summer there is usually more danger of waste by burning than by washing. Do not put manure under the eaves, but leave it exposed, if you wish cover with a layer of earth, and the loss will not be serious.—*Ibid*.

INDIA AND CEYLON TEA.

It is difficult to over estimate the importance of India as a source of tea supply. Twenty years ago it furnished 10,500,000 pounds, but so rapidly has the culture of the tea plant increased that the crop for 1889 is estimated at 105,000,000 pounds. The Ceylon district is also a very important factor by reason of rapid development of the tea industry on that rich little island. In 1873 it produced twenty-three pounds, but this year it is estimated that the supply will reach 40,000,000 pounds.

We are indebted to R. M. Holborn & Sons, of Mincing Lane, London, for a map showing the great tea-growing districts of India and Ceylon, which districts are widely scattered. The largest, the Assam district is situated in the northeast portion of India and on the northwestern boundary of Burmah. There are scattered gardens on the northwestern boundary of Nepal and in the Punjab. Central India seems to be entirely devoid of tea gardens, but there are scattered plantations at the southwestern portion of the peninsula at Wynaad and Neilgherries and also in Travancore. The tea district of Ceylon is very compact with Kandy its centre. It extends well into the Southern province and touches the coast in the Western province.—*American Grocer*, Oct. 2nd.

LONDON TEA LETTER.

The Sadiya Roads latest Company has distinguished itself by heading a long "Honour list," with a good "break" at 3s 3d per lb. At one day, the sapient Broker held a maxim that the Sadiya Road's soil, &c. &c., could never produce high class teas? How now? This break, by the way, should be a good advertisement for the Metal Tea Chests. On the whole, considering that over 49,000 packages of Indian and Ceylon teas have been printed this week, there is good ground for congratulation in the way in which the market has stood the strain. Mr. S. C. Davidson has brought out an admirably got up little pamphlet, upon "Sirocco" Tea, for distribution to the Customers of his firm. In this little pamphlet of only twelve pages the History and Manufacture of Indian Tea are succinctly dealt with, and the various processes are illustrated, on every page, showing up at last the cleanliness of the Indian system and machinery as compared with the dirty primitive processes still practised in China. It is written in a light sketchy way which will be really interesting to the general public—and must make a lasting impression, favourable to Indian tea, as compared with China tea, in the minds of the readers. It is just what has been long wanted in its particular way, and the only pity is that its use for distribution is confined to one firm, as, had it been brought under the generic heading "Indian Tea" by the I. T. D. A., for free distribution, by all interested in Indian tea, (obtainable from the Society at so much a gross for distribution), it would have made a capital tract for the purpose. I have shown the tract to several people, who may be taken as fair samples of the general and uninitiated public; in each case the comments upon the page illustrating the repulsive Chinese system of feet and hand-rolling have amply testified to the value which this feature in the tract will have in creating a comparison between India and China tea, which comparison will be lastingly "odious" to the supporters of the latter. Why has this immensely powerful illustration not been made more and long ere this? The illustration should be enlarged to "poster" size, and stuck up in every shop making a speciality of Indian teas. It would reduce China tea consumption in six months, more than 10 years of ordinary competition. Only the figures should be of Chinese, not Indian coolies.—*Indian Planters' Gazette*, Nov. 5th.

COFFEE NOTES.

A Casa Branca planter writing to the *Diario Popular* of S. Paulo, under date of the 6th inst. says that the coffee plantations of that locality, "which were presenting a very encouraging appearance," were considerably injured by the heavy frost which appeared two days before. In his opinion this frost will prejudice the next crop.

The *Diario da Manhã* of Santos under date of the 10th inst. has the following communication from a most respectable firm of that city: "As to the late frosts we may state that we have obtained trust worthy information from S. Carlos, Jahu, Dois Corregos, Pirassununga, Descalvado, Limeira, Rio Claro, Araras Louveira, etc., wherein it is stated that as to the frosts, although heavy, they had not happily produced the expected damage; in any case a good part of the August bloom is lost and for this the winds and cold sufficed, independent of the frost. It is impossible to guarantee that the crop will be completely lost for we have still all the month of September and October for the blossoming of the coffee orchards, and it may be noted that the flowerings of these two months are always the best and are the preferred of the planters. If the orchards have not suffered greatly the crop may be reduced but never completely lost, further advices we have received agreeing with this latter hypothesis. If the cold does not continue the orchards that slightly suffered may recuperate by October and produce a better blossom, the frost even serving as a benefit, as always happens when it is only sight."—*Rio News*, Sept. 16th.

SHIPMENTS OF SUMATRA TOBACCO DURING 1888.

The tobacco was shipped by steamers of the Ocean Steamship Company and the North-German Lloyd, the latter company having in its service the steamer "Schwalbe" for the purpose of carrying the tobacco from the East coast of Sumatra to Singapore. The freight charged by the North-German Lloyd and the Ocean Steamship Company form Delhi to Europe amounted to f.50 and f.40 per last respectively. A total of 129,918 bales in 1888, against 125,766 bales in 1887. It may further be observed that the total crop of 1887 amounted to 144,000 bales, against 138,512 bales in the preceding year, 145,000 bales being shipped from Penang.—*L. & C. Express*, Oct. 25th.

THE BOMBAY COTTON INDUSTRY.

BOMBAY, Nov. 4th.—The cotton millowners in September passed a resolution to the effect that owing to the over production and consequent accumulation of stock in China and the large reduction in prices of cotton-twist, the work in mills be stopped eight days in three months from October to December. Forty-five mills agreed to the arrangement, which was duly observed in the first named month: but during the period a slight revival in the trade was noticeable in China and Japan, and, rates advancing, a desire was expressed to set aside the resolution. A circular was sent round last week intimating that the signatories to the arrangement might revert to the old usage of stopping their mills for two days in the month and on recognised holidays.—*Pioneer*.

CEYLON TOBACCO.—I saw your Deli correspondent's letter, that he did not consider the price that we got for our Bremen lot was good. He did not take into consideration that the tobacco we sent was all of the very worst description, and of the coarsest variety, but the tobacco was well cured, which our Deli friend said we could not cure in small lots, in a previous letter.—W. G.

THE SUPPOSED "CORNER" IN TEA.

(From the *Home and Colonial Mail*, Oct. 25th.)

The following letter appears in today's *Financial News* :—

SIR,—An interesting clique is just now attempting to boom the tea market, and it must be admitted that the statistical position of stock and visible supply is stronger than it was in the memorable year of 1879.

Many of your readers will doubtless have a lively recollection of that ill-advised speculation, and its consequent results. Figures then apparently proved conclusively that it was impossible for any more tea to arrive, and that we should have a tea famine in the spring.

A reference to results will show that the heaviest quantity arrived that season. Further the country traders paralysed the boom by simply shutting down and waiting until they got the article at their own figure. In the meanwhile old stocks were worked off and any purchases made were of a limited character.

Intending outside operators would do well to pause and take into consideration two facts :—

1. The reduced output from India is due to finer pluckings. If the prices here rise to acknowledged remunerative figures, the bushes will be stripped as heretofore, and the stuff hurried home. The cable and fast-going steamers have quite neutralised "tea corners"

2. Tea does not now possess the same keeping qualities as that of years ago, owing to too hurried preparation and the best of it rapidly deteriorates in this humid climate. No sane man would attempt to "corner" fresh fish and hold on for a week or so, and the same line of argument applies, with slight extension of time, to the average run of tea.—I am, sir, yours, &c.,

ANTI-HUMBUG.

CAN TEA BE CORNERED.

There has been some talk of a possible corner in tea, and the suggestion has caused some uneasiness. There is a certain degree of plausibility about the story, the statistical position appearing on a cursory glance at the situation to make a corner, or at least an operation for the purpose of raising prices, not only possible but probable. On closer examination the fear is dispelled, and an explanation is speedily forthcoming of the circumstances which seem to be tending towards higher prices in tea. The contention of those who anticipate a corner is, that stocks are much smaller than they ought to be in view of the fact that considerable arrivals of new season's teas have taken place and much smaller than is consistent with the continuance of the present low level of prices. It is pointed out that the stock of China tea is attenuated to a degree never equalled before; that the receipts of tea from India are short of those of last year instead of ahead, as was expected, and that Ceylon has not sent forward so much tea as was estimated to come from that source. All these statements are perfectly true. Were no explanation at hand it would be justifiable to assume that in view of a brisk demand—deliveries lately exceeding imports of some kinds of tea—prices should rise, and it would be not difficult to believe that some farsighted speculators had been buying largely in the hope of profiting by the expected advance. Besides, events seemed to confirm such theorisings on the outlook. There has been a distinct if not a sustained stiffening in prices, due perhaps partly, though not wholly, to speculative purchases of tea. But it would be a mistake to give too much importance to these facts, which are partly accidental, and do not form any portion of an organised movement in the direction of permanently enhanced values for tea.

The diminution in the stock of Chinese tea is easily explained. The consumption of it in this country has shrunk so in late years that a much smaller stock is consistent with safety than used to be the case. The market hardly seems to have reasoned that out. One is so little accustomed to dwindling markets that it is difficult to tumble at once to the conditions of a trade moving in that direction. We are in the habit of looking for an increase in stocks of commodities, and a falling off causes instinctive alarm. But it follows that if an extending area and amount of consumption require proportionately increasing stocks, so a diminishing market may be kept in equilibrium with smaller stocks. Thus the smallness of the stock of China tea as compared with former years need occasion to no anxiety. As to the smaller volume of Indian imports this year, it must be remembered that the Indian production has been so rapidly and constantly progressive that the slightest halt in it is apt to be exaggerated. That is the case just now. The Indian outturn this year was almost certain to be short of the estimate, which was based on former experience, because there has been a distinct change in the policy of the growers. So much favour has been shown in the market to the finer Indian teas, that growers see it is to their advantage to devote more attention to quality than to quantity. The leaves are consequently being picked at an earlier and tenderer state of their growth, and as the leaves are smaller the output must also be smaller. The improvement in quality thus secured should also tend to produce a rather higher level of prices. There is still the shortness of the imports from Ceylon to consider. Here also an explanation is speedily forthcoming. The earlier part of this season was very cold and damp in the island, with the result that the growth of tea was seriously retarded. At the close of the wet season the bushes began to grow vigorously, and though the crop has been kept back in point of time, there is no expectation that it will fall far short of the estimates. It is thus evident that the three features of the position of the tea market which have given rise to fears of scarcity and high prices, do not necessarily bear that construction or justify these inferences.

Passing to more general considerations, there are one or two circumstances which make a tea corner improbable. Dealing in tea futures is quite in its infancy, being but a few months old. There were serious obstacles in the way of introducing the system. Tea is an article which cannot be made to conform to such market formulas as "good merchantable brands" or "good middles." Every cargo—every series of packages—is bought and sold on its merits, after careful tasting and examination, and the variations in flavour and quality are infinite and innumerable.* To undertake to deliver tea of a certain quality at the end of a fixed period would, therefore, be extremely dangerous. The difficulty has been overcome by the fixing of a variable "type" for tea futures by the Produce Clearing House. Tea sold in advance is required to conform as nearly as possible to the type, but a variation of a halfpenny a pound in value is allowed either way. The type adopted was that of tea rather above the average Congou, there being a feeling in the trade that no encouragement should be given to the importation of inferior classes. When delivery is to be made, the tea proposed to be delivered is tasted by two experts, whose judgment is subject

* They are certainly not INFINITE (that is an attribute not of created things, but of the CREATOR). Neither are they numberless: they are just very numerous.—ED.

to the revision of an arbitrator. The value of the accepted type of tea is about fivepence a pound, and according as the tea to be delivered varies above or below this, within the limit of a halfpenny, or eight points, allowance is made.

This system has been found to work very well, and transactions in which totals of from 10,000 to 12,000 packages are involved are frequently made in one day in Mincing lane. With the system in such an early stage, a corner is not a very likely experience. Another protection against an occurrence of the kind is the ease with which China and India could be played off against one another in the case of a corner. Distributing merchants find that the demand in this country is all for Indian and Ceylon teas, but if the wholesale values of these were put up to figures prohibitive of the cheap retail prices which the public looks for, it is certain that the dealers would average the cost by mixing cheap China teas with the Indian product. The experiment would be somewhat risky in view of the pronounced taste for the Indian flavour, but as British consumers insist rather more strongly on cheapness than on flavour, a movement of this sort would certainly be made to combat any serious attempt to corner tea in this country. Taking all these circumstances into account, we are strongly of opinion that the fear of a tea corner may be safely dismissed.—“*The Rialto*” in *Indian Planters' Gazette*.

PLANTING IN FIJI.

TO THE EDITOR OF THE “FIJI TIMES.”

SIR,—Returning from a tour round Vanualevu, a few lines on some of the leading products of Fiji may interest your readers. In these times of depression, the planters here seem to rely too much on copra, to the neglect of other profitable products such as coffee, cacao and tea. Had the price of copra kept up, coconut planters would have been rewarded for their many years of patience and hard labor; but there is proof before us at every turn that an effort must be made to grow several products on the one estate. Why should people purchase coffee, sugar, cacao and tea when they can grow them on their own plantations? It is seventeen years since we have worked the soil of Fiji in the old cotton days and commenced coffee cultivation at Kandy (Kade) above Sandalwood Bay in Bua. We revisit the old plantations and find them suffering from want of labor. Coffee Arabica and coffee Liberica are still alive, the latter doing very well, and cacao well worth cultivation in sheltered places, but the most reliable product is tea, for on this property, “Masusu,” under the management of Mr. Barratt, fields of tea may be seen equal to any to be found in India or Ceylon. There are forty acres of Assam hybrid in bearing and giving 400 lb. per acre. This tea could, by cultivation and reasonable labour supply, yield 600 lb. per acre, for it compares favourably with any seen in Assam and better than tea of the same age in Ceylon.

After exploring the mountain ranges between Bua and Wainunu, I feel convinced that, in this district of Wainunu, one hundred and fifty thousand acres are suitable for tea growing. With the correct rainfall and temperature—an average of 139 inches of rain for eight years—what could be better than that?

The tea manufactured has sold well at prices ranging from 1s 3d to 1s 6d per lb. The pluckers have brought in from 40 lb. to 100 lb.* of green leaf per day. This would satisfy the most

exacting Indian planter. The large nurseries, containing about 400,000 plants of the best description, would plant about 250 or 300 acres, or open up the whole 400 acres of this block, 150 of which are now in cultivation, 70 in tea and balance in other products.

TEA.—Now that Messrs. Stephens, Barratt and Simpson have pioneered this enterprise, seed and plants can be obtained from them of the best Assam hybrid varieties without the risk of importing seed from India or Ceylon. Plants are better than seed, planted 5 × 5 or 6 × 6. Wide planting is better than close planting to give the bushes light and air and full play for their roots; and a stout plant from the nursery, with a sound tap root, will bear in two years, and give heavy crops in four years from 400 lb. to 600 lb. per acre; and, as they grow older under careful cultivation, give up to 1000 lb. per acre. This has been done on estates I can name both in Assam and Ceylon. Tea does not require pruning every year if plucked often and regularly; it is when flushes run away for want of labour to pluck that the bush falls out of order and runs to flower and seed. Good jat plants will not flower and seed when very young, and it proves a bad jat (or quality of bush) to be rooted out and thrown away, as kidney cotton used to be from Sea Island cotton of good, silky, strong staple. Tea will be the most paying product in Fiji where the rainfall is over 90 inches; a hot steamy climate is the place for growing tea to pay. I will not occupy your space with details of one estate, but will write generally of the island of Vanualevu. It is matter of regret that so many of the old settlers have disappeared from districts where European enterprise once flourished; but it is not too late to help those who remain by giving them every encouragement by assistance with seeds and plants of tropical products, and granting suitable land on easy terms of payment. The following hints may be of some service.

COFFEE ARABICA.—Though coffee is still diseased, and has been since 1869 (twenty years), it is still cultivated with more or less success in India, Ceylon, Java, Brazil and the West Indies; and now that slavery is abolished, the Brazilian crop of 10,000,000 bags will diminish year by year until the prices will go up higher than ever they were before, viz., 120s. or £6 per cwt. Coffee should be topped low and not too heavily pruned, and manured with cattle dung regularly. Coffee planted 6 × 6 in two foot holes would bear in 2½ to 3 years and pay for cultivation say £6 per acre; anything over one cwt. would be profit, and coffee has given one ton, and often given 10 cwt. Estates in Ceylon giving one and two hundred weights per acre are kept up and the cinchona trees scattered about waiting for a better market.

COFFEE LIBERICA.—This hardy variety stands the repeated attacks of H. V. coffee leaf disease better than coffee Arabica, and being a larger tree should be planted about 10 × 10 feet apart; not topped, but allowed to grow pyramidal-shaped unless broken by wind, then saw them down and handle out the centre about a foot or 18 inches all round. The coffee is as good as the other for drinking and some people like one as well as the other; but if there is any objection to the flavour of Liberian Coffee, it can be mixed, after roasting, with a proportionate quantity of coffee Arabica.

CACAO.—This product thrives as well in Fiji as in Jamaica and parts of Central America, and should receive all the attention such a valuable plant deserves. It grows freely in all parts of Vanualevu. Messrs. Holmes, Wilkinson and Simp-

* O! Harry Cottam, Harry Cottam, oh!—Ed.

son can supply seed from fine specimens growing on their respective plantations and I hear the Government offered plants free of charge. The father of botany called cocoa or cacao "food for the Gods." It certainly is a valuable addition to the products of Fiji: and, made with milk and flavoured with spices as in Jamaica, gives more nourishment than coffee or tea. It should be sown at stake in large holes, as it is a plant impatient of transplanting.

FRUIT TREE CULTURE. The cultivation of fruit trees of all kinds is one of the improvements to be found in Fiji since my last visit and many Indian and Ceylon trees are now in full bearing. The mango in particular flourishes in the red soil of Bua and does well everywhere in sheltered places.

A valuable addition is the Avocado Pear of the West Indies. There is one in full bearing at Bua and the owners of it find its value as a vegetable, eaten with meat and improved by pepper and salt. Oranges, lemons, citrons, shaddocks and limes thrive all over Vanualevu and might be made marketable at any time. Guavas of variety are growing wild and can be gathered by tons at certain times of the year. After all we hear of the damage done to Fiji by the hurricanes, the fruit trees thrive still, whatever the coconut palms may have suffered.

GROUND PROVISIONS.—Yams, dalo, sweet potatoes, or kumalas, seem scarce, all attention being devoted to copra-making and cattle rearing. There is no reason why food gardens should not be fenced or walled in and a good supply kept up. Bananas are not so large as those of the West Indies and it would be well to introduce some new varieties.

Trusting the above few lines will be useful to settlers in Fiji.—I am, &c., HENRY CORTAM.
Wainunu, 17th September, 1889.—*Fiji Times*, Oct 5th.

THE NEW GOVERNOR OF JAMAICA ON THE CAPABILITIES OF THE COLONY.

At a meeting of the Committee of a proposed Jamaica Exhibition Sir Henry Norman's successor gave a good exposition of the possibilities before the colonists, thus:—

Gentlemen,—The circular letter inviting you to meet me here today will have explained to you the object of this meeting. It has struck the Board of the Jamaica Institute, and the idea has commended itself to me, that it would be beneficial to the people of this island, if an Exhibition could be arranged, of our natural products and manufactures, and of some of the products that we import from other countries. Exhibitions are no new experiments, and the eagerness with which various nations have followed the example set by England in 1851, is a proof of the practical benefit to be derived from them. It has been found that an Exhibition of the resources of a country, is not only the best advertisement for business purposes, but is the most valuable industrial education for the people. It is not my intention to map out here, save in the broadest lines, the scope of the Exhibition; that is a matter to be settled by you, gentlemen, if your approve of my suggestion. I know that as we go on the scheme will necessarily be modified, and probably enlarged, so that out of the rough idea, the details will gradually shape themselves. The proposal as it stands at present is that we shall have in November or December of 1890, an exhibition of our products and manufactures and invite the countries from which we import food stuffs or machinery to send exhibits for our information. Then it is proposed to add to the attraction of this exhibition by obtaining the loan of any objects

of art or interest that may be intrusted to us. At the same time the cattle show may be arranged in connection with the exhibition, so that visitors can see for themselves how splendid are the herds that are raised upon the rich pastures of our plains and valleys, while a flower show will add grace and beauty to the whole. But first we want to exemplify our products; and when I say our products, what can we not produce? Three hundred years ago the Spaniards made wine in Jamaica, and certain portions of the Island will now produce grapes equal to those of California. One thing the Spaniards could not grow, nor can they grow it now in Cuba—the olive—but we have in the avocado pear a fruit that produces an oil finer than the finest oil of Lucea. There are eight heads under which the staple products of the future may be divided:—Sugar and rum, fruit, coffee, cocoa, fibres, rubber, tobacco and dyewoods. The acreage under canes has been steadily decreasing for the past fifteen years, and prices have until this year been driven down by the action of foreign bounties. Well, gentlemen, we may learn by ocular demonstration that there are means, either by improved treatment of the canes or better machinery, or methods of manufacture that if adapted may restore the balance of profit to the grower.

If we are to believe the papers, and I see no reason to doubt the statements in the press or the subjects, the treatment of our fruit, especially our oranges, looks almost like a deliberate attempt to murder what may yet be, and *will yet be* a great trade. We can show at our Exhibition how oranges ought to be graded and packed, and once more we may retain the character in the American markets that Jamaica has so unwisely flung away. We can bring before growers and purchasers the various ways in which fruit can be preserved, and who can tell what minor products will be brought to light by the Sub-Committees in the Parishes. I mentioned two products for which there is an expanding market. They are fibres and rubber. Apart from the want of fibres for cordage and textile fabrics, there is, with the spread of education, a growing demand for paper. Why should we not add to this supply of material, or even make the paper ourselves? We have great capabilities for growing fibre plants, and I may tell you that steps have been taken by the Botanical department to procure as many plants as we can get, and demonstrate the practicability of making the fibre cultivation a paying industry. Again, with the advance of Electricity the importance of India rubber is increasing daily. I believe that we have within the island a plant that produces indiarubber of peculiarly good quality, and Mr. Fawcett is patiently experimenting upon it to see if when planted systematically it will give as good results as when growing wild. There are two products out of many that may have a great future before them in Jamaica. Then look at our woods. We have hundreds of thousands of acres producing splendid timber which, with proper regulations for the prevention of undue destruction would be most valuable. These are some of our possibilities. Blessed with a country whose lofty hills are fertile as the green valleys reclining at their feet, we could duplicate the choicest products of almost every clime! Will we strive to do so? Will Jamaica stand with eager eyes looking forward, speculating on what may be and striving to attain it, or will she be content to sit with sleepy visage and folded hands waiting for cozy Fortune to come and seek her and idly dreaming of what might have been? It may be that as the idea develops, we may see our way to inviting the other Colonies of the West Indies to send exhibits of their produce. The time is opportune, as probably all the islands will be preparing for the Imperial Institute, and their exhibits might come here on the way. Other divisions of the Empire have had their Exhibitions, and though we have not the means to match them in extent, we can in some modest form secure for ourselves and confer upon others the benefit to be derived from the examination and comparison of the productions of the different islands. To carry out the idea of the Exhi-

bition will, of course, involve the Expenditure of money and for any possible deficit, I will ask you to mark the measure of your sympathy with the movement by the amount of guarantee that you are prepared to give. When we remember the enormous benefit that such an Exhibition must confer upon Kingston, I have no fear that a substantial guarantee will be obtained. The time is propitious, and although there is a lull at present, business is improving. The black bat, Adversity, has flown away behind us, and already, we see bright Prosperity soaring towards us on golden pinions, and let the venture succeed, as I believe it will, or let it fail to pay its way, at least 'twill show that Jamaica is up and doing, ready to stand in the forefront, and to take her natural position as the Queen of the British Antilles.—*Gleaner Packet Edition*, Sept. 25th.

JOHORE NOTES.

Oct. 31st, 1889.

I am glad to see in your paper that Michaelstowe tea is gaining ground in Singapore. This is as it should be: for I always maintain that Singapore should help its next door neighbour whenever it can.

I have just visited the tea estate myself and can testify to the excellent appearance of the bushes and to the nice flavoured tea that they produce. The pekoe especially is so sweet a tea as almost to suggest its having been artificially scented: but Mr. Mackenzie assures me that this is not the case. By-the-bye, he told me a very good story of his trying to do business in Singapore. Among other places he went to a hotel and introduced himself to the worthy proprietrix who immediately cried out "Oh! You're the man that sent me that bad tea!" On enquiry he found that the good lady had allowed it to stew, as you can, with impunity, stew the chopped straw that is sent down from China; but the result of stewing Johore tea was that "mine hostess's" head was nearly blown off by tannin! She went on to say that she had to get her tea now from Maynard & Co., and showed him a sample which he recognised as his own tea, supplied some time ago to Maynard & Co! Let me recommend those who have not yet tried the Michaelstowe tea to do so without delay; pekoe for choice. Mr. Mackenzie delivers it at Holley Stables and he is not too proud to execute a 2 lb. order.—*S. F. Press*, Nov. 5th.

BARK AND DRUG REPORT.

(From the *Chemist and Druggist*.)

LONDON, October 31st.

ANNATTO.—For 1 small bag of fair bright Ceylon seed 2½d per lb. was paid, and 9 baskets dry hard brazilian roll annatto were bought in at 1s per lb.

ARECA NUTS.—Thirty bags sold at 15s per cwt., which is rather an improvement, we think, upon the last sales at auction.

CARDAMOMS.—A rather heavy assortment was offered today, about 250 packages being placed in auction, of which about 110 sold at lower rates all round, the decline being irregular, but ranging between 3d and 6d per lb. Ceylon Mysore: fine bold pale 2s 9d to 2s 11d; medium 2s 2d to 2s 3d; small 1s 3d to 1s 7d per lb. Medium, long pale 1s 9d; medium size, full, but grey colour 1s 6d to 1s 7d; small ditto 1s; bold ditto 1s 10d; small to medium brown 7d to 1s. Ceylon Malabar: fair medium brown round 1s 8d; small 1s; small to medium pale grey round 1s 5d to 1s 7d; small brown 1s 3d; ordinary 6d to 7d; specky and loose shelly mixed 7½d to 8d per lb. Thin Wild Ceylon, without reserve 5½d per lb. Seed, from 1s 4d to 1s 8d per lb.

CINCHONA.—At today's auctions South American barks sold well for some varieties; one lot of good Loxa at 1s 10d; Guayaquil, good long silvery quill 10d to 11d; ordinary split and damaged 5d to 6d per lb.; fancy brands bought in at 1s 6d per lb. Forty bales spurious Calisaya, bright colour, very bold and hard, were partly sold at 1s 2d per lb. for sound.

The exports of cinchona from Java during the first two months of the season (July and August) have been as follows:—

	1885	1886	1887	1888	1889
Govt. Plant., Amst., &c	95,263	83,282	119,559	11,021	122,143
Private plantations	128,971	285,094	502,501	424,432	634,190

Total 224,234 368,376 622,060 436,453 756,333
Our imports this week have been 322 packages, and for next Tuesday's auctions 1,220 packages have so far, been declared, including 842 Ceylon, Java and India, 206 West Coast Africa, and 172 Bolivian Calisaya.

COCULUS INDICUS brought an advance of 50 per cent on the price last paid at auction, 26 bags of good quality being sold today at 12s per cwt.; damages and sweepings at 10s per cwt.

QUININE.—At the end of last week a pretty considerable business took place, the Auerbach agents alone selling 100,000 oz. December-April delivery at 1s 2½d per oz. Since then the market has been very quiet, with sales of about 50,000 oz. altogether at 1s 2½d, usual terms, and 1s 2½d cash on the spot, and 1s 3d November-February.

THE DUTCH MARKET.

AMSTERDAM, Oct. 30th.

CINCHONA.—The sales which will be held at Amsterdam on November 7th consist of 2,188 bales and 114 cases, totalling about 189 tons, and classified as follows:—Java bark from Government plantations, 446 bales 48 cases, about 39 tons; from private plantations, 1,742 bales 66 cases, about 150 tons. Druggists' bark: Succirubra quills, 25 cases; broken quills and chips 160 bales 78 cases; roots, 80 bales; C. Schukkrufft quills 6 cases; broken quills and chips, 34 bales 2 cases. Manufacturing bark: Officialis, broken quills and chips 55 bales; Leigeriana, broken quills and chips, 1,546 bales; roots, 213 bales; Hybrid quills 2 bales 3 cases; broken quills and chips, 32 bales; root 66 bales. The manufacturers' bark amounts to about 160 tons, and contains about 6,420 kilos. sulphate of quinine, or 6.5 tons, or 4 per cent on the average, viz. :—About 4.5 tons contain 1 to 2 per cent sulphate of quinine; 37.3, 2 to 3; 66.4, 3 to 4; 17.5, 4 to 5; 12.8, 5 to 6; 9.9, 6 to 7; 7.4, 7 to 8; 4.5, 8 to 9.

TOBACCO IN SUMATRA AND CEYLON.

We extract the following from the Dili letter (31st Oct.) of an ex-Ceylon planter:—

"I am extremely busy at present, and no time to write you at length, but I may say that I have read the Bremen report on the small parcel of Ceylon tobacco, but do not like you consider it encouraging—far from it.

"I am inclined to the opinion of a correspondent of yours, who, when speaking of tobacco, aptly quotes:

'Muckle cry and little oo,

As the Deil said, when he clippit the soo.'

Prices for our tobacco this year have been of an extraordinary character; some estates getting exceptionally high prices, and other well-known and favourite marks fetching far below paying rates, with the result, that unless we can continue to send corer leaf of a very light colour and texture, many estates will have to shut up.

"The heavy expenditure attending the cultivation of a tobacco estate makes it a serious matter for a private individual, if there is even only a slight loss, hence the great run there has been lately in the London market, in forming companies, to all of which I wish every success. Wishing all in Ceylon every luck, be it in tobacco, tea, or anything else."

INDIAN TEA NOTES.

DEHERA DUN, Oct. 16th.—Seasonable weather is the news from the Dun. We have nearly finished plucking and are getting in very little leaf.

CHITTAGONG, Oct. 17th.—The rains ceased about 5th October and further showers are much wanted. The nights are getting cool. Oct. 22nd—Notwithstanding the deficient rainfall (over 40 inches, as compared with last year at some concerns) there has been a fair show of leaf, and some of the Northern gardens are ahead of last year in manufacture. Rain is wanted for both tea and rice.

CHITTAGONG, Oct. 29th.—The weather has been unsettled for the last week, and most concerns have had good rain. The cold weather will probably set in now, as flocks of pelicans passed down south this morning.

MUNGLEDYE, Oct. 28th.—Hot dry weather. Leaf getting generally scarce. Slight earthquake at 7-45 a. m., morning of the 26th. Rain threatening, much wanted; but few gardens will pack estimate. Much dissatisfaction expressed at recent circular of Steamer Companies. Steamers calling here very irregularly.

OUR latest from Habeeungee is:—The rainfall for the last week has been upwards of five inches. Since this rain the temperature has fallen considerably.

IN tea, coffee and other plantations 363 lakhs of paid-up capital are invested, of which 344 lakhs are held in Bengal, most of the tea companies being registered in Calcutta.—*Indian Planters' Gazette*.

DRY GOODS AND TEA DEALERS.

A tea counter has become a feature in the leading dry goods stores, chiefly through the efforts of parties interested in the introduction of blended India and Ceylon tea.* This is an innovation, but it is difficult to draw the line now-a-days and say where the mammoth store, dealing in dry goods, notions, boots and shoes, clothing, bric-a-brac, house-keeping utensils, toys, furniture, crockery, trunks and other lines of merchandise, shall stop. We believe in a live-and-let-live policy and question the wisdom of concentrating the distributive trade in large retail stores. Such a policy weakens a multitude of customers whose patronage is of value to the dry goods store, but whose purchasing power is reduced the moment the dry goods dealer becomes a universal provider. Silk and syrup will not mingle, and we have no fear of dry goods dealers going fully into the grocery business. We believe wiser and better policy would be to leave the tea and coffee counter to those whose business fitted them to be dealers in food. If not, then the grocer can retaliate and put in stock of toilet articles and notions generally.—*American Grocer*.

THE TEA FOR AMERICA.

(BY THE "PERIPATETIC PLANTER.")

* * * Notwithstanding all I have written on the subject of taste, "Cachari" maintains his position of lawgiver in the matter of Taste, to all the World in general and to Americans in particular. Because he esteems Indian black teas, and deems them "best" as I do for that matter, he will not allow that others less interested in Indian teas, are of a different persuasion! He will not allow that, to tell an average man that his taste is all wrong, is almost an insult; and that to "educate" his taste, of necessity implies an evolutionary process. Give a man an olive for the first time, and your highest praise only provokes pity for your taste. Argue with him as you may, you leave him of the same opinion still. You can't coerce him into appreciating that olive with your palate. Prepare them for him; soak out the salt; give them to him cooked with his *entrées*: by degrees he will appreciate their flavour, and in time

* N. B.—Ed.

participate in the full enjoyment you receive from them. Do you expect to make a warm friend of a man by telling him that his wine, the wine he appreciates so highly, is poison? Take "Cachari's" own stand-point, that Indian teas being *he knows*, the best, people who prefer other teas, must be wanting in judgment—fools in other words. Does not even proverbial philosophy warn us that, "it is better to humour a fool than to fight him?"—not to quote Holy Writ.

Enthusiasm is an excellent thing, and a necessary item in one's psychological equipment now-a-days—but discretion is no less a necessity, otherwise Don Quixote would be an ideal leader.

One little personal matter may be referred to, in passing away from these platitudes; "Cachari" says:—"A difficulty does exist, but not the one 'P. P.' points out, that of overcoming the taste acquired by the American public for green-teas, but of overcoming the prejudice of the existing trade, who have retailed your teas so profitably to themselves in the past."

"Your teas," I presume, is a misprint for *green* teas, otherwise the paragraph would be nonsense. This statement does me scant justice, seeing that I have over and over again raised the point of the vested interest of the trade, in America, as an important enemy in the way of the progress of Indian black tea—and have used it to advocate long, long ago, a very similar system for pushing Indian teas *properly manufactured and blended* in America, as that just propounded as a novel idea by "Cachari":—who merely leaves out the part of the Prince of Denmark from the play of Hamlet, by failing to provide the chief item in the Enterprise, a tea suitable to the end in view!

In the meantime, as every pound of Indian black tea, sold by accident or design to a green-tea drinker in America (instead of to a black-tea drinker) is certain to make an enemy of that purchaser, who will take care to warn his friends against "the horrid stuff," of course, I go so far as to look upon the unrestricted sale of Indian black-teas to other than black-tea drinkers in the United States, as the worst possible policy—and no less than suicide.

If Americans only require to be introduced to Indian teas to at once appreciate them with "Cachari's" palate, how is it, may I ask, that time and again, one meets Americans in London who declare, "they can't get a cup of tea in all London fit to drink, it is all beastly black stuff, and not a bit like the exquisite, flavourably light tea they can get in the States!" This I solemnly declare, I have heard over and over again. Yet Indian tea is now the vogue in London! and those Americans were not referring to the Hotel teas only. The taste for "green-teas" takes a strong hold when once it has been acquired, more especially the better kinds of Japan teas, as I know personally; having for a considerable period longed for Japan tea in Assam, after having got used to it in Japan; until after a year or two, through the enforced necessity of having to drink Assam tea daily (which necessity, remember, does not exist in America) I, too, like "Cachari," learned to appreciate Indian tea.—*Indian Planters' Gazette*, Nov. 5th.

INDIAN AND AMERICAN COTTON SEED.

The *Pioneer* thus writes:—

The question of a possible development of the exports in Indian cotton seed has arisen out of a remark made on the subject by Mr. O'Connor in his Review on

the Trade of India for the year 1888-89. America does an extensive trade in this article with Europe, and the fact that so large a cotton-producing country as Hindustan only supplied in 1888 4,000 out of the 250,000 tons consumed in the United Kingdom seems significant enough to require explanation. A Calcutta contemporary, commenting on Mr. O'Connor's opinion that India should contribute a larger share of England's requirements, points out that the difficulty in the way of cultivation of what ought to be an important branch of our export business exists in the impracticability of entirely freeing Indian seed from the adherent fluff. At the same time the suggestion is offered to the Agricultural Department that attention might be advantageously directed to seeking a remedy. What the Calcutta paper says is true as far as it goes. No machine has yet been found capable of cleaning cotton in the North-West Provinces and the Punjab at all events so thoroughly and efficiently as the native *chuckee*. The various patterns that have been experimented with from time to time have each in turn either given a poor result in general outturn or developed the fault of cutting the staple, a contingency not easy to avoid owing to the tenacious manner in which the fibre naturally envelopes the seed.*

There are other conditions, however, still less negotiable which militate against the establishment of a foreign trade in cotton seed. In the first place, in the Upper Provinces at least, and we believe in other cotton-growing districts as well, the production is utilised as fodder, for which purpose agriculturists readily pay prices that range from 30 to 50 seers for the rupee, according to the season. But the real crux of the matter is that Indian cotton seed contains a very much smaller percentage of oil than that of America and Egypt. So inferior is it in this respect that, as long as the two countries named continue to supply the European markets, there is but a remote likelihood of the Indian variety ever securing an appreciable footing there. All vegetable oils in India command prices that are high considering the average income of the great body of consumers, and were it possible to obtain a cheap oil from cotton seed in paying quantities it would have been done long ago. When local native crushers with their patient methods and indifference as regards expenditure of time and labour find it unprofitable to extract the oil, it may be taken for granted that the business is not worth the attention of home manufacturers.

This disadvantage under which Indian cotton seed labours is all the more regrettable when it is considered that it tends greatly to encourage carelessness in the ginning; whole seed being no great object, less attention is naturally devoted to the operation, the result being an undue proportion of crushed capsules left in the cotton, and consequently more or less depreciation in the market value of the staple. Moreover, the ginner can thus go lightly to work in adulteration, first, because he will avoid the trouble of proper cleaning, and second, because of the profit he will derive from the increased weight given to the cotton by the bruised seed. A reference was made on this subject by the Agricultural Department some time ago in connection with the possible risk of spontaneous combustion from the existence of a readily oxidised oil in the cotton, but the matter has apparently been allowed to drop, presumably owing to the fact to which we have drawn attention, viz. that Indian seed contains comparatively little oil, and that there is consequently little danger from its presence.

SUFFERINGS IN CHINA TEA DISTRICTS.—A native just back from the tea districts informs us (*Foochow Echo*) that much distress prevails amongst the people, especially amongst the owners of tea gardens, by reason of the great reduction in the usual picking of the leaf, and the uncertainty of payment for what they have sold. News has long since reached all the tea districts of the tremendous losses tea men have suffered. Affairs look so dark upcountry that no pressure will be required next season to curtail the supply.—*Overland China Mail*, Oct. 30th.

* This difficulty might be obviated by the seed being ea refully sing ed.—Ed.

DISEASES OF PLANTS.—We are pleased to announce the publication of a little book on the diseases of plants, from the pen of Professor Marshall Ward, whose work on the diseases of timber we had occasion lately to notice. We shall take an early opportunity of alluding to it at greater length, but in the meantime, we may say that it is published, at a low price, by the Society for Promoting Christian Knowledge.—*Gardener's Chronicle*, Oct. 12th.

THE ANNUAL REPORT OF THE NETHERLANDS INDIA AGRICULTURAL COMPANY has been issued. It shows that the deficit of 58,000 guilders on the balance of the preceding year has been reduced to 915 guilders, ascribed to a more plentiful crop on the new undertaking of the company and the good prices realised for coffee. About 4,500 piculs of good, even very fine quality of coffee were received from the four estates, which realised at an average a price of 51 11-100 cent per half-kilo. The issue of the remaining 210 shares has enabled the company to extend the cultivation by 75 bouws on Sono Sehar, and 50 bouws on Wonokerto II. The undertakings are in excellent condition, and the expected crop will not be under the estimate. The balance-sheet shows an amount of 769,116 guilders invested in agricultural undertakings, 300,000 guilders in capital, and 800,000 guilders in a bonded loan. From the profit and loss account it appears that the deficit of the preceding year was 58,235 guilders, interest account 3,244 guilders, expenditure 5,681 guilders, and the total debit 72,661 guilders. Profit on securities was 835 guilders, profit of the undertaking Soember Mangis 37,386 guilders, profit of the undertaking Sono Sehar 33,525 guilders, making a total profit of 71,746 guilders, the deficit being thus 915 guilders.—*L. and C. Express*, Oct. 18th.

COFFEE.—Reviewing the present position of the coffee markets, Mr. Anton Hvistendahl points out that since June last Rio de Janeiro coffee has advanced in the New York market from 15½ cents per lb. to 19½ cents per lb. During the same period, he adds: "We have seen consumption continue full swing, in spite of this advance, we have seen a Cabinet Minister in Holland take action to protect the interest of the state as a large owner of coffee plantations against the artful manipulations by 'bears' in the terminal markets, and we have seen the Rio market for eight consecutive weeks resist—and with success—all attempts to depress the value of the bean." The lesson which the quoted authority draws from these facts is that the control of the price of coffee has passed from the hands of the consumer into the hands of the producer. "What this implies," he continues "is well understood by leading merchants in the trade, but it is neither realised nor understood by the majority of operators in the terminal markets. For years past we have had a full supply of coffee to meet the requirements of consumption, and in such circumstances the large shippers and importers have had the principal influence in determining the price of the article on behalf of the consumer. But we are now, for the first time since 1873, in a season when supply undoubtedly is insufficient to meet the requirements of consuming markets. In such a season the power of the manipulator may not be wholly extinguished, it is true, but it will be far less effective. Combinations formed in such a season for the purpose of depressing prices are certain to end in failure, although they may have a temporary show of success. In such a season, too, the prospects of the next crop must take a secondary place as an element influencing price. The size of the crop that is being actually marketed will be the chief factor. In such a season it is a question not of 'flowers' but of 'coffee,' and it is obvious that no coffee of next crop can reach consuming markets before July, and then only in dribbles."—*H. and C. Mail*.

MANURING HILLSIDES.—The bottom of a hill in the valley is undoubtedly richer in vegetable matter than the sides, unless the latter have been recently and heavily manured. But it is a fallacy to draw manure at any season on a side hill with the notion that it will wash down. We have tried that repeatedly, and the manure never fertilized much, if any, below the line where it was drawn. Undoubtedly rains washed over the land and the manure on the soil below, but the valuable properties of the manure were deposited where it lay, while the deodorized water passed on below. It is doubtless to this necessity for water saturated with manure to sink that running streams and large bodies of water owe their power to cleanse themselves. The nitrates are heavier and sink to the bottom. Hence the mud from ponds and running streams becomes such valuable manure in many cases. It contains most of the fertilizing elements that the water above it has contained.—*American Cultivator.*

THE JAVA CINCHONA PLANTERS AND THE FALL IN THE PRICE OF BARK.—The Secretary of the Soekaboemi Agricultural Association sends us a copy of a memorial addressed by the Committee of that body to the Minister for the Colonies at the Hague, dated 25th October 1889. Translated into English, it runs as follows:—

The Committee &c. have the honour to state: That the present low position in the market of the unit at the cinchona bark sales must be chiefly ascribed to the 'bear' speculating of quinine manufacturers. That a good deal of quinine is sold by these for future delivery, whilst they are as yet not possessed of the bark from which to manufacture it. That this is done simply in order to buy the cinchona bark as cheaply as possible, and that it is proved that some quinine manufacturers could not fulfil their engagements if they had to deliver *immediately* the quinine sold for future delivery. That the inexplicable 'bear' speculating of quinine manufacturers, who must however make a profit by the sale at as high a figure as possible of their product, is only to be explained by the fact, that they forego the profit on the principal item, in order to make sure of the profits accruing in good number from minor items in the manufacture. That in 1885 *inter alia* for 17,000 kilograms of cinchona bark f45,000 net were realized, equal to a unit of 35 cents, whilst in that year the export of cinchona bark from Ceylon was 14,000,000 English pounds. That now in 1889 the unit has fallen to seven cents per half kilogram, notwithstanding that the export of cinchona bark from Ceylon has also fallen to 8,000,000 English pounds* and the consumption of quinine in America in that period of 4 years has increased by 100 per cent. That the Government of Netherlands India is not only a dealer in coffee beans, as Your Excellency a short time ago remarked in an interpellation in the Second Chamber of the States-General, but also a dealer in cinchona bark. That it is our candid opinion that there is no doubt that an equally stringent intervention by Your Excellency in the cinchona market, as recently in the coffee market, may be of very great influence on the raising of the unit and consequently of the prices of quinine. That finally it is of not the slightest advantage to private sellers, if they raise their unit to fifteen cents, so long as the Government factories' cinchona barks are favored *à tout prix*. That as there was a reason for Your Excellency, when the stock of coffee had shrunk from 400,000 bales to 60,000 bales, no longer to part with the Government coffee at a price which the 'bear' party in that product wished to give for it, there is equal, if not more, reason, to make an end of the game in quinine. These are the reasons why the abovementioned Committee beg Your Excellency to take into consideration, to be pleased henceforth to fix the unit of the cinchona barks of the Government of Netherlands India at a minimum of 15 cents for manufacturers' barks.

* The actual quantity exported in the 12 months ended September was 10,498,000 lb.—**Ed.**

ALL ABOUT TOBACCO.—Messrs. A. M. & J. Ferguson have collected from their excellent periodical, the *Tropical Agriculturist*, a series of articles and letters on the subject of Tobacco growth. An index is prefixed. The culture of Tobacco in Britain is alluded to, large use being made, and duly acknowledged, of Mr. E. J. Beale's treatise on the subject.—*Gardeners' Chronicle.*

CEYLON OOLONGS FOR AMERICA, AND THE PRESENT DEPRECIATION IN THE TEA MARKET.—We take the following extract from Messrs. Rucker & Bencaft's Weekly Circular:—

"We noticed in the recent sales some very fairly prepared Oolongs which realized 1s 4½d to 1s 5d per lb. We have already pointed out that the consumption of fermented teas, *i. e.*, Congous, Indians and Ceylons in the United States and Canada is only about 10 per cent of the total tea delivered, Green Teas, Japans and Oolongs, all unfermented teas, amounting to 82 millions, Congous, Souchongs, Indians and Ceylons to seven millions. As we said on Oct. 4th, 1888, for one lb. of Ceylon the Americans and Canadians drink 80 lb. of China and Japan unfermented tea. At present, with a moderate curtailment of plucking it seems likely we shall be able for some time to deal in this country with all the Ceylon tea made, but when it becomes necessary to open up new markets in the United States and in Canada it must be done with oolongs." It is evident that the present depression in the tea market was expected by those interested in the tea trade, because we find that the terminal price of common Congous for November was only 4 10-16ths and for December 4 13-16ths against 5 4-16ths the previous month whilst for January the price is quoted 5 2-16ths and for March and April 5 3-16ths.

EMPLOYMENT OF FEMALES IN TEA FACTORIES IN ANHUI.—The *Peking Gazette* of 9th Oct. contains the following on the above subject (as translated into the *N.-C. Herald*):—

Some one having brought to the notice of the Throne the numerous abuses connected with the employment of women and girls in tea factories all over the country, the Emperor issued on the 31st of August last a Decree ordering a strict investigation into the matter. The Governor of Anhui now submits, in obedience to these instructions, the result of the enquiries which he has caused to be instituted on the subject. The two chief places of tea production in the province are T'un-hsi and Ma-fu, situated respectively in the Prefecture of Hui-ch'ou and the department of Liu-an. By a custom of long standing all the poor females of these districts resort to tea picking every year as a means of gaining a livelihood. The tea factories consist of an outer and an inner establishment, in the former of which the men attend to the firing of the article, while in the latter the woman pick the leaves. Women who live in the vicinity return to their homes every night, those who come from a distance find a home with relatives, and such a thing as residence in inns or remaining shelterless all night is unknown. The presence, however, of such a miscellaneous crowd of people, with good and bad characters intermixed, makes it necessary for the local authorities to exercise careful supervision over these establishments every Spring, and so far the intercourse between the people and the tea merchants has produced no serious result. Exclusive of the above, there are no tea districts in the province of any importance to attract any large gathering of people, and the number of female tea-pickers is so small as to render it comparatively easy to check abuses. The Governor is of opinion that any general prohibition which would prevent women and girls from engaging in tea-picking would from the nature of the case be very hard to enforce, as it would deprive a poor class of people of their only means of livelihood. He acknowledges, however, the necessity of guarding against the abuses engendered by the low state of morality which prevails in this degenerate age, and he promises to do all he can in concert with the authorities of the tea establishments to inculcate a feeling of self-respect amongst the female inhabitants of the tea districts.

LATAKIA TOBACCO.

A writer in the *Geographische Nachrichten* of Basle, on the cultivation of tobacco in the Ottoman Empire, says that Latakia, which gives its name to the famous tobacco, is a small seaport in Northern Syria, which occupies the site of the ancient Laodicea, but the port has been blocked up with sand, so that only small, lightly-laden boats can enter. Behind the town extends a vast plain to the south beyond Jibleh as far as the range of hills in which live the Ansari-h, the descendants of the sect of assassins so famous in the time of the Crusades. This tribe is specially engaged in the cultivation of Latakia tobacco. At the end of December the ground is irrigated, and the sowing takes place in January, ten or 12 seeds being placed in a single hole made with a stick. As soon as the sprouts appear above the ground they are covered with mats, which are raised only when the sun is up. The women and children are employed in keeping off the birds, and in weeding out the weaklings. In February the sprouts are transplanted to another field, where the earth is piled up well about them, in March they are kept well watered, and in April the harvest commences. The first leaves form what is called the new tobacco, and is smoked with delight by the Fellahs themselves, it being stronger than that obtained subsequently. From April to August the plants must be watered according to the state of the weather, and must receive general attention. The real harvest takes place in August and September. The plant is cut, the leaves removed, tied in bundles, and placed on mats to dry in the sun. In November this process is finished, the tobacco is placed in horse-hair sacks, and put on the market. The merchants subject the leaves to a new drying and then sort them according to colour, perfume, and general quality. There are in all three qualities, of which the finest is obtainable only from the more elevated plantations of the Ansari-hs. The plain of Koura, at the foot of Lebanon, also gives excellent Syrian tobacco, the best quality of which is very seldom seen in Europe. It leaves a white ash, while Oriental tobaccos as a rule leave a black or dark gray ash. Other inferior qualities are yielded elsewhere in Syria. In Turkey proper the chief centre of cultivation is Drama in the Salonica province. This district gives about 700,000 kilos. annually, the best quality going to Constantinople, and the inferior to Russia. Pravista gives a poor tobacco, which all goes to Europe. In various other districts of Turkey in Europe tobacco is produced; as a rule it is very inferior, and goes either to Austria or Russia.

ROPES FOR FIBRES.

So much has been written of late years with regard to the adaptability of our native fibres for various purposes, that it would be superfluous for me to attempt to go over the same ground again, but I cannot refrain from making a few remarks on the large quantity of ropes of various sizes imported and used in the Island, while rope-making materials grow everywhere in abundance. This latter fact is recognized, and taken advantage of by the peasantry, indeed many of them partly make a living by the sale of ropes, short lengths—usually about 25 feet long, and headstalls made of fibres from the barks of trees.

The barks mostly used for this purpose are the "Mahoe" (*Hibiscus elatus*, L.) "Trumpet tree" (*Ocrocopia peltata*, L.) and "Burn nose" (*Daphnopsis tinifolia*, Gr.); leaf-fibres are also made use of to some extent, and it is a pity that they are not entirely used instead of bark-fibres. Very strong ropes are made from the fibre obtained from the leaves of the "Keratto" (*Agave Morrisii*, Bak.) "Pinguin" (*Bromelia Pinguin*, L.) "Banana" (*Musa sapientum*, L.) &c.; also from the aerial roots of a species of *Ficus*.

The fibres named are those most generally used, but there are plenty of others equally valuable, and some of them, are very common in certain districts, e. g. "Ippi-Appi" (*Carludovica Plumieri*, Kth.), "Silver Thatch" (*Thrinax argentea* Lodd.), "Ochra" (*Hibiscus Abelmoschus*, L.), "Dagger Plant" (*Yucca aloifolia* L.), several species of *Crotalaria* which are common weeds, "Pine-Apple" (*Ananas sativa*, Lindl.), "Aloe" (*Furcraea cubensis*, Haw.) and many other plants to be

had in abundance, yield good, strong fibres suitable for making ropes and cordage. Nearly every peasant is the owner of one or more head of stock, and he requires rope not only for reins, but also to tie loads on the animals' back and for a score of other uses. When we look at the matter in this light we can form some idea of the large quantity of rope which must be annually required. The use of barks for this purpose should be discouraged, except perhaps the "Trumpet tree" which is very plentiful every where and, as far as I am aware, is of no other value. The "Mahoe tree" which yields the bark most prized, also yields one of our most beautiful and valuable native woods, and in country districts where this tree is plentiful hundreds are killed every year through being stripped of their bark for rope making. I have only alluded to the rope required by the peasantry, but there is no reason why every bit used in the island should not be made here. The machinery necessary for the manufacture of rope is, I believe, simple, and might be worked under the superintendence of any intelligent person. The raw materials are plentiful, and the demand for the manufactured article, if offered at reasonable rates, would, I am sure, be steady and good. I feel confident that a fortune awaits the man with sufficient means and courage to start this industry. He might begin by manufacturing ropes of various qualities and sizes, and when he gains sufficient experience of the relative values of the fibres at his command, and his work people understood the working of the machinery, &c. he could introduce the manufacture of bags of different kinds. The number of these annually required for coffee, cocoa, and pimento, not to mention many other things for which they are used, must be simply enormous. These are small matters, comparatively speaking, and though the total spent on rope and bags by a single member, or estate during the year, may not amount to much, yet, taking the whole island, the money expended on these two necessary articles must be a very respectable sum.—W. HARRIS.—*Jamaica Bulletin*.

CASTOR OIL PLANT.

The Castor Oil plant (*Ricinus communis*, L.) is now extensively cultivated in India and the United States, and the oil, if carefully extracted, is a valuable product. As the plant grows in Jamaica like a weed, it would probably pay to cultivate it. On many sugar estates, it is found necessary to allow the land to go into ruin, piece by piece, in order that it may recover from the exhaustion incidental to the growth of the cane when sufficient manure has not been applied. In Europe, rotation of crops, as well as artificial manures, have taken the place of the old method of leaving the ground fallow, and it is possible that castor oil may be a suitable plant to succeed the sugar-cane, and to grow in exhausted coffee fields. In some parts of the world, it is grown merely for the sake of improving the land. The refuse of the seeds after the extraction of the oil, is also a valuable manure. The soil best suited for the Castor Oil is a sandy loam. There are a great number of varieties sown with small and others with large seeds. The small seeds are considered to afford the best oil for medicinal purposes, and it is therefore advisable to cultivate only these varieties. The cultivation is simple, and similar to that of corn (maize). The yield varies from 15 to 50 bushels (of 46 lb) to the acre; and 100 lb, of good seed yield about 5 gallons of oil. In order to harvest the seed, the best plan is to cut the pods when they are just turning brown and put them on a barbecue. When the pods have all burst, the empty husks can be picked up, and the seeds swept together and collected. The same care should be taken as in coffee, cocoa and pimento to prevent rain touching the seeds; if there are more than 50 acres under cultivation, a drying house is necessary. To extract the oil the simplest way is to bruise the seeds in a mortar and then boil them in bags under water. The use of the bags is to retain mucilaginous matter and other impurities, while the oil rises to the surface, is drawn off, strained, and bottled. But oil prepared in this way, is only fit for lubrication, illumination, &c., not for medicinal purposes. The

preparation by expression is far superior. The first requisite is to get rid of the hard skin. On a small scale this may be done by pounding gently in a mortar, but it is more conveniently effected by passing the seeds between two rollers, set just at such a distance from each other as to break the skin, though sometimes the seeds are allowed to be slightly crushed. The seeds are cleaned by winnowing, and carefully picking over. The details of the further processes differ very much, but there are two principal plans of procedure. In India, a plan somewhat like the following is employed. The cleaned seeds are put into hempen bags, and pressed in moulds into the shape of bricks. The bricks are placed in layers in a hydraulic press, each layer being separated by a sheet of iron heated to 90°. The pressure is applied gradually, and the oil thus obtained is of the first quality. The crushed mass is again subjected to pressure with the plates heated at 100°. This gives a second quality of oil. After standing for some time, a sediment is deposited, the oil is drawn off, and filtered through flannel bags. Another system, which is preferred in California, is as follows:—The shelled seeds are placed in a shallow iron reservoir, and submitted to a gentle dry heat, not greater than can be borne by the hand. They are then put into a screw-press, which may be worked by horse power. The liquid which comes away is boiled for one hour with an equal amount of water. The clear oil is removed next morning, and again boiled with a small quantity of water. "At the exact point when the water has all boiled away, which is indicated by the bubbles ceasing to rise, the process is stopped, as every care must be taken not to push the heat too far." The oil is sometimes bleached by placing it in tanks or large glass vessels, and exposing it to the sun. It loses some of its purgative power, but nevertheless obtains a higher price in the market.—*Jamaica Bulletin.*

TEA PLUCKING AND PRICES.

Men pluck in April, medium pluck, at the rate of 400 lb. per acre; in May, medium fine, at the rate of 300 lb. per acre, and then they say oh! the loss is only 33 per cent. How are they to judge this? If they had continued medium plucking in May, they most likely would have got 400 lb. per acre, so the correct loss is 50 per cent. Further on you state that by plucking fine they get the same quantity of Broken Pekoe and Pekoe as before without the Souchong. No, they do not; they get less. The Broken Pekoe and Pekoe are increased (particularly the Broken Pekoe) by a considerable amount of Souchong ground down in rolling, which nosifting can take out. This increases the quantity of the Pekoe and Broken Pekoe, so, if Broken Pekoe and Pekoe are plucked separate, there will be quite $\frac{1}{2}$ less of these teas, but they will be finer teas and will fetch a slightly (?) higher price, not enough, I am afraid to compensate for the loss of the Souchong and Broken Tea, and also for the loss in quantity in the Broken Pekoe and Pekoe plucked by themselves.

What you state as to these teas going into the market by themselves, etc., is perfectly correct. As far as I can see, what has been written so far on this subject are mere assertions, not facts—which are not easily arrived at. One man states that by plucking two leaves and bud every eight days you will get more than, or as much as, plucking three leaves and bud every ten or twelve days, as the tea will flush faster from the young third leaf left than from the mature fourth leaf left in the coarser plucking, and that by plucking finer you will lose no quantity and gain quality and price with the finest tea. I should very much like to know how this is proved? By simply taking one month's or season's yield with another is no proof, as I have stated before. When the idea was started in Ceylon to leave the whole-leaf and fish leaf, instead of $\frac{1}{2}$ -leaf and fish leaf, it was stated that the flush would be longer in coming from the whole-leaf bud than from the $\frac{1}{2}$ -leaf bud, though most likely the tree would be healthier and stronger with a whole leaf left, but loss would occur by delay of flush. Now to prove this I selected some trees, plucked part with $\frac{1}{2}$ -leaf, part with whole-leaf, took date &c., and then took date of flush coming from each

and when plucked. I found, as a rule, that the whole leaf flush was seven to ten days earlier than the $\frac{1}{2}$ -leaf flush, as I expected, as the whole leaf shoot was stronger, and therefore, sent up its shoot quicker—not only that, but a far stronger and healthier one. So much for assertions vs. fact.

Now, as to the medium plucking vs. medium fine and fine, I have taken the trouble to pluck myself a number of three-leaf shoots and buds, leaving the one whole leaf and mattie. I have weighed the whole lot, then taken off each grade and weighed them, and then taken their percentage, which I give below. This nearly gives the proportions of each kind of plucking, though too favorable for the fine teas, as the finer leaves, of course, are rather stronger than if plucked before they had the four leaves below them; at the same time, I think, it gives as close a proportion as we can get. I have divided the grades in the middle of the stem between each grade of leaf as the only way to get a correct proportion.

	lb.	per cent.
Medium plucking, say	400	per acre or 100
Third leaf thrown away	181	do 45.4
Two leaves and bud ...	219	do 54.6
	400	100.0

One leaf and bud ... 90 22.7

Of course, someone else may arrive at slightly different percentages, but this is fairly correct.

Or grade of per cent.

Three leaf ...	45.4	} This gives the exact proportions of each part, and comes to the same thing as above.
Two leaf ...	31.9	
One leaf and bud ...	22.7	
	100.0	

In practice, if only the two leaves and bud are taken they will be finer, so it is not likely that 219 lb. per acre will be received—maybe only 200 lb. or less. Also I expect with one leaf and bud it will be less than 90 lb.

What I want to know is what effect plucking, say one leaf and bud, leaving one leaf on shoot would have on the tree and on the coming flush, also two leaves and bud, leaving one &c.; what effect this would have on the shoot from the left leaf; and if the shoot that comes from the fourth leaf in the medium plucking will not be a healthier and stronger shoot, as it comes from riper wood. We want this all *in facts* as far as we can get them. One says plucking fine hurts the tree another "oh no, you get a quicker flush as it comes from more sappy wood." I myself say that three leaves and a bud is best for the tree, best for returns, and best for Ceylon. At the present time if well made (and a fair time from pruning) tea can be made from it, even with the present market rates, to sell at 40 cts. per lb. As to the question, which will pay best, 5 to 600 lb. tea at 40 cts. or 80 to 100 lb. at 75 cts. to R1?—this I leave to be answered.—ENQUIRER.—Local "Times."

SCALE ON TEA.

(From *Proceedings of the Agricultural and Horticultural Society of India.*)

Some specimens of tea plant affected with scale were received from Messrs. Doss & Company of 6, Mission Row, with the following letter:—Dear Sir,—"Mr. Richard Ballard, Manager, Nassau Tea Co., Ltd., Kangra Valley, has sent us the accompanying tin box containing cuttings from his Tea bushes affected with a certain disease, the nature of which is quite unknown to him. We sent the box to Messrs. W. Moran & Co., and they have referred us to you, who could let us know the nature, character, and origin of the disease, as well as its remedy. We should be greatly obliged by your giving us the necessary information, and are prepared to pay any fee you may charge for doing so."

No charge is made by the Society for information on such subjects, and the following reply was sent:—"Referring to your letter of yesterday's date forwarding a box of tea prunings affected with disease, and asking its nature and a remedy. The tea is affected or attacked by Scale insects, and I will ascertain and let you know the correct name for this species. As regards a remedy; if only one or two

bushes are affected, probably the best thing to do would be to cut them down and burn them on the spot, but if any larger area is attacked, the remedy used in America, where the scale bug is a great pest to orange trees, is cheap and safe to apply. An emulsion is made with Kerosine, soap, and water or Kerosine, milk, and water; these are churned till butter is formed, which is mixed in certain proportions with larger quantities of water and sprayed on the plants effected through a peculiar-shaped nozzle. Full particulars were published in our Journal, Vol. VII, Parts II and III (1884 and 1885). If you propose using the remedies, I will be happy to give further details, and can lend you a nozzle. I can also give you a wash prepared in England for use against such insects. A small hand pump would have to be provided. If you propose trying the remedies suggested, perhaps one of your assistants may be able to call, when I will be happy to explain the practice to him."

Mr. Cotes of the Indian Museum was asked to identify the Scale insects, and in reply to the reference made to him, wrote, the twigs "sent were covered with Scale bugs (*coccide*), which can almost certainly be cleared off without injury to the bushes, by properly applied Kerosine emulsions, *vide* pamphlet enclosed." The pamphlet kindly sent by Mr. Cotes gives a short account of the various insecticides in use, and includes the preparations of Kerosine referred to above as already published in the Society's Journal.

Messrs. Doss & Co. communicated with Mr. Ballard, who replied that some 80 bushes of tea were attacked, and that he would be glad to avail himself of the Society's offer. Some of the wash received in 1886 from the Horticultural and Agricultural Chemical Company, then of Tunbridge, Kent, but now of Glasgow, particulars regarding which will be found in the Societies Proceedings for September 1886 and January 1888, and a cyclone nozzle, were handed to Messrs. Doss & Co., together with further instructions as to the preparations of the Kerosine Emulsion. The cyclone nozzle was made in Calcutta on the description given in the Report of the Agricultural Department of Washington already referred to. It is the invention of an officer of that Department, Mr. Riley, and is not patented: it should properly be known as the "Riley" nozzle.

The February number of "Insect Life" published by that Department, has an article on Insecticide appliances, illustrated by cuts; and shows among others the Riley nozzle. The one made for the Society according to the description published in 1883, is quite correct in all particulars.

Messrs. Doss & Co. sent a Riley nozzle and hand pump for inspection, before forwarding to Mr. Ballard for trial on the Scale which had attacked his tea. The nozzle was made from the Society's pattern, and the apparatus was found to work well. No report has yet been received as to the effects of the wash on the Scale.

Cotton Seed.—From Mr. J. Cameron, Bangalore, asking if seed of good varieties of cotton can be supplied for experimental cultivation by the Government of Mysore. A pound and a half each of imported Sea Island, and New Orleans seed was supplied, and an offer made to arrange for seeds of the different kinds of Indian cotton commercially recognized.

CACAO: PLANTING AND CURING.

(From the *Jamaica Bulletin*.)

SITUATION.—Mr. Morris in "Cacao; how to grow and how to cure it," gives it as his opinion that "Cacao to be successfully cultivated in Jamaica, must be confined for the most part to our moister valleys and hollows. Where the plains meet the hills, at elevations say 150 to 500 feet, and, where there is good shelter from prevailing winds, Cacao should thrive well. . . . The rainfall should not be below an average of 60 inches per annum, nor should the mean annual temperature be below 75° F."

SOIL.—The soil should be rich and moist, and more important still, should be deep, for the tap-root is long,

and if it reaches rock or clay, the tree dies off. A soil with a certain amount of lime or marl is to be preferred.

NURSERIES.—When seed is very plentiful, it is sometimes the custom to sow 2 or 3 seeds together in each hole and when the plants are from 4 to 7 months old to pull up the weakest, leaving only one at each spot.

It is a better plan, however, to sow the seeds first in a nursery, and then plant out with the first rains. If the number is small, the seeds may be sown in bamboo pots which can be readily slit, when taken out into the field. If beds are used, they should be about 20 feet long by 3 feet wide, somewhat raised and composed of leaf-mould or friable loam shaded with Palm leaves or thatch. The plants should be transferred to the Oacao-walk when they are from 6 to 8 inches high.

PLANTING.—The young Cacao-plants are placed at intervals of about 13 feet apart every way. Between every 2 Cacao-plants, a banana must be planted to afford shade for the first 2 or 3 years; and at intervals of 39 feet, trees are grown for the sake of permanent sheds when the bananas are cut down. It is also necessary for the first few months to grow such plants as cassava, chillies, or gungo peas, close to the seedlings. It is well to have all these various kinds of shade plants put into the ground before, or at any rate at the same time as, the Cacao. For permanent shade, such trees as the Sandbox Tree, the Jac-Tree, the Guango, and the Hog Plum are recommended.

CURING.—The Cacao exported from Jamaica obtains a price so far below Trinidad Cacao, that it was determined to make some experiments in curing, in order to be sure that the low price was due, not to bad seed, but to bad curing. The first experiment consisted in curing mainly according to the directions given in Mr. Morris's pamphlet. The beans were taken from the pod, and placed to ferment in a barrel with holes in the bottom through which the moisture drained out. The temperature never rose above 92° F, and remained for some days at that point. After 6 days, the beans were taken out, and spread in the sun in a thin layer, women being employed to rub them occasionally between their hands, and remove the refuse. They were turned over at intervals to prevent scorching, and were shaded during the middle of the day when the sun was at its hottest. At night they were placed in a heap in the store-room. Not a drop of rain was allowed to touch them, and they were not washed. After about 6 days, the beans break easily, and if properly cured, should be of a good chocolate colour without any white skin between the component parts, of a vinous smell, and a sweet (not bitter) taste. Half of the beans were clayed with red clay, but this operation made no difference in the final result, and is evidently useless. The cured beans were shown to Mr. Bravo, a manufacturer of Chocolate in King St., Kingston, and he pronounced them equal to Trinidad for his purpose. It is strange that he should have to import Cacao from Venezuela, and Trinidad, and pay the duty because he cannot get native Cacao properly cured.

Taking a hint from Mr. Bravo, another experiment was made, which varied from the first in the following point:—The beans were not taken out of the pods, and placed in a barrel, but the pods were simply cut in half, and thrown into a heap with plenty of banana leaves over them. The temperature rose gradually from 92° on the first day to 106° on the sixth. Mr. Bravo pronounced this sample to be better than the first, very much like some Trinidad, but inferior to some samples from Venezuela. Only experience can determine exactly the best conditions necessary for first class curing, but these experiments show that by the method of washing and simply drying the beans without any fermentation, our settlers are just throwing money away. The beans are good enough, it is the want of curing which produces the inferior chocolate. These results are due to the careful way in which the experiments were carried out by Mr. Harris, the Superintendent of Hope Gardens. It would help settlers very much if the clergy, school teachers, and other, interested, would try to impress on their minds the following few directions for curing Cacao:—Never let a drop of rain or water touch the beans. Never wash them. Cut the pods in two, and pile them in

a room or shed in a heap with plenty of banana or plantain leaves over them. After from 4 to 6 days, spread them out in a thin layer in the sun. In the middle of the day when the sun is too strong, shade them. Turn them over now and then, rub between the hands, and pick out the trash. After 4 or 5 days the beans will be cured, if they break easily; if the colour is dark chocolate, not red; if there is no white skin inside; if it tastes sweet, not bitter.

NEW ZEALAND FLAX.

This most useful fibre-producing plant wherever tying, bundling, and hauling have to be done, has, I notice, and will continue, I am confident, to be the subject of continuous discussion. Your correspondent "R. A." is making inquiry about it at the present time (p. 200, August 17, 1889), and others will follow suit. Fibre-producing plants are and will continue to be in request; the textile characteristics of this, in particular, make it the subject of attention on the part of those who are interested in the manufacture of cordage and textile fabrics, in their great variety of forms and innumerable uses.

Experience proves your opinion to be well founded as to its not being a remunerative crop to grow for manufacturing purposes. The difficulties attending cleansing the fibre are not so great as is generally supposed; boiling it in water removes the gluten; careful combing makes it soft and pliable. I dare say especial machinery may be requisite for the preparation of large quantities economically, and, when prepared, it is not comparable to Hemp for durability, although in a fresh or half-dried state it is the stronger fibre of the two, and will bear the greater strain. It will not bear exposure, and is subject to decay, when it is so friable that it is easily broken. Ropes manufactured from it, subject to alternating heat and moisture, cannot be depended upon after they have been in use for a short time.

But it is not as a textile or manufacturing plant that I regard it as most useful. I am a practical gardener and farmer. It is more as an useful and necessary plant on the farm and garden that I regard it. Manufacturers will, of course, look at it from a different and equally legitimate point of view, and I trust they may realise their hopes and wishes.

Grown in a moderately rich soil, damp in preference, *Phormium tenax* produces leaves from 3 to 6 feet long, which may be cut for use at any period of their growth. These leaves may be stripped in bands as long and as strong as may be required, and are useful for tying plants, trees, vegetables, Wheat, Hay, faggots, &c.; I use them for all these purposes, and find it very convenient to have them always at command.

The plants are hardy, resisting many degrees of frost without injury. The old leaves do not suffer if allowed sufficient room and air to prevent excessive moisture from hanging about them during the winter months, which causes them to rot.

Compared with Russian matting and raffia, the leaves and ties are stronger and more economical in use, as there is less waste. It is self-evident that it is cheaper to grow than to buy; and a perch of ground devoted to the purpose produces a large supply, and lasts many years when established.

It is easily propagated, either from seed or the division of the crowns. The plants, in a young state, require care, but when sufficiently strong for planting out, they grow rapidly. The plants are impatient of removal, and should be planted in some spare corner, avoiding the drip of trees. It grows quite as freely in the shade as when fully exposed. I forward you specimens of the green leaf and the dressed fibre.

—C. B. S., Jersey.—*Gardeners' Chronicle*.

CINCHONA AND QUININE PRODUCTION IN INDIA.

In a blue book just issued, giving various statistics to exhibit the material progress and condition of India during the year 1887-88, the section devoted to agriculture contains some information respecting cinchona

cultivation and its results. It appears that the area then under cinchona in the Government plantations of the Darjeeling district in Bengal was 2208 acres, on which were growing 4,851,000 cinchona trees in permanent plantations. It is stated that more than one-half of these trees belonged to the calisaya or quinine yielding variety, and during the year 424,000 trees of this variety were planted out. The proportion of succirubra trees is also stated to be more than one-half of the above number, so that there is evidently some inaccuracy in one or other of these statements. The number of succirubra trees uprooted for their bark was 375,000. The total crop of bark obtained was 290,000 lb. in a dry state. The whole of that supply, with the exception of 855 lb., was made over to the factory, which manufactured from it 331 lb. of quinine sulphate and 6916 lb. of cinchona febrifuge. Taking the yield of quinine sulphate from succirubra bark at 1.5 per cent., the quantity consumed for producing the quantity above mentioned would be 22,066 lb., leaving 267,079 lb. for the cinchona febrifuge, the yield of which would thus amount to about 2.5 per cent. of the bark used. That would be but a poor yield for good succirubra bark, and if it represents the actual contents of alkaloid, the bark must have been of poor average quality. The cost of the plantations is stated to have been 76,700 rupees, but that was irrespective of interest on capital. The money yield of the factory at the rate of 14 rupees per pound for febrifuge and 20½ rupees per pound for quinine was during the year 137,510 rupees on the products issued to the Government department and to the public; but some part of that supply appears to have been drawn from the produce of the previous year, since it was larger than the total quantity of products manufactured, while there was also at the end of the year a stock of bark, more than half calisaya, amounting to 296,000 lb. It is difficult, therefore, in the absence of further data to arrive at any estimate of the actual relation of the cost of production and return realised.

Mention is made of a new method of manufacturing quinine by steeping the powdered bark in cold oil as having been perfected during the year, and it is said to yield a "particularly good quinine," but no data are given by means of which an idea can be arrived at as to the cost of this method and its efficiency for the extraction of the alkaloid from the bark. It may, however, be pointed out that the price above quoted for quinine sulphate of 20½ rupees per pound would make the quinine about double the price that this article has been sold for in England and America during the last few months. That also is taking the rupee as being equal to only one shilling and sixpence, and so far there does not appear to be any great advantage in the production of quinine sulphate in India.

The area under cinchona in the Government plantations of the Nilgiri district in Madras is stated to be 908 acres, on which were growing 1,740,000 cinchona trees in permanent plantations. This is a smaller number by 198,000 than was returned in the report of the previous year, as part of one plantation had been abandoned and the trees uprooted. The crop for the year amounted to 93,000 lb. of dry bark, of which 7000 lb. was issued and the remainder stored, making the total quantity in stock at the end of the year 251,000 lb. It is the intention to convert this bark into quinine sulphate and cinchona febrifuge, on the plan that has been adopted in the Bengal plantations, and buildings with machinery for that purpose are being erected. The outlay on the plantations during the year is stated to have been 72,160 rupees, but in respect to return, it is merely stated that the 7000 lb. of bark issued was valued at 1200 rupees. Here again there are no data for any estimate of the relation between cost and return.

The area under cinchona on private plantations is returned at 1355 acres in Bengal, 6444 acres in Madras, and about 2000 acres in Coorg and Mysore. The export of cinchona bark from India has risen from 1,286,900 lb. in 1886-87 to 1,449,313 lb. in 1887-88, and to 3,074,098 lb. in 1888-89.—*Pharmaceutical Journal*.

THE CHALLENGE OF "A TAMIL CULTIVATOR" ACCEPTED.

Colombo, 22nd June, 1889.

TO THE EDITOR OF THE CEYLON "EXAMINER."

Sir,—I have perused the letter signed by a "Tamil Cultivator" challenging Mr. Elliott and myself to cultivate 25 to 50 acres of four kinds of paddy land which he says he will supply at a rental of 3½ bushels per acre,

As the results given by Mr. Elliott were the results of the cultivation of two of my men, I feel that it is I who should accept the challenge, and I accept it for a total of 100 acres on the following conditions:—

1. That "Tamil Cultivator" writes in his own name.

2. That the land which he gives me on rent of 3½ bushels per acre is land which has been regularly cultivated for paddy up to date.

My mission is to improve the cultivation, and consequently the food supply, of small Native paddy growers, not to open up new lands for large land owners, such as "Tamil Cultivator" evidently is;—they can afford to do it for themselves.

3. That the lands given are so situated that I can arrange easily for sufficient labour and supervision from Puliyantivu. It must be remembered that I am heavily handicapped by residence in Colombo.

There is no doubt whatever that, wherever my system of Paddy growing is faithfully followed, it will pay a Native cultivator handsomely. I have been making experiments, not once or twice, but for the last five years, and I say only what I know. But I have always been doubtful whether it will pay a European, who is charged for labour rates which are not dreamed by a Native Proprietor, and whose crops are looked upon as a licensed grazing ground for the stray village buffaloes with little let or hindrance from unsympathetic surroundings. I hope "Tamil Cultivator" will see that I am fairly treated on these points, as my acceptance of his challenge is purely on public grounds, and will give me a good deal of trouble and inconvenience owing to my inability to supervise the cultivation myself.—I am, Sir, Your obedient Servant, H. W. GREEN. D. P. I.—Local "Examiner."

COCONUT LEAF DISEASE.

By the same mail that brought the *Examiner*, in which the opinion was expressed that the sooner Government took official cognisance of the Coconut Leaf Disease the better, I received a letter from Mr. Potter, confirmatory of that opinion. I look upon it as more than a coincidence. It will be remembered that when the disease first appeared and I drew official and public attention to it, Dr. Trimen and Mr. Jardine inclined to the belief that the discoloration on the leaf was due to insect attack, in opposition to my belief that the discoloration was due to a fungus. When Mr. Potter visited the Estate from which I write, he was inclined to share in my belief, and told me he had shown the leaves I sent Dr. Trimen to some German Botanists and they pronounced the disease fungoid. To further satisfy himself, he took affected leaves with him to Cambridge, and promised to submit them to Mr. Marshall Ward the Mycologist, who investigated the Coffee leaf disease. His letter does not show he has done it yet.

I have repeatedly drawn attention to the fact that there have been several kinds of "disease" that have affected the palm since I first drew attention to the subject. The latest form of it left no doubt on my unscientific mind that the attack was fungoid. It consisted of a rust like (oxide of iron) discoloration on the upper surface of the leaf. At present there are apparently several kinds of fungi-attacking coconut leaves.

Herewith Mr. Potter's letter:—

"University Herbarium, Cambridge, 4th July, 1889.

I am very sorry I have not been able to write to you before, but my work on return home has occupied all my attention. I have at last been able to work at the Coconut leaf disease, but not thoroughly; and I find that there is a parasitic fungus most likely a *Phragmidium*, a fungus allied to one which lives upon the wheat in Europe (namely *Æcidium Berberidis*). We have in Europe many species of *Phragmidium*, all parasitic, upon various plants, but these being wild the fungus does no harm. I am sorry at present I have no practical remedy to suggest. If all infected leaves could be burnt, it would destroy the disease. This is the only remedy I can think of. Sulphur and lime, carbolic acid, &c., were all tried on the Coffee disease, but with little or no effect.

"Considering the importance of the Coconut palm to Ceylon, I should think the question is a serious one, and should be looked to at once; and that the attention of the Ceylon Government should be drawn to it. I shall be glad if you will write to me any particulars that may come to your notice—for instance is the disease spreading in Ceylon? One would fancy it would spread during the damp weather.

"Some species of *Phragmidium* here live on two separate plants, passing one stage on one plant, and then the other stage on another plant. So that if this were the case with the Coconut disease, and one could only find the second plant, some good might perhaps be done by its total destruction. This would be a hard piece of work to investigate, and then, no doubt, the fungus could live for several generations, on either plant.

"I hope very soon to be able to send you more particulars about the Coconut disease, and intend to write a small paper upon it. This I will send as soon as I can.

"Could you tell me if the disease is present on the Coconuts growing by the sea side?"

It will be observed that Mr. Potter does not identify the fungus. He says it resembles one allied to that which attacks wheat. One cannot wonder that he suggests no remedy for it. It is obviously out of his province, and though I lay no claim to an intimate acquaintance with the present history of all the enemies of crops in Europe, I do not think an effectual remedy has as yet been discovered for fungoid attacks. I shall be glad to be corrected. Burning the affected leaves is rather a heroic remedy, and can be carried on, without irremediably injuring the palm, only if continuous wet weather follows. Even then the shock to the plant will be great, for unlike small trees and shrubs, the Coconut palm does not clothe itself with leaves as fast as they are removed. One leaf per month is, I believe, the average. Without a proper complement of leaves, the lungs and stomach of the tree, the health of the palm must inevitably suffer. What we ought to be able to find out, and that by the help of the Government, is not so much a remedy for, as the cause of, the disease. Remove that, if it be possible, and the battle is won.

The reply to Mr. Potter's enquiry, whether the disease is spreading, is that it undoubtedly is. I have seen it all along the Railway line as far as Kandy. I have seen it all along the road from Vevangoda to Negombo, and at the latter place on highly cultivated Estates which were at one time reported to be free of the disease. I have seen it in Colombo, Heratgoda, Ambepussa, and in the heart of the Hapitigam Korale. It has been reported as existing at Wellawatte on the sea coast and at Batticaloa. I have no doubt it is present everywhere that coconuts are cultivated, only that those engaged in its cultivation think that by keeping the matter secret and to themselves, they are safeguarding their interests most effectually. It would be well if all those interested in Coconut cultivation boldly face the fact that a disease that may prove serious is affecting their trees, and unitedly ask the Government that a Specialist be appointed to investigate it and find out how it may best be combated. He may be able to

find out whether during one stage of its existence it does leave the Coconut tree, the tree it passes this stage of its existence on and during what period of the year, so that we might combat the fungus then. I am sure all interested in the question will be glad of more particulars from Mr. Potter and for a perusal of his paper. I shall make both public.

And now I wish to address myself to Mr. Driberg, the Principal of the School of Agriculture, who, I suppose, is still investigating the disease, and who I expect will shortly favour us with a full report on the subject. In his preliminary report he says, "I have no hesitation in saying that thorough cultivation is the surest way of combating the evil." He has just returned to the Island after a prolonged course of theoretical and practical training in Agriculture in Europe, and will be able to tell us authoritatively whether "thorough cultivation" has helped European Agriculturists to successfully combat the diseases that attack crops there. I read somewhere some time ago that experiments had proved that the Potato disease was due to a deficiency of Potash in the soil, and that it disappeared with a free use of Potash. Is this so? Has not experience proved that in a flinty soil and also in one in which limestone abounds, rust is very nearly absent in wheat? If this be so, it may support the theory I started at the very beginning that the Coconut leaf disease may be due to a deficiency of some plant food in the soil. It may be salt, or it may be something else. Analysis ought to settle that, or else why the disease is more virulent in certain areas than in others?

With reference to Mr. Potter's statement that some species of *Phragmidium* pass different stages of their life on different plants, I came across a confirmation of this accidentally in the first volume of the *Tropical Agriculturist*. Professor Buchanan denounced as a popular error the belief of peasants that the berberry tree was the cause of rust in wheat. He said that the peculiarity in the colour of the rust in wheat and of the fungus that attacked the berberry was at the bottom of the belief, but that no connection has been traced between them. Oersted and de Bray discovered that they were alternating generations, of the same species. Sachs and Prantl found out that the uredo-spores of the rust in wheat are red. In the Autumn black telento-spores appear, then germinate exclusively on the berberry in the following Spring, and the cycle is completed by the appearance of uredo-spores with a mycelium on grasses. Rust of wheat requires an alternation of host plants to complete the cycle of its life history. It was supposed that the destruction of the berberry would not exterminate the rust, "for fungal parasites have a wonderful power of adapting themselves to surrounding conditions, and a new alternating host plant might gradually be brought into use. "Fungal spores being excessively minute are transported by the wind, and a wheat field may get rusted very many miles from the neighbourhood of berberry plants.

At the time Coconut leaf disease attracts attention, I noticed fungoid attacks on very many plants, and I brought them to Mr. Potter's notice. If I mistake not, he took away with him other leaves than Coconut. The wild bread-fruit, wild-fig, cinnamon, and other trees had attacks on the upper surfaces of their leaves very like the rust-like spots now to be seen on the upper surface of Coconut leaves. Could these be the alternating hosts of the Fungus? Here is an interesting study for Mr. Driberg.—B.—Local "Examiner."

THE BLACKMAN SYSTEM OF WITHERING.

(By THE "PERIPATETIC PLANTER.")

(From the *Indian Planters' Gazette*, Oct. 29th.)

The following particulars about the Blackman system of withering, which I have gleaned from Mr. Skinner of Silcoorie, in an interview, may be of use and interest to a good many. At Silcoorie, there is more than an ordinary amount of heat developed in

the manufacturing room below the withering floor; as the Blackman system has enabled him to concentrate the manufacture from outlying gardens, all at Silcoorie. Under these circumstances less fan-power is required than under ordinary conditions, as the warmer the air, the more absorbent it is, and *vice versa*. Hence, the cooler the air to be employed, the more air is required, and consequently the more fan-power to supply and remove it, rapidly. The length of the Silcoorie house is about 100 feet and the width 45 feet, there being a lean-to roof over an annex the full length of the house and about 20 feet wide. He employs four rows of withering shelves down the whole length of the main building and three down the annex. The "shelves" are only about 2 feet wide, and are those known as Main's being metallic. They are about 17 deep in each row. Hence in each row we have $17 \times 2 \times 100 = 3,400$ square feet, or in the 7 rows 23,800 square feet of surface. The method adopted is, to place the leaf, when brought in, in a godown sometimes a foot or so deep, and draw it from thence as required to fill the shelves, and be withered. It will surprise a good many to learn that with only this 23,800 square feet of surface, 150 to 200 maunds of green leaf can be easily withered in the wettest of weather in ample time to allow of the rolling and firing being all completed, and the tea-house closed for the night at 5 o'clock in the evening, or 10 hours from starting? The *chû bungalow shib's* lot will not be such a bad one in the near future as it sometimes has been, it is clear. Mr. Skinner does not know what night-work is, save as a night-mare of the past. All the fatigue, and harrassment, all the loss which is so unavoidable when night work is required, are things of the primitive past to him. His fans, three in number, are erected equally distant, in the partition between the withering floor of the main-building and the lean-to annex. At the opp site side of the withering floor to the fan-side, there is a slit in the floor, the whole length of the building. The warm air from the driers below is *sucked* up through this slit, passes through all 4 rows of withering shelves, to the fans, and is *blown* down into and through the tea on the shelves in the annex, (after passing through the fans,) and then out into the open air through the two open ends of the annex. Just below each fan is a shield about 6 feet wide, consisting of small bamboos laid horizontally between the roof of the annex and the main-wall, the bamboos being 1½ to 2 inches apart; this shield suffices to distribute and break the direct force of the blast, so no leaf is blown off the shelves immediately below the fans. Mr. Skinner prefers this arrangement of the fans, to placing them at one end of the building, and drawing the air so far. The air has less distance to travel, and is consequently more even in its absorbing power, as it is not saturated *en route* before it has been made to do all its work. Further, there is no risk of blowing any leaf off the shelves, if the shields are properly erected. With his three fans (48-inch) he has found with this comparatively trifling withering surface no difficulty in turning out 640,000lb of made tea in a season and could have easily done more! Compare the cost of the upkeep of such a small house as is thus required with the upkeep of the roofing, &c., required under the old system,—and that saving should pay for the fans in one season. Then, the gain in quality, by uniformly successful withering in all weathers, and the absence of loss due to night work, become small profit. I am only trying to repeat Mr. Skinner's own words as nearly as I can recollect them. He has, as I have said, 3 fans at present, but thinks that he could still further hasten matters by having a fourth. The fans, he says, to draw across a house 45 feet wide, with four rows of obstructing shelves *en route*, will succeed capitally when set not more than 20 feet apart, having due regard to the important factor, that the colder the air used, the more of it must be passed over the the leaf. By making the only *exits* for the air, the two ends of the annex, the leaf in the annex gets the whole benefit of the current, and the air, as it leaves the ends of the annex, after doing its work, is still absorbent enough to dry wet clothes rapidly. The

walls of the withering-floor are not perfectly air-tight and where there is a crevice or crack, the air, answering to the suction of the fans, can be felt blowing in; but these defects make no apparent effect upon the withering; as the fans are superior to such trifles.

[Will Ceylon planters who have tried the Blackman Fan for withering kindly favour us with the results? The account above given is most interesting and seems important. But what a revolution has taken place in the ideas of tea cure, since we were told that we must make provision of space for withering tea slowly by cool atmospheric air.—Ed. T. A.]

SOWING AND GERMINATION OF SEEDS.

(From the Jamaica Bulletin)

No hard and fast rule can be laid down for sowing seeds. Small ones are, as a rule sown thickly while large seeds are planted singly and at some distance apart. Then, again, large seeds require to be covered rather thickly with soil, while small seeds need only be very lightly covered.

Germination is the first act of vitality in plants. The quantity of moisture necessary to enable the seed to germinate varies with the nature of the plant. Seeds of water plants should be entirely immersed, but those of land plants need only be kept moist, and it is essential to germination that they should be kept moist, for if allowed to become dry they shrivel (except of course hard coated seeds like some palm seeds) and the germ loses its vitality. If seeds get too much water on the other hand (except water plants) they undergo a kind of maceration which destroys their germinative power. The atmosphere should have free access to the seeds, hence the soil should be light and open. Seeds buried in stiff clay, or at considerable depths below the surface do not germinate. All seeds do not take the same time to germinate, beans and peas for instance germinate very rapidly, while some of the palms, Ceara rubber, &c., often take years before showing any signs of growth.

The soil used for covering seeds should always where practicable, be sifted. Where a large quantity of small seed is sown, *e. g.* tobacco seed, it will answer the purpose if, after the seed is sown, the beds are lightly raked over so as to cover the seeds. Very small seeds need not be covered at all, but immediately after sowing they should be watered and the water will carry them down a sufficient depth for all their requirements. It is always safer to sow small and delicate seeds in boxes or pots, but it is of great importance that these should be thoroughly drained. The boxes or pots may be covered with glass which will prevent excessive evaporation and will keep the atmosphere in them in a state conducive to germination. The glass should be removed as soon as the young plants appear or they will be "drawn" by it, and will become weak and straggly.

Ants are very fond of some small seeds and in a short time will carry away every seed out of a box. To put a stop to the depredations of these mischievous little creatures a good plan is to have a stand made with for legs, large enough to hold one or two seeds boxes, and either have the legs tarred, or ants each in a small tin of kerosine oil; this will prevent ants getting at the seeds. I have already mentioned that all seeds do not take the same time to germinate, some taking a few days, and others years. It is not desirable that we should have to wait one or two years for the seeds of a certain plant to grow, and some remedy to prevent this long delay, or rather some remedy to promote and assist germination is usually resorted to. Various remedies have been suggested, but the most effectual is generally admitted to be that of soaking the seeds in water for some time previous to sowing. The water causes the seeds to swell and the tough integuments which enclose the embryo burst. Although soaking seeds to induce germination is a good remedy it is not always an effectual one. I have mentioned that the seeds of the Ceara rubber (*Manihot Glaziovii*) often take years to germinate, and this has been the case although the seeds were soaked in a box, two sides of which were made of perforated zinc, placed in a running stream of water and allowed to remain there for

over two months. The seeds of this tree, however, are exceptionally hard, and recourse was had to filing and grinding down the ends of them. This was rather a tedious and slow process but was fairly successful. The seeds of the Ivory nut Palm (*Phytelephas macrocarpa*) also take a very long time to germinate. Some seeds lose their vitality soon, while others retain it for a long time. Nutmegs, for instance, should be sown when quite fresh; if kept for any length of time the kernel shrinks and will be heard to rattle in the shell if the nut is shaken. When this is the case germination cannot take place and it is useless to sow the nuts. I might mention also that great care should be taken in handling nutmegs when even quite fresh. If roughly shaken the embryo becomes detached and the seed will not grow. Coffee and Cocoa seeds also require to be sown immediately after ripening.

In sowing seeds in beds in the open, as for instance, Cocoa, it is best to sow in small drills 6 or 8 inches apart, and the seeds should not be placed too thickly, so that when the young plants appear they will have sufficient light, air and space to develop. It is the practice in some parts to "plant at stake," as it is called, that is, the ground is loosened and the seed is placed where it is intended that the plant produced by it shall occupy a permanent position. It is a much better plan, however, to raise the plants in beds and transplant when strong enough. If a planter wishes to establish, say, 2,000 nutmegs on his property he cannot possibly give them the same care and attention during their infancy, if the seeds are planted singly over a large area of ground, as if he had all in a seed-bed or nursery under his eye.

W. HARRIS.

COCONUT CULTIVATION.

In his report on the Coconut leaf disease, it will be remembered that Mr. Drieberg advised deep draining on Coconut Estates as a means of overcoming the disease. In reviewing that report I ventured to inquire what system of draining he advised, and whether deep drains cut at right angles to the slope of a hill, especially where the subsoil was gravelly, would not tend to deprive the soil of too much moisture and re-act prejudicially on the coconut tree in seasons of drought. Mr. Drieberg has not thought proper to answer these questions, which is a pity, for his opinion on such an important branch of cultivation will be of great weight. The great interest I have in the subject made me refer to it, in a private communication, to one whose opinion is authoritative, and I am sure he will excuse me if I quote his reply and discuss it publicly. The subject is of public interest, and my chief object in carrying on discussions on agriculture in public, is to induce an interest in the subject by all those engaged in this most important occupation, and who, in the generality of instances, carry on a happy-go-lucky system of cultivation. My authority writes, "In answer to your question whether Coconut trees are better able to withstand drought which grow on well drained lands, I say most emphatically, Yes. This is one of the most important results of drainage. There is the advantage of a reserved supply of moisture which the tree draws in by capillarity, and the resulting advantages of sinking water which you know all about. The necessary chemical operations in the soil cannot go on unless the pores are free to be occupied by air." With due deference to my friend, I think that all the advantage of draining he enumerates have special reference to those branches of agriculture in which European Agriculturists are engaged. I do not for a moment wish it to be understood that I deny that the resulting benefits of draining are of local and not of general application. All I wish to say is that circumstances alter cases, and that because draining is of vital importance in the cultivation of cereals and roots in Europe, which is carried on in swampy land suffering from an excess of moisture, it does not follow that deep drainage is as essential in the cultivation of Coconuts on undulating land, where natural drainage is ever present and where the soil is opened up and aerated to a very great extent

by the deep-feeding roots of the natural herbage and by the still deeper feeding roots of the coconut tree itself. It must not be forgotten that on low-lying flats, where an excess of moisture is ever present, drainage both to raise the level of the land and to get rid of superfluous moisture is resorted to, even by the uneducated villager, whose only knowledge of the benefits of drainage is intuitive. The reference to the necessity of the pores of the soil being free to be occupied by air makes it clear that my friend has in his mind a soil whose pores are occupied by water. The pores of ordinary coconut soils in inland districts are not so occupied, and as nature is said to abhor a vacuum, I think it follows that the pores of such soils are occupied by air.

I believe I mentioned in my review that my system of drainage was to cut shallow contour drains traced as nearly level as possible, and throw the soil on their lower side so as to increase their capacity. I cut my drains from 9 to 12 inches deep, and 6 feet wide. The object with which I drain is primarily to catch as much as possible of the rain-water that falls on the land, to pass it through the soil, and also by imposing frequent barriers across the face of a slope to reduce the volume and the velocity of the water that will otherwise rush along the surface. The benefits I expect to follow these operations are, 1, the aeration of a large surface of the soil by wide drains; 2, the abstraction by the soil of all that is of manurial value in rain water; 3, the storage in the soil of large quantities of water that can be drawn upon for use in seasons of drouth; 4, the passage through the soil of air in the wake of the water; and 5, the absorption of the water that falls on the surface where it falls by the imposition of frequent barriers. I should be glad of an authoritative opinion as to whether this system is faulty, and whether too much is expected from it.

My friend writes further, "The deeper the roots are induced to sink, you will admit that the better the tree is insured against lack of moisture. How could this be done better than by deep cultivation and drainage?" Plants have generally two kinds of roots, laterals and the tap root. The latter makes its appearance with the bursting of the germ and has a downward tendency. The duty of the tap-root is to anchor the plant firmly on the ground. I wish to be informed what the other functions of the tap-root are. I remember having read somewhere long ago that, in addition to the duty it performs as an anchor, it acts as a pump to the tree, and most of the water a tree is supplied with is through the tap-root. Its powers of suction are said to be so great, that in sandy regions trees have been cut down with a hard and almost solid column of sand in their heart and seemingly incorporated with the wood. As the trees had no external injury through which the sand could have found its way inside, and even if injuries did exist it not being possible that the sand could have been found in the state it was argued that it must have been forced up with the water through the tap-root. The coconut tree, in common with all palms I believe, has no tap-root, but it has roots corresponding to it and which from their earliest period of life have a downward tendency. In digging a well in a piece of low-ground not very long ago, I came across these roots 7 and 8 feet below the surface and at water level. I was told by an old and experienced planter that in Jaffna, when digging a tank he came across coconut roots fully 20 ft. below the surface. These roots have a wonderful power of working their way down even in very hard soil. The laterals on the contrary are invariably found at the surface, and seldom go beyond the depth of the surface soil. In a shallow soil the lateral roots of the Coconut tree will all be found at the surface. The reason for this is obvious. From the laterals spring the root hairs or feeding roots, and these instinctively abound where most food is available. What I wish to know is what roots it is intended to drive deeper into the soil by deep drainage? If the roots that correspond to the taproot, I think it will be found that in a Coconut Estate these will have already found their way, except on a very young plantation, beyond the influence of even deep drains. If the lateral roots will by simply increasing the

porosity of a soil induce roots to leave their feeding grounds and seek others where food is not immediately available, for it cannot be pretended that insoluble particles of soil become soluble simultaneously with their contact with air? The process is slow, and the time it occupies depends on the degree of insolubility of the soil if I mistake not.

Against deep tillage I have nothing to say; but of the wisdom of deep draining on land that does not suffer from a superfluity of moisture, and for a product that suffers more from want rather than from excess of moisture, as at present advised I am not convinced. The point at issue between my friend and myself is, whether a shallow or deep drained soil has more available moisture. It must not be thought that the position I have assumed is that of a critic. I am an earnest seeker after knowledge; but my frame of mind is such that I cannot accept anything as a truth till I have fully satisfied myself that it is such.—B.—Local "Examiner."

CEYLON OOLONGS.—Did you see the fine prices I got (or rather my brokers H. A. Hertz & Co.) for a small shipment of oolongs the other day?—bro. pek. 1s 4½d, pek. 1s 5d, pek. sou. 10½d. Who says Ceylon can't make oolongs after this.—Cor.

TEA.—On dit that the Dublin branches of the London and Newcastle Tea Company are arranging to open drug and patent medicine departments in connection with their stores, and with a view of pushing the sale of their Bohea purpose to "cut" the chemists at cost price.—*Chemist and Druggist*, Oct. 26th.

THOUGHTS SUGGESTED BY ARTICLE ON COCONUT DISEASE. "Why is it (the disease) worse this year than it had ever been before?" This question has never been answered with regard to other plant "diseases." It is almost impossible of answer. Wheat rust, Coffee leaf disease, Phylloxera, Potato disease &c. are all new diseases. The words "new diseases" are ominous. The Potato disease was unknown till about 1846. The vine diseases are equally modern. Coffee planting in Ceylon was ruined since 1872. Are we developing new diseases? It looks like it.—*Science Gossip*, Dr. Taylor. Before we call in the aid of a Scientist from England, I think it best to find out with local talent if the parasitic fungi existing on the leaves of other trees are identical with that on Coconut leaves. Specimens of all leaves affected can also be sent to England by Government to settle this point. If Government supply me with small bottles and spirits, I can forward samples to be sent to Kew. Dr. Trimen detected a fungus and not the fungus on decayed leaves. This can be detected by any layman with the naked eye. This fungus is probably one of those bred by decayed vegetable matter. The bug has not been discovered, i.e. the bug Dr. Trimen imagined made the punctures that produced discolouration, but a bug that has nothing to do with the diseased condition of the tree. The fungus that is the cause of the disease has been discovered by Mr. Potter. Mr. Potter does not recommend the application of fire to growing leaves. Its effect will be to destroy their vitality. "If all affected leaves could be burnt" surely does not mean the application of fire to growing leaves. The same remedy was suggested for Coffee leaf disease, and the suggestion was not taken to mean the application of fire to growing leaves. Is burning possible without destruction? With regard to the Kerosine emulsion cure you suggest, Marshall Ward says with regard to a cure for leaf disease: "It must effectually kill the germinal tubes before they enter the leaf and yet must not injure the Coffee. The cure must be capable of rapid and wide diffusion so as to reach every germ. It must be very soluble, so that it may be taken up by the water in which the germ tubes are forming. It must act for a long time and continuously, in order that the later germ tubes may be attacked as they form." The remedy must be applied during wet weather, as it is then that reproduction takes place, and it must be continuous. The "sprayer" might be efficacious.—Cor.—Local "Examiner."

THE WORKING OF INDIAN TEA COMPANIES.

The Calcutta Planters' Stores and Agency have published an analysis of the working and position of some of the leading Indian Tea Companies to end of 1888. The Assam Company, as usual takes first place. The paid up capital of this Company is £187,160 at the rate of £20 per share. This gross price per lb. of tea last year was 1s 7-16th d, the cost having been, including all sale charges 11d. The profit was, therefore, only 1 7-16ths d. The result was that the dividend was only 7 per cent, against 10 for each of the two previous years, with 20 for 1885 and 14 for 1884. The yield was 303 lb. per acre. The Borelli Company with a yield per acre of 531 lb. got only 10½d for their tea and yet made a profit of 2 5-16th d and paid an average dividend of 6½ per cent. The Darjiling Company, with a yield per acre of 312 lb. made a profit of 3 5-16th d and divided 6 per cent. The Doom Dooma Company with the highest yield per acre recorded, 630 lb. made a profit of 2 5-8ths and yielded a dividend of 8 per cent. The most dividend-yielding of all the Companies for years back, the Jorehaut Company with only 274 lb. per acre, and a profit per lb. of only 1 1-16th d, shared a dividend of 10 per cent, against, 15 the previous year, and 18 the year before that. Of course, profits and dividends are affected by capital expended and cost of production. The Eastern Assam Company, with 424 lb. per acre and a profit of 1 1-16th d gave no dividend and has given none for 5 years. The Jokai (Assam) Company, with 434 lb. per acre gave exactly the same dividend as the Jorehaut with only, 274, viz. 10 per cent, the profit per lb. being 2d.—The gross prices in 1888 were generally lower than those of 1877, and so with the profits. There were two exceptions in the latter case, however, the most noted of which was the Luckimpore Company, with 3½d in 1888 against 2 31-32nds in 1887. In the case of 12 out of 14 however, the rate of profit in 1888 was lower, in a few cases markedly so. For instance the British East India Company from 2d down to 0½d, and the Dejee Company 2 1-16th d down to 1 15-16th d. The profit per lb. of the Wilton Company went down from 2½ to 1d, and the dividend, in sympathy was reduced from 10 p.c. to 5. The yield per acre on the 14 estates varied from 630 lb. on the Doom Dooma properties, down to 274 in the case of the Jorehaut estates. The average gross price proceeds sale of crops, including all receipts except gain in exchange, shows the Assam Company with a very steady rate of somewhat over 1s per lb. for five years,—1s 07-16th d in 1888 against 1s 0½d in 1884. The Borelli Company, on the other hand show a serious falling off, from 1s 2 13-16th d in 1884 to 10 3-4th d in 1888. The fall in the case of the Doom Dooma Company is from 1s 03-4th d to 10½d; while the reduction on Wilton Company teas, was from 1s 011-16th d to 9d. The figures are not, on the whole encouraging, except in some cases which show reduction in cost of producing tea. In Ceylon as well as India, planters must endeavour to study economy in this direction, for the competition of India with China and Ceylon with both has seriously reduced prices in the past five years and given consumers what they

desiderate, cheap teas. They are not likely to be willing to give higher prices than they have now been accustomed for some time to pay. So, while we do our best to improve quality and to open new markets, we must endeavour to produce cheaply the teas we are compelled to sell cheaply.

CEYLON TEA IN GERMANY.

Copy.

Address C/o A. Tabor, Esq., 12 Clements Lane, E.C., Lombard Street, London.

Berlin, October 26th, 1889.

L. H. Kelly, Esq., Chairman of the Tea Fund Committee.

Dear Sir,—Having been asked by your Committee to collect information and report on the prospects of introducing Ceylon tea in Germany I have now the pleasure of communicating to you the results of the inquiries I have so far been able to make.

At present the only tea known and asked for all over Germany is China. In only a few instances have I seen Indian and Ceylon advertised, but nowhere have I seen them exposed for sale.

I have sent you five samples of teas which I have purchased at some of the best shops and I have forwarded a duplicate set to Messrs. W. J. & H. Thompson of 38 Mincing Lane, Mr. Thompson having very kindly offered to value and report on them.

The prices of these samples were:—

Marks 4 00 4 00 3 00 2 40 & 2 00 per lb. German

or ½ kilo
= 3/7½d 2/8½d 2/2½d 1/9½d per lb. avoird.

and they were all called souchongs, but the 1/9½ sort, which was dust tea. The prices of teas range from 2s to 8s, 10s and even 12s marks, but the 4 mark 3s 7½d tea is most in demand, as the German, not being a great tea drinker is particularly as to quality and thinks he is likely to get a good tea at 4 mark. How little he really knows what good tea is can be judged from the fact that he considers the large leaf tea to be best, no matter how much red leaf is in it, the size of the tea is to him a guarantee that it is pure and unadulterated. He buys on appearance and not by flavour, his tea must be large, unbroken and well sifted, he does not ask for small tippy teas and looks on them with suspicion as being more capable of adulteration.

I have now been travelling for some weeks all over Central Germany, and in a few days I am going on to Hamburg. I have already had many opportunities of discussing tea with people of almost every class of society, and I have tasted a good ordinary Ceylon pekoe souchong against China tea with many of them, and always with satisfactory results, the Ceylon tea having almost invariably been preferred.

I have, however, not yet distributed any of the tea granted to me, nor incurred any expense on Tea Fund account, nor do I consider it would be advisable to do so, until I have made satisfactory arrangements for a regular supply of pure Ceylon tea, to meet the demand which would arise from a systematic distribution and advertising. In a subsequent letter I hope to submit proposals for the consideration of your Committee or the American Tea Company, as I am now in treaty with a gentleman introduced to me by Mr. Freudenberg, who has recently returned from China and Ceylon, and who is so impressed with the advantage of Ceylon tea that I expect valuable support from him.

In the present state of the tea market, with Ceylon at the top and China at the bottom of the market, there is no chance of the trade doing anything for us, in fact quite the reverse, the cost of advertising it will have to be borne by those most interested in its sale, the growers themselves. I am fully convinced though that this can be profitably done by them, and I am confirmed in this opinion by a gentleman I have recently met here, who undertook the sale of Kangra Valley and Dehra Doon teas some years ago. He was fairly successful for six months, but had to give it up because he could get no support from India for advertising. He anticipates

no difficulty in selling Ceylon tea, because as a self tea it is so much more palatable than Indian teas.

It is perhaps just as well that Ceylon is not in favour or demand, there being no reliable supply on hand, as the trade would undoubtedly palm off their inferior China as Ceylon and so do more harm than good.

If Ceylon tea is to be introduced here with success, it must be judiciously advertised and distributed in packets from depôts where only Ceylon tea is to be had, the packing would have to be done here, as duty in tea at 5½ per lb. is paid on the gross weight less 23 per cent for tare.

I have obtained valuable information from the leading advertising agents, and I am convinced that with their help and that if someone connected with the press Ceylon tea could at a given moment be most extensively and judiciously advertised and at no considerable cost. But once this is done, arrangements for continuing its publicity must also be made.

As regards the consumption of tea, I append statistics showing a slow but steady increase during the last 10 years. I also append the remarks on tea of the Berlin Chamber of Commerce in their report on Berlin trade for 1888.

It will be impossible to convert the Germans from coffee to tea drinking, but everything points to its becoming more and more in vogue. There are certainly only a few shops in the whole country where tea only is sold, but it is exposed for sale in every grocer's window there almost every tenth shop is a colonial produce store. The number of advertisements in the papers is also on the increase, and I am told too that once the quality of tea improves, the demand will also.

Russia sends a good deal of tea into Germany, caravan tea enjoying the same sort of fictitious popularity that Mocha coffee once did. I annex particulars of the duty paid in Russia to show that the tea thus exported to Germany must be of the very worst description, as good tea would not bear the double duty. I reserve further remarks for a subsequent letter, and remain, dear sir, yours faithfully,

(Signed) M. BREMER.

IMPORTS FOR HOME CONSUMPTION FROM 1ST JANUARY 1889

TO 31ST AUGUST 1889.

China ..	521,000	kilos

EXTRACT FROM REPORT OF THE BERLIN CHAMBER OF COMMERCE 1888.

TEA.—The consumption of tea in Berlin this year shows a deficit of 12,874 lb., viz. 1887, 274,814 lb. (Germ) equal to 1'1 lb. avoird., and 1888, 262,000 lb. (Germ), the reason probably being because dealers took advantage of the very low prices ruling at the close 1887 for the lower grades in order to replenish their stocks. The quantity of the recent crop might have been better—only small quantities of really fine Moning Congous came into the market and fetched high prices—medium and ordinary sorts were sufficiently on hand and at moderate prices. It was almost the same with Souchongs. Pekoes were scarce and obtained high prices right through the other grades have no importance for the German market.

The production of tea in India has assumed enormous proportions in the last few years and competes with that of China in a manner not to be underrated. Let us hope the Chinese will be induced thereby to pay more attention to the manufacture of their tea and more especially to cultivate larger quantities of their finer grades.

THE REFORM OF THE TEA DUTIES.

The following letter has been addressed to the editor of our contemporary the "Times," and a proof has been sent to us for publication :—

Sir,—In your leader of October 2nd you base your opposition to the reform of the tea duties on your belief that the existing tariff acts as a differential duty in favor of high as against low-priced teas—*i. e.*, of Ceylon against China growers. If your theory is correct, it follows that the duty is also differential in favor of high against low-class teas grown in Ceylon itself, and differential in favor of high against low-class teas grown on the same estate, to say nothing of the inference that it must further be differential in favor of high-class China teas against low-class Ceylons. But, on the local illustration merely, it appears that some Ceylon estates are "protected" by the duty against others, and that the best parts of the same estate are protected against the worst. This is the logical conclusion to your premises. It is one to which Ceylon planters would be slow to subscribe contentedly, since the quantity of low-grade teas made, even in Ceylon, is largely in excess of the quantity of fine tea made there. If the effect of the duty is differential, as you assert, it must protect only a small portion, comparatively, of each estate against the great bulk of the acreage.

I deny your theory *in toto*. The duty is not differential at all. It does not affect the selling price in bond any more in the case of a China Congou than in that of Hoolankande Orange Pekoe. The grower in either case is equally subjected to the hampering effect of the duty in checking consumption, but neither in the one case nor in the other is the producer one cent the better or the worse, for it is *against his rival producer*. To the retailer's selling price, again the duty makes exactly the same cash difference on the cheap as on the dear tea. In each case the retailer adds to his profit price on the cost of the tea precisely the same amount in order to recoup himself for his payment of duty and for his interest on that payment. There is absolutely no sign of differentiation in the duty.

As to your contention that there has been a satisfactory increase in the home consumption of tea since 1885, I must refer you for my view to a forthcoming number of the *Financial Reformer*. But, assuming that you are right, and that a satisfactory increase in consumption is expressed "in quality," will planters gladly face the prospect of a consumption practically stationary as regards quantity and likely to be still further retarded in quantity by every improvement in quality? It is calculated that soon the 70 or 80 million lb. of China teas now consumed at home will be displaced by Ceylon and Indian teas. *The displacement will be effected by a considerably smaller quantity of the stronger teas.* When it has been achieved, the output of these teas will largely exceed any probable increase in the home consumption under existing conditions, and the disproportion must grow greater day by day. Then, either the price of tea must fall heavily, or else the output must be curtailed. Then, if not before, the Ceylon planters will perceive the absolute necessity of opening a fresh field of consumption in the United Kingdom. There is only one way of opening it up to him in a manner profitable to himself, and that is by the reduction or, better still, by the abolition of the Tea Duties. It cannot be tapped at all, but by a large reduction in retail price. Let the reduction then, fall on the duty and not on the cost price of the Tea. If it fall on the duty, the bond price of the tea and the profit to the planter will be raised. For the evidence of this I must refer you to the proof I gave in my former article, that the lowering of the duty on tea invariably raises the bond price of the article, and must inevitably do so.

You say that there is no fear of the Ceylon planter having to substitute fine for coarse plucking in the event of a fall in price. But are you not writing under the exhilarating stimulus of the high range of prices, particularly for the lower classes of Ceylon Tea, that now prevails? Look back to May and June, and you will find that what you scout as impossible has actually taken place. You will find that the present high prices are to a considerable extent the effect of the curtailment in the supply of low class teas that was forced upon the Ceylon planter by the influence of what I must persist in calling non-paying prices.

Bear in mind that the high price for even Ceylon rubbish* today is the consequence of the low price of Ceylon quality yesterday, and that the high price of today is the antecedent of low price for even quality tomorrow. When the present temporary causes of high price have had their swing, when China tea is quite displaced, when the Australian market, responding to the lowering of the tea duties in Victoria, has glutted itself with Ceylon tea: if then the home tea duties are not reduced or abolished, the Ceylon planter will find that his only chance of making a profit will lie in his making quality only, instead of quality and quantity combined. And with this solatium, that the better the quality of his teas the more difficult he will make it for the general consumption to increase in quantity.

I am not, as you seem to suppose, in favor of the reduction of duty merely. I am heart and soul for the abolition, but I will take the half-loaf as the precursor to the whole.

As to the extent of the fresh field to be opened up the abolition of the duties I would say a word. The home consumption averages about 5 lb. per head. But the consumption of, probably, one-third of the community averages at least 10 to 13 lb. per head. On the lower scale, out of our total annual consumption of about 180,000,000 lb. some 13,000,000 people consume 130,000,000 lb. leaving only 50,000,000

lb to be divided between 27,000,000 heads. That is to say the bulk of the population consume less than 2 lb. per head. They are prevented from consuming more by the dead weight of the duties. Abolish those and the possibilities of expansion in consumption are almost infinite. Remember it is the third class custom that pays best. At present you do not get it.

Consider, too, the impetus that would be given by the abolition to the extra consumption of tea amongst the upper third of the population and, further, the probable growth of a general habit of "waste" in tea drinking. Now, economy in tea use is carefully cultivated. The consumer is forced to economy by an annual bond of £5,000,000. If the bond were cancelled he might treat tea as he does mustard. He takes more mustard than he wants and leaves plenty on his plate. Similarly, the tea-spoonful of tea would be less accurately measured out.

In fairness to myself and my cause I must ask you to publish this letter. C. J. ROWE.

National Liberal Club, Whitehall Place, S. W., October 30th.

[The entire abolition of the duty we consider hopeless, but Mr. Göschen seemed to invite an agitation for reduction. A reduction even to 4d could not but increase consumption.—Ed.]

THE ROYAL BOTANICAL GARDENS, PERADENIYA.

The name of the locality is derived from *Pera*, a guava, and *deniya*, an enclosed place; and there can be no doubt that this beautiful and fertile spot in a loop of the great river which has its main sources on the sides of the highest mountains in Ceylon,—Pidurutalagala, Kirigalpotta, and Totapala,—and in the tablelands of Nuwara Eliya and Maha Eliya, the latter 7,000 feet above sea-level, was once a royal demesne and a residence of the Kandyan monarchs. Indeed, according to the *Rajaratnakava*, as quoted by Tennent, Wikrama Bahu III held his Court here in the year 1371. Up to 1830-32, when General John Fraser, of Burgos and Kandyan war and rebellion fame, built the celebrated satinwood bridge, the Mahaweliganga (Ganges of Ptolemy) was here crossed by a ferry, which was the scene of a terrible disaster to the Portuguese arms, on one of the occasions of the advance of their forces to Kandy. A view, through the trees and up the river, of the satinwood bridge is one of the sights of the Gardens; while close by is a still greater triumph of engineering and structural skill in the shape of the iron lattice bridge by which the railway is carried into the heart of the ancient kingdom of Kandy, once as exclusive as Japan long was. It seems ridiculous now to read of the solemn ceremonies, amidst "dim, religious light," with which General MacDowall was received when he went to Kandy as the Ambassador of Britain. Amongst other sights of the Gardens are monuments to the memory of two former Superintendents, eminent as botanists and in scientific pursuits of an allied nature, such as geology in the case of Dr. Gardner and entomology in that of Dr. Thwaites. As eminently qualified as either and fully abreast of the wonderful advances which science has made in the present generation is the present Director, Dr. Henry Trimen; and happy the visitor to the Gardens who explores their treasures under the guidance of one so wealthy in useful and interesting information and so ready to impart it, in animated tone and popular form, as object after object passes in review, from the araucarias of the Himalayas and Australia, down to that woody creeper, with such a profusion of beautiful light lilac flowers, which has spread all over the country in the short period since Dr. Trimen introduced it from Madras,—the botanical name of which is *Ipomea carnea*.

* There is no such thing, we hope.—Ed.

In the buildings attached to the Director's residence, there is a library which is becoming very complete, a rich herbarium, a splendid collection of coloured drawings of Ceylon plants, and a useful assemblage of specimens of Ceylon timbers. There is also a laboratory for researches into the structure of plants, where one scientist has already done good work and to occupy which another is soon expected. We never coveted leisure—the power of disposing of our time according to inclination—so much as when we had to tear ourselves away from such objects, in the study of many of which we should have revelled. In going round the Gardens we were specially interested in a new and very conspicuous form of label, which is superseding all the former unsatisfactory expedients of zinc, wood, &c. The names are now marked in white paint over a black ground on the broad sloping faces of well burnt bricks, of good size and with long pointed ends running well down into the earth. These baked clay objects can, Dr. Trimen told us, be obtained in large numbers at an exceedingly moderate price, and their invention has solved a long-standing and great difficulty. When we next visit the Peradeniya Gardens we hope to be able to readily identify, by means of the new and almost indestructible labels, not only the forms of valuable and curious vegetation which have been introduced, but also our own interesting local floral and sylvan treasures. One thing we noticed which would seem to demand attention. The overground roots by which the group of ficus trees outside the gate are buttressed (why should some trees be thus supported and others not?) we found to be infested with white-ants, which had eaten the bark, if not some of the woody structure of the tops of those roots. A dose of the ubiquitous kerosene, properly diluted, might put an end to the rather destructive investigations of the termites? At "The Firs," Kandy, and in Peradeniya Gardens, we saw specimens of the beautiful weeping cypress, which ought to be grown in cemeteries. In the Colombo cemetery there is a beautiful young specimen of *Ficus benjamina* grown from a plant which we brought from Java in 1881 and which can be readily propagated. Its weeping habit renders it a perfect substitute for weeping willow. Amongst our notes we find reference to a tree, beautiful and useful for timber and firewood,—*Cupressus rhomboida*, seeds of which, we understood from Dr. Trimen, can be obtained at Hakgala. On the banks of the Mahaweliganga, which skirts the Gardens, a reed abounds which strangers might well be excused, if they mistook it for sugarcane. That cane grows well in Ceylon, but the juice of it in our climate is too watery for the manufacture of sugar. The plant which so closely resembles the sweet cane (a *saccharum* destitute of saccharine properties?) is that which gives its name to the railway station of Rambukkana, at the foot of the Dekanda Incline. We mentioned the concert of bird-notes in the Gardens, but forgot to notice the harsh interruption of the concert by a flight of screaming parrots, the bright glancing of whose plumage no more atoned for the absence of music in their souls than does the still grander adornment of the peacock alleviate the horror of its screams. Attempts have been made to initiate in these Gardens what Ceylon so sadly wants, a zoological collection. But on the pond, on the occasion of our recent visit, we saw only a solitary specimen of the sable swans, so many thousands of which crowd the Gippisland Lakes and other waters of Victoria. The fate of a couple of emus (the Australian representatives of the ostrich) which

we had previously seen here, bodes but ill for the longevity of the *rara avis in terris* who is at present

Like lady of the mere,

Lone sitting by the shores of old romance.

One of the queer Australian birds referred to was drowned while Dr. Trimen was recently absent in England, and the other met his fate on that sharp contrast to a path through "the bush,"—the railway. Amongst the unsolved mysteries must remain the question whether the catastrophes were due to accident, or to morbid feeling leading to suicide. In any case, the moral is that Ceylon, now becoming so rich in gardens devoted to botany, ought as soon as possible to relieve herself of the disgrace of having no zoological gardens, even at the capital. If Government gave a grant and made a beginning, we cannot doubt that gifts of animals, birds, reptiles, fishes, &c., would soon give us a very complete collection. Near the pond are specimens of aloes growing amongst rock work; various species of cacao, which is amongst our exports, are growing in the vicinity, while associated with the palms are plants which are often confounded with them,—cycads. Of another plant, which is popularly called "fan palm,"—the traveller's tree of Madagascar,—the foliage of which resembles that of the plantain, finer specimens are to be seen at Colombo than at Kandy or Peradeniya.—We have thus gone through a few of our notes, pencilled or mental, the result of a far too perfunctory visit to the beautiful scientific and landscape gardens at Peradeniya. But we find numerous notes on every page of Dr. Trimen's interesting Guide. To it and to the catalogue of over 2,500 species of plants grown in these Gardens, we must refer readers and visitors. We cannot, however, deny ourselves the pleasure of adding a few short extracts from the Guide:—

"The Royal Botanic Gardens at Peradeniya were established in 1821, six years after the final occupation of the Kandyan Kingdom by the English. The site is less than four miles from Kandy on the Colombo road, and occupies a loop of the river Mahaweli, which surrounds it on all sides except the south, where it is bounded by the high road. The area, nearly 160 acres in extent, is beautifully undulated; its average elevation above sea-level is about 1,540 feet. The climate is hot, moist, and very equable; the mean annual temperature is about 77° F., April and May being the hottest and December and January the coolest months.* Rain falls on about 200 days in the year, the annual rainfall being about 85 inches; it is pretty evenly spread through over the year, but is usually heaviest in October and November and in June, at the full establishment of the N. E. and S. W. monsoon, respectively. February and March are the driest months, but even then there are in most years showers at no distant intervals. * *

"Many rattans (**Calamus*)—climbing palms which make their way up to the summits of the tallest trees by their long tendrils closely set with grappling hooks. Their stems may attain a length of several hundred feet, and are the canes of commerce; nine or ten species are found in Ceylon.

"A plant of the vegetable ivory palm of Central America (*Phytelaphas macrocarpa*) will also be found here. There are many beautiful and interesting trees by the drive round the circle. The native "muruta" (**Lagerstrœmia Flos-Regina*) is surpassed by few when profusely covered with its large mauve-pink blossoms; another indigenous tree, the "del" (**Artocarpus nobilis*), has strikingly handsome foliage; the "goraka" (**Garcinia Cambogia*) yields bright orange or yellow fruits usually grooved like a tomato, and often of very good flavour, though inferior to those of the mangosteen. The young "bu" tree (**Ficus religiosa*) on the east side of the circle was planted by the Prince of Wales during his visit to the Gardens in

* In the early morning in December, the temperature has been rarely as low as 62° F.

December, 1875. This is the sacred tree of the Buddhists, always planted near their temples, and is the "peepul" of India.*

"Close to the river are trees of the candle-nut or Otaheite walnut (*Aleurites triloba*), a native of the Moluccas, &c., but much planted about Ceylon villages for the oil ("Kekuna-tel") expressed from the seeds. The nettlike plant, of which several beds will be noticed here and elsewhere, is the Rhea or Ramie of India and China (*Boehmeria nivea*), affording the fibre known as "China grass"; it has become a weed in the Gardens. Further on, in a small artificial swamp, are a number of sago palms (*Metroxylon Sagu*) from Borneo (sago is the food of the people in many of the Malayan islands.)

"The dark evergreen trees meeting overhead are old nutmegs (*Myristica fragrans*); the well known fruits are produced here through nearly all the year, and few objects are prettier than a ripe one when the yellow leathery rind has split naturally and half exposed the dark-brown nutmeg enveloped in the brilliant scarlet meshes of the "mace." The taller trees are cloves (*Eugenia caryophyllata*) and Jamaica allspice (*Pimenta officinalis*), and one tree of the less known spice called the Madagascar clove (*Ravensara aromatica*)."

DR. TRIMEN ON COCONUT LEAF DISEASE.

REASSURING REPORT.

I must apologise to you and your readers for trespassing on your space and on their time by a further communication. My excuse is the paramount importance of the coconut planting industry to the inhabitants of the maritime Provinces, and the cheering nature of a communication I have to make public. I forwarded to Dr. Trimen over a week ago a parcel of affected coconut leaves for his opinion, with a letter. He again gives it as his opinion that insects, and not a fungus, cause the discoloration of the coconut leaves, and that the causes are local. This is indeed reassuring, and must greatly cheer the hearts of those who had even the slightest misgiving about the "so-called" disease. As Dr. Trimen has kindly promised to see the disease *in situ*, it would be more courteous that I should defer any remarks on his letter until he has declared his final opinion after inspection on the spot. But I may be permitted to say (1) that the "alarming statement" to which he refers was, or was intended to be, only the expression of a fear, and (2) that though no complaints may have reached him from elsewhere, Veyangoda is not the only District affected, as I have seen the disease in every District I visited, and the Doctor himself might see it travelling by train, on the other side of the line, in many places.

The following is his letter, which though dated on the 11th reached my hands only this week, as I was absent from home:—

Peradeniya, 11th Nov. 1889.

Dear Sir,—I have to acknowledge receipt of your letter of 6th Nov. and the diseased coconut leaves.

Examination of the latter confirms me in the opinion that the affection is mainly due to mal-nutrition. I should suspect it to be the result of quite local conditions connected with the soil, especially as regards aeration and water-drainage. The spots are, in at all events the great majority of cases, the effects of the punctures of minute sucking insects, and not primarily due to any

parasitic fungus. Small fungi of two or three species undoubtedly occur on the leaves (it is difficult to find any leaves where they do not), but I am not inclined to think that they do any harm.

Really, I feel quite at a loss to understand on what foundation you make the alarming statement that "in this affection we are having the history of coffee-leaf disease repeated." Is the affection rapidly spreading over the country? I hear of no complaints from elsewhere than Veyangoda. Why, within a month of the first notice of *Hemileia* in Ceylon, there was probably not a coffee tree in the island unaffected.

My time is much occupied, but I will endeavour to meet your wishes and see the diseased trees *in situ*. I will give you timely notice of the day and hour.

Meanwhile, you should try to catch the little bug that sucks the young leaves by a careful watch, especially at night.

If there has been anything published in the "Examiner" on the disease, I should be obliged if you would let me see it.—Yours faithfully,

Cor., Local "Examiner." HENRY TRIMEN.

MELONS IN THE SOUTH OF FRANCE.—In the current number of the *Moniteur de l'Horticulture*, mention is made of the prodigious quantities of Melons consumed in the South. The writer says that at Nismes he was startled (*éffrayé*) at the enormous quantities of Melons (of the kind known as "Cavaillons"—i. e., a netted green flesh variety) displayed in the markets and in the streets, and supposed this to be the supply for a week at least. So far from that being the case, it represented only a day's supply, and the next morning a fresh lot of equal magnitude was to be seen. The inhabitants each consume one or two per diem on the average, the price their being merely 3d. or 4d., as contrasted with the cost in Paris, where it amounts to as many shillings.—*Gardeners' Chronicle*.

YAM-BEAN.—A packet of seeds of the Yam-bean (*Pachyrhizus tuberosus*) was received from the Director of the Botanical Gardens, Trinidad, from which a few healthy seedlings have been raised. In the Kew Bulletin of Miscellaneous Information, January 1889, it is stated that "seeds sent to Ceylon were grown by Dr. Trimen, and he discovered that not only were the tuberous-like roots edible, but that the pods were a very useful vegetable." He wrote, January 30th, 1888: "Last year you sent me some seeds of a tuberous vegetable, labelled *Dolichos tuberosus*. These grew well They are quite new to Ceylon, the vegetable being quite unknown here, and, I fancy, little grown in India. The young pods, served like French beans, are an admirable vegetable, tender and sweet; and the elongated arrow-root-like tubercles on the roots are also good when cooked. Altogether the plant is a decided acquisition to the vegetable garden. The flowers are pure white here."—*Proceedings of the A. H. Society of Madras*.

THE MUTTURAJAWELLA PADDY FIELDS.—These fields are situated in a large tract of land lying to the North of Hendala, extend as far as Pamunugama, and are between the old and the new canals to Negombo. During the time of the Sinhalese kings and later on in the Dutch times, these fields yielded an immense wealth to the people of the Island. Since then, no proper attention was paid to cultivate the fields successfully. The late Mr. Home made an attempt once but failed, and recently Mr. Jacob de Mel purchased a large block of the fields and with improved appliances is cultivating them, and it is believed that his efforts will not prove futile. In the construction of dams Mr. de Mel found at first many obstacles, as did the cultivators of the olden days; but he has so far overcome them. This enterprising Native gentleman has several Goiyas under him employed in the fields, and Government would do well to give all possible encouragement to him in his venture. The name of the fields suggests that they undoubtedly were of a very rich soil, and produced excellent crops of paddy. The grain produced was of such an excellent quality, that it was compared to royal pearls. This is the popular meaning of the name of the fields.—Cor., Local "Examiner."

* The sacred Bo tree at Anuradhapura, the ancient capital of Ceylon, is the oldest historical tree in the world, having been planted B. C. 288.

ANNUAL REPORTS ON THE STRAITS SETTLEMENTS FORESTS DEPARTMENTS: SINGAPORE, PENANG AND MALACCA FOR THE YEAR 1888.

ANNUAL REPORT ON THE FORESTS OF SINGAPORE, FOR THE YEAR 1888.

Area. 2. The total area of forests now under conservation has been increased from 13,043 to 13,133 acres by the addition of a piece of land at Bedoh taken over from the Land Office in September. This piece of land consists at present chiefly of *lalang** ground, but parts are damp and the soil rich, and it may prove of value when put under timber. The cost of demarcation was \$25.28.

Collecting plants and Seeds. 4. The Forest men have been instructed to collect in quantity any seeds or fruits found fallen from the trees in the forests and to send them in it to the Gardens, where they are planted and as soon as they have germinated and are fit to transplant are removed to the different places which required re-planting. Besides seeds and fruits, they have sent in young plants of various ornamental and useful species and, under my instructions, have recommenced sending in specimens for the herbarium.

Nurseries. 5. With the exception of the experimental nursery, little has been done in raising young stock. In the Jurong nursery there is a good series of young trees many of which are now ready to be planted out, and I hope shortly to be able to plant some of the waste lands on a more extensive scale. In the Bukit Timah nursery seeds of forest trees have been planted and have, for the most part, germinated well. It is intended to make nurseries round all the watchmen's quarters, whence young plants can be easily transferred to places requiring re-planting. In the Tanglin experimental nursery a large number of *seraya* and other useful timber trees have been raised from seed, and some of these have been planted out in the Military Reserve. Over 8,000 young plants of Para Rubber (*Hevea Brasiliensis*) were raised from seed sent from Ceylon. The young seedlings grew very rapidly, the largest of which have been put out in the Military Reserve. Others will be planted out in low-lying positions, such as the marshes of Jurong reserve, which are the most suitable localities for this species. The attempt to grow teak here on a large scale can only be described as a complete failure. The trees require the best soil that we possess, and there but few spots in the Colony where it will grow at all. Mahogany does a little better, and in some forests may be planted with advantage, but its cultivation here cannot be considered very successful. The bilion trees introduced from Borneo all perished, but I hope to be able soon to give this valuable timber tree another trial.

Extirpation of Lalang. 10. A very large proportion of the forest reserves is at present covered with *lalang* grass (*Imperata cylindrica* Cyr) which is not only useless, but very injurious, both by reason of its inflammability, and also on account of its preventing any cultivation of the land covered by it, except with a great deal of labour and expense. The subject, therefore, of the growth of *lalang* and its extermination is one of paramount importance. Wherever the land is burnt, or having been under cultivation is suffered to run to waste, it is soon covered with *lalang*, whatever may have been the previous vegetation. In comparatively rare cases, e.g., portion of the land burnt last year on the North-East side of Bukit Timah, the ground is covered with bracken (*Pteris aquilina*) or *Gleichenia linearis*. This I believe, to be due to the more sandy nature of the ground at this spot. It is noticeable that *lalang* will not grow on sandy or wet soil or under shade. In a few spots, the *lalang* grounds might be flooded for a time, and the plant thus destroyed, but owing to the configuration of the island this can rarely be done. The treatment of the soil by chemicals such as salt, sulphate of iron, &c., apart from the heavy expense

* The grass known in Ceylon as *iluk*.—ED.

connected with it, is liable to have a very injurious effect on the plants with which the ground is afterwards afforested even for many years. The introduction of some more actively growing plant to combat and destroy the *lalang* has been proposed, and the well-known *lantana* (*L. mista*) was suggested for this purpose. In every way this would be a most undesirable proceeding. To substitute for one noxious weed which, by its strength of constitution and vitality, is most injurious to cultivation, a plant yet stronger is merely to go from bad to worse, and as far as *lantana* is concerned the question has long been settled. In many places the *lantana* may be seen holding a precarious tenure in the midst of a *lalang* field and quite unable to compete with it.

The most hopeful plan for dealing with it lies in mechanical means. The plant must be hoed up and burnt and the ground re-planted. *Lalang* reproduces itself not only by its feathery seeds, but more constantly by its underground rhizomes. Hoeing it merely breaks these rhizomes into bits, and unless every bit is destroyed, the plant will reproduce itself from pieces of rhizomes left in the soil. Hence it is always said that *lalang* requires to be hoed up three times before it is destroyed.

To fire the plants as it grows, apart from the risk of injury to the timber-forests, only makes matters worse, for the fire merely burns the foliage and does not hurt the underground rhizomes, and the plants after burning usually bear fruit, which is carried by the wind all over the country again.

By constant clearing of the ground for a few years and at the same time planting with trees, the land may be eventually re-afforested with timber, but the expense of doing this on a large scale will be very great. When the trees are tall enough to throw a shade upon the ground, the *lalang* quickly disappears, nor can it penetrate even into forest glades if but a few trees bar its progress.

The question really resolves itself into one of expense. To re-afforest the whole of the *lalang* country in the forest reserves with timber would entail the employment of a large number of men for several years in clearing the *lalang* and re-planting the trees. The military reserve is an instance of this. It was commenced in 1885, and consists of 100 acres on which a band of 10 men has been employed each year for at least a portion of the year, and even previous to that plants likely to destroy the *lalang* had been planted there. Even at present it requires a constant clearing to prevent the recurrence of the *lalang*. The plan I would suggest for combatting the *lalang* is to plant gradually patches of ground at first with shade trees and bushes, perhaps of little or no value for other purposes, but which would form a compact but spreading head of foliage so as to shade the ground, then keeping down the weeds will be a comparatively easy matter. The present staff of watchmen will form little nurseries of trees in this manner round each of their quarters which they will be able to develop according as they have time from their other works. As the shade trees kill down the weeds, more valuable timber trees will be planted among them and in time a piece of valuable forest will be the result.

During my inspection of the forest reserves, I have noted the chief trees and shrubs which will grow through *lalang* both indigenous and introduced. Many plants will not grow in it at all, others grow through it eventually when assisted but do not kill it, while some with a little assistance will grow through and kill it.

Section (I).—Trees and shrubs that will grow through *lalang* without killing it:—

(*Adinandra dumosa*).

Teop-teop (*Mappa javanica*).

Singapore Rhododendron (*Melastoma malabathricum*).

Teak (*Tectona grandis*), in a very few rich soils.

Andong Cantley (*Dracena Cantleyi*).

Several species of wild Figs (*Ficus spp.*).

(*Embelia ribes*).

Gutta Jelutung (*Dyera costulata*).

Of section (I), teak, as stated elsewhere, is to all intents and purposes a failure here. *Adinandra* might be used as an accessory in keeping out *lalang*, but though exceedingly common, is difficult to propagate artificially. *Dyera* in certain spots is very common and is well deserving of encouragement on account of the rubber it produces. It gives little shade, being a tall straight tree, but not only can it grow through the grass, but in one spot I found plants which had at some time been under fire, throwing up side shoots, showing that the plant can stand burning. The remaining trees and bushes in this section call for no comment.

Section (II).—Trees and shrubs which grow through *lalang* and kill it:—

Arnotto (*Bixa orellana*).

Croton-oil (*Croton Tiglium*).

Flowering Cassia (*Cassia florida*).

Tembusu (*Fagraea peregrina*).

Tuba (*Derris elliptica*).

Mauritius Hemp (*Fourcroya gigantea*).

Of these, the Arnotto reproduces itself very rapidly and forms a low dense bush, under which nothing can grow. Croton seems likely to do well, but has not yet had a fair trial. *Cassia florida* is very successful, and eventually forms a fairly large tree. Tuba (*Derris scandens*) is stated to destroy *lalang* if planted among it, but I have had no opportunity of verifying it. *Fourcroya gigantea* will also grow among and destroy the *lalang* to a certain extent. *Fagraea peregrina*, as mentioned previously, is also a success. Besides which, I hope to try the purple *Jatropha* and some species of *Erythrina*.

Of course, it will be understood that in any case the process will be a slow one, and it will be a long time before the injury caused by the early destruction of the forests throughout the Colony is healed, but we may hope that as years go on it may be found possible to work more rapidly.

H. N. RIDLEY,

Director of Gardens and Forests, S.S.

ANNUAL REPORT ON THE FORESTS OF PENANG FOR THE YEAR 1888.

I.—Forest Reserves.

1. No addition has been made to the reserved forests during the year, but the areas demarcated in previous years have been surveyed, and prove to be of greater extent than the original estimate by 1,321 acres.

2. The total area under protection in the Island of Penang is 10,226 acres or a little less than 16 square miles; the total area of the Island being 107 square miles.

3. The greater portion of these forests are on the hill ranges at altitudes varying from 800 ft. to 2,750 ft. and although containing many excellent kinds of timber, would not at present pay for working; consequently the duties of the Department are for the present mainly protective.

4. During the early part of the year, these duties were not satisfactorily performed, but the appointment of Mr. I. Abrams to the post of Sergeant of Forest Guards in June resulted in a decided improvement.

5. Twenty-four persons were prosecuted for forest offences during the year, mainly for illicit cutting of timber, sixteen of whom were convicted, and eight discharged. The total amount of fines inflicted amounted to \$105, which, with the exception of \$5, were all paid.

6. The boundaries have been kept clear at a cost of \$128.35.

7. New quarters for the Sergeant of Forest Guards have been erected, at a cost of \$240, and alterations to the Assistant Superintendent's bungalow cost \$329.32.

8. A fire occurred in the village reserve at Kubang Ulu in January, which destroyed 10,000 young Mahogany trees planted out the previous season. The origin of this fire was not clearly ascertained, but from an examination of the spot immediately after, I am of opinion that it was owing to carelessness on the part of some person using the public foot-path at some distance from the reserve. It is worthy of note in connection with this that a clear path, fourteen feet

broad, was useless in arresting the progress of fire travelling through *lalang* grass, and it is doubtful whether double that width would have been of any use.

9. The vacancies caused by this fire have been filled up to the extent of the remaining stock of young Mahogany plants in the Nursery, but judging from the progress made, both here and in Penang, this tree is not likely to be of great value in this Settlement.

10. In accordance with instructions received from His Excellency the Governor, the Assistant Superintendent visited the Dindings in January and July, with a view to obtaining information as to the condition of agriculture, and to assist in setting approximately the forest areas to be reserved. Copies of the reports submitted as the result of these visits are annexed. (Appendices B C D.)

11. As this district supplies a large proportion of the timber used in Penang, and contains the only large workable forests of the Colony at this end of the Settlement, no time should be lost in putting them under proper management.

12. The total expenditure in connection with the maintenance of Forest Reserves is \$1,690.36, as shown in statement of expenditure annexed. (Appendix A.)

II.—Kubang Ulu Nursery.

13. Little new work has been undertaken in this nursery, as it was hoped that a more suitable site would have been acquired and laid out during the year, in accordance with the suggestion put forward in last annual report, but unfortunately the year closed without this being carried into effect.

14. I would again point out the necessity of acquiring suitable land on which to test the value of new and little cultivated vegetable products.

15. Through the kindness of Thompson Low, Esquire, of Caledonia Estates, I am enabled to give the result of an analysis of twelve varieties of the sugar-canes referred to in last year's report as having been introduced from the Mauritius. (Appendix E.)

16. Some of these promise to be in advance of any kind at present cultivated in this Settlement, but their real value cannot be estimated until they have been grown on better land than is at my command.

17. A large number of Liberian coffee plants were raised from seeds ripened in Perak, some of which have been planted in the Dindings. Plants were offered free of cost to the Malays and Achinese in the neighbourhood, but they did not avail themselves to the extent that is to be desired.

18. A few pepper plants put out in 1885 were bearing a good crop of fruit at the end of the year, but there is no necessity for experimenting with this, as its cultivation is thoroughly established at Ara Kuda, from whence thousands of cuttings and plants are now sold to the Native States.

19. One thousand eight hundred and twenty (1,820) trees for planting the road-sides in Province Wellesley have been supplied from this nursery during the year.

III.—Hill Nursery and Bungalow Garden.

20. The special grant of \$1,000 for the improvement of the Bungalow Garden admitted of much necessary work being done. The working of the nursery and garden together, instead of from separate votes as in previous years, is also an advantage.

21. The top of Gun Hill has been cleared, levelled, and laid out as tastefully as the site would admit. A rustic summer-house, and a temporary plant shed, have been erected, and the latter filled with plants requiring a lower temperature than is obtainable in other gardens. Most of the *Cattleyas*, *Odontoglossums*, *Rhododendrons* &c., have been removed to this shed, as being not only cooler, but easier of access to persons occupying the bungalows.

22. The "Round," near the entrance to the Convalescent Bungalow, has been cut down six feet, and the area of the site enlarged with the soil removed, *Grevillia robusta* and *Juniperus virginiana* have been planted around the outer edge, and this site is now available for tennis, &c.

23. The approach to the Convalescent Bungalow, which was in an untidy condition has been cleared, dug over, sloped and turfed.

24. The long continuous flower beds on the terraces have been broken up into irregular groups, and entirely replanted, the intervening spaces being turfed.

25. The rose beds have been deeply trenched, and, as far as possible, re-planted with grafted or budded plants propagated on the spot, and these are doing much better than plants on their own roots. Many new varieties have been introduced from Calcutta, and it is hoped that by the end of another year the garden will be well stocked with young thriving plants.

26. The area available for vegetable cultivation has been greatly extended during the year, by cutting away the jungle and forming additional terraces. The cultivation of vegetables will, in future, be principally confined to this garden as it is in close proximity to the stables and piggery, the latter having been put up for the express purpose of obtaining manure.

27. The five pigs purchased in December, 1887, have increased during the year to twenty-one; the total cost of food being \$76.01.

28. The general up-keep of roads, paths, &c., always an important item where the rainfall is heavy as in Penang, has been well attended to by Mr. Chandler, as well as the supervision of coolies employed on the various improvements already detailed. It is to be regretted that this Officer is leaving, as it takes at least a year for a man with no previous experience of working coolies or gardening, to acquire the knowledge necessary for carrying on the work economically and expeditiously.

29. The capabilities of this garden have never been fully developed, no one with a practical knowledge of the cultivation of plants having been stationed on the spot, and the Officers appointed to the post of Signal Sergeant leave, or are removed, by the time they begin to take an interest in this subject.

30. In the Experimental Nursery there has been a greater amount of fever than usual among the men employed, and very frequent changes.

31. Since the promotion of Mr. P. Nieukey to the post of Overseer, Waterfall Garden, in June last, no competent man has been in charge of this nursery. Applications were made to the Singapore and Calcutta Botanic Gardens, but in neither case could a man be spared. An advertisement was then inserted in the local newspaper, but the applicants were none of them of the class to be desired. Eventually a Ceylon man,* whose testimonials as to general character were satisfactory, but with no previous knowledge of garden work, was taken on probation, but during the absence on leave of the Assistant Superintendent in November he left under the plea of ill-health.

32. In spite of this difficulty, the general up-keep has been fairly maintained, and the young stock made satisfactory progress.

33. The tree tomatoes continue to bear, and one of the apple trees from Australia produced eight fruits of large size and fair flavour. The oranges and citrons should commence bearing next year.

43. The olives continue to make progress, one tree having attained a height of twelve feet, with a circumference of six inches at the base, but there is no sign of its producing fruit.

V.—General.

57. Four hundred species of Penang plants have been added to the herbarium, and duplicates of each forwarded to the Royal Gardens, Kew, for determination. Two hundred and seventy surplus specimens have been presented to other botanical establishments, and eighty received in exchange.

58. One thousand one hundred and twenty-two plants, and sixty-three packets of seeds, exclusive of those obtained by purchase, were received during the year; and two thousand five hundred and forty-one plants, and sixty-one packets of seeds distributed, exclusive of those supplied for road-sides. A list of the principal donors and recipients is given in Appendix G.

C. CURTIS,

Assistant Superintendent of Forests, Penang.

* Who can this be?—Ed.

APPENDIX B.

REPORT ON THE FORESTS OF THE DINDINGS.

As pointed out in my report on the agricultural condition of this District, the timber and other forest produce constitutes a most valuable crop, in many places of greater value, all things considered, than anything that could be put on the land were the existing forests destroyed.

2. The District has not been surveyed, but the approximate area is two hundred square miles, of which, so far as I can judge from a hurried visit, at least two-thirds are more or less covered with forests containing a large proportion of valuable timber trees, such as, *Chengal*, *Damar laut*, *Tampenis*, *Merebau*, *Meranti*, and others of more or less value; which, properly managed, will prove a permanent source of revenue.

3. The population is scanty, and consequently there are but few of the difficulties to be met with that have been encountered in demarcating and settling the reserved areas in other parts of the Straits Settlements.

4. The facilities for removing and marketing the produce in Penang are greater than in any other Crown forests at this end of the Settlement.

5. Local steamers call regularly at Pangkor for firewood, and as the trade between Penang and Lower Pérak increases, the demand for firewood is certain to increase also, thus affording a market for produce that is often wasted or of little value.

6. Other sources of revenue are, damar, wood-oil, rotans, getah, bertam, &c., all of which will have to be taken into consideration in the future administration of these forests.

7. The present system of allowing Chinese to cut where and how they choose, on payment of royalty to the Government varying from three to nine cents per cubic foot for logs up to twenty feet in length, and a proportionally higher sum for greater lengths, will, in a few years destroy all the more valuable timbers. In some places this is already the case, as I am informed by the District Officer, who remarks, and my own observations agree, that one of the most valuable timbers—*chengal*—will soon be exhausted unless protection and a different system of working be applied.

8. The same thing has happened in Penang with the best form of damar laut, (*Shorea* sp.) which is specifically distinct from, and vastly superior to, the timber now generally known under that name.

Old Malays inform me that the best form of damar laut, known as *No. satu* was plentiful thirty or forty years ago, but I know from experience that at the present time it is difficult to find a single tree.

9. The revenue derived from forest produce in the Dindings during the past three years amounts to \$20,611.01, but I have no information what proportion of that sum is derived from minor products. I think, however, it may be safely assumed that for this sum half a million cubic feet of timber have been removed, and a large quantity wasted, as there is under the present system no incentive to economy in working.

10. The suggestions I have to offer are that a large proportion of this District,—(a) be declared Forest Reserve, and worked on a system that will ensure natural reproduction from seed, and also ensure that the quantity of timber removed does not exceed the annual yield of the forest; (b) to do this the reserved area must first be marked out in blocks, and compartments, for convenience in working, the boundaries surveyed, and suitable maps prepared; (c) by careful examination the contents of each compartment should be ascertained, the kinds and proportion of timber trees and other revenue-yielding produce noted, and the approximate normal yearly increase ascertained; (d) trees to be removed during the year from the compartment or compartments to be operated on should be marked by a competent person, and then sold by auction standing, removed by Government agency, or under a modification of the present system, as experience may prove best; (e) restriction should be placed on the manufacture of "Sagors" by which process the greater portion of a whole tree (generally *Chengal*) of the first class is entirely wasted, to form the bottom portion of a native

boat; (f) the cutting of certain valuable trees that are becoming scarce, to be specified after careful examination, to be entirely prohibited for a number of years; (g) the protection of getah trees, rotans, and other minor products, should receive attention, and artificial reproduction resorted to, if necessary, though immediate protective measures will probably render this unnecessary except in the case of very scarce and valuable trees, &c.; (h) separate reserves for firewood should be established on the banks of the rivers, where the vegetation is principally bakau.

11. The need of a small protective staff in order to check the illicit removal of timber, &c., is already felt by the District Officer, and the system I have ventured to suggest cannot be carried out without the assistance of intelligent men.

12. The object should not be to obtain the greatest possible immediate revenue, but to bring the forests into the condition in which they will produce the best kinds of timbers, and prove a permanent source of wealth.

C. CURTIS,

Assistant Superintendent of Forests, Penang.

Appendix D.

Penang, 31st January, 1889.

Sir,—I have the honour to report, for the information of His Excellency the Governor, that, in accordance with instructions, I proceeded to the Dindings on January 19th, taking with me a case of economic plants in pots, the weather being too dry at the time for lifting plants from the open ground.

2. During six days I travelled over as much of the District as was possible without the aid of a steam-launch, which was unfortunately in dock, and examined the state of agriculture and nature of the soil.

3. With the exception of Lumut Estate, on which tapioca and sugar are grown, the principal cultivated products appear to be coco-nuts and patchouly, both of which give a good return. The tapioca crop is looking well, and the machinery for manufacturing flour will be erected shortly.

4. Pepper is being tried on a small scale in three or four different parts of the District, and grows well, especially near the District Officer's house at Pangkor, but the proper method of cultivation is not understood by the owners. The plants have been allowed to grow up to the tops of the supports, instead of being layered as is done by the Achinese planters in Province Wellesley. I explained to them practically, by treating plants in their presence, that when a pepper plant begins to branch it should be taken down from its support, the lower leaves removed, and the stem up to the junction of the branches layered down in a previously prepared hole as near the support as is consistent with the safety of its roots, and the soil then replaced. Treated in this manner, roots are emitted along the whole length of the stem that has been buried, the plant is better able to withstand drought, and fruit is produced from near the ground up to any height that may be desired.*

5. At Rája Itam, which was reached by walking for five or six miles along the boundary line that divides the Dindings from Pérak, I saw near a native house a plant of China grass (*Rhea* or *Ramie*) which has attracted considerable attention of late on account of its valuable fibre. The owner of the garden stated that he was in the habit of cutting it down for the manufacture of fishing lines about once a month. At the time I saw it the shoots were four or five feet high, and as clean as could be desired. The soil at this place is a peculiar clayey loam of a light colour.

6. There are a variety of soils in the District, some of which would produce cloves, nutmegs, pepper, Liberian coffee, chocolate, indigo, coco-nuts, paddy, &c.

7. In order to encourage the cultivation of economic products other than those mentioned in para. 8, which are already established, especially pepper, coffee, cloves and nutmegs, I would suggest the formation of a small nursery in Pangkor, of about an acre in extent, where plants could be raised or planted temporarily

on their arrival from Penang or Singapore, previous to distribution to intelligent natives willing to give them a fair trial.

8. After careful examination, in company with the District Officer, we came to the conclusion that the most suitable place for this purpose would be a piece of land near the Recreation Ground, which combines the advantages of fairly good land with an abundant water supply, and is sufficiently near the District Officer's quarters to allow of his personal supervision.

9. This land would have to be cleared and fenced to keep out animals, and a small house put up to accommodate two gardeners, who would be sufficient to carry on the work when it is fairly started.

10. The cost of clearing, fencing and stocking this nursery, including young plants of cloves, nutmegs and pepper to be purchased this year, need not exceed \$500, and the other up-keep would be the salaries of two Javanese at about \$18 per mensem.

I discussed the matter thoroughly with Mr. Merewether, who takes an intense interest in the matter, and one of the first things done would be to raise a quantity of dadap and pepper plants for distribution, a supply of seeds of the former being available on the spot.

11. There is regular communication between Penang and Pangkor, and seeds are easily transmitted, and an Officer of this Department could occasionally run down for a day or two to give practical instruction.

At present there is no accommodation for visitors to the District, which doubtless prevents many persons, who would otherwise do so, from spending a day or two on the Island, and judging for themselves of the capability of the soil, &c. I understand, however from the District Officer, that it is intended to erect a Rest-house on the beach which will be a great convenience.

12. It should be borne in mind that, while there is great need for developing the agricultural capabilities of the Dindings, the Government possess in the existing forests a most valuable crop, which in some parts of the District, considering the nature of the soil, quality of the timber and the facility with which it can be brought to market, is, if carefully conserved and economically worked, probably of greater value than anything that can be planted, besides the advantages of having a fair proportion of forest land as regards its bearing on climatic changes.

13. These areas should be settled in good time, and their extent and position shown in the map when the contemplated survey of the District is undertaken.

C. CURTIS,

Assistant Superintendent of Forests, Penang.

ANNUAL REPORT ON THE FORESTS OF MALACCA, FOR THE YEAR 1888.

1. The work of the early part of the year was carried out by Mr. Flanagan, but on my return from duty in Singapore, in the middle of April, Mr. Flanagan was transferred to the same Settlement.

Forest Reserves.

2. The work of the year has consisted chiefly of maintenance. In some districts, small nurseries are being established for raising seedlings of the best kinds of forest trees for planting up waste lands within the reserves.

3. Much difficulty has occurred in keeping the forest watchmen from frequently absenting themselves from their station; this is owing to their quarters not being large enough for them and their families. Quarters similar to the Police barracks are what are required.

4. During the year, one Corporal of forest watchmen has died, and one has resigned.

5. It is satisfactory to note that no fires have occurred within the reserves during the year.

6. In Appendix A is a list of prosecutions for illicit wood-cutting detected by the forest watchmen.

7. The following general notes are made with reference to the forest reserves.

Bukit Bruang Reserve.

8. Six miles from Malacca, situated between the districts of Batu Berendan and Durian Tuanggal, has

eight and-a-half miles of boundaries, and an area of 1,734 acres.

9. The hill-land rises to an elevation of 514 feet, and occupies a large area of the reserve; it is well wooded with young timber, the most abundant and notable being *Tampines* (*Sletia sideroxyylon*).

10. Conservation appears to be all that is required in this districts.

Sungei Udang Reserve.

11. Thirteen miles from Malacca, situated between the districts of Sungei Udang, Sungei Baru and Pangkalan Balak, has fifteen miles of boundaries, and an area of 4,800 acres.

12. The reserve is well wooded, and includes a fair percentage of first class timber on certain areas.

The most notable are:—

Kayu Minyak (<i>Dipterocarpus levis</i>),	abundant.
Kempas (<i>Kumpassia malaccensis</i>),	... do.
Seraya (<i>Hopea cernua</i>),	... do.
Meranti (<i>Hopea meranti</i>),	... do.
Malaka (<i>Phyllanthus emblica</i>),	... do.
Kelat (<i>Eugenia zeylanica</i>),	... do.
Kranji (<i>Dialium indicum</i>),	... fairly abundant.
Arang (<i>Diospyros sp.</i>),	... do.

13. All the old Jakun clearings within the reserve are fast becoming re-wooded by natural reproduction.

14. An abandoned estate adjoining the Pangkalan Balak Road, and near the sea, requires to be assisted by some planting, and this will form part of the operations for 1889.

15. Some young plants of Mahogany raised from seeds received from Kew and planted in this district during the year, have nearly all succumbed to the ravages of ants.

Merléman Reserve.

16. Twenty miles from Malacca, situated between the districts of Merléman and Chinchin. Boundaries extend eight miles, area computed at 4,000 acres.

17. The northern boundary has been re-opened during the year, but, owing to the deep swamp, it is impossible to keep the boundaries in the direction of the Kesang River in order.

Much good will be effected in this reserve when the Kesang River has been cleared.

18. The western portion of the reserve is well wooded, and some first class timber skirts the Ohinchin Road, which passes through the centre of the reserve.

The most remarkable are:—

Tembúsu (<i>Fagraea peregrina</i>),	fairly abundant.
Petaling (<i>Strombosia javanica</i>),	do.
Meranti (<i>Hopea meranti</i>),	abundant.
Kayu Minyak (<i>Dipterocarpus levis</i>),	do.
Gambar daun,	... fairly abundant.
Rambei daun,	... do.

Ayer Panas Reserve.

19. Fifteen miles from Malacca and situated between the districts of Durian Tungal and Kesang. Area 4,000 acres. The reserve is chiefly demarcated by the public roads.

20. Demarcation of the western boundary of the new reserve has been completed during the year.

21. The reserve is wooded chiefly with young forest, except the roadsides, where some first class timber exists.

The most notable are:—

Resak (<i>Fatica rassak</i>),	... fairly abundant.
Sepete (<i>Parkia Roxburghii</i>),	do.
Jelutung (<i>Dyera costulata</i>),	do.
Gambar daun,	... do.
Meranti (<i>Hopea meranti</i>),	... abundant.
Kayu Minyak (<i>Dipterocarpus levis</i>),	do.
Kranji (<i>Dialium indicum</i>),	... fairly abundant.

Bukit Panthur Reserve.

22. Sixteen miles from Malacca, situated between the districts of Machap, Durian Tungal and Alor Gajah, has eleven miles of boundaries, and an area of 3,640 acres.

23. The hill-chain reaches an elevation of 889 feet, and, besides protecting the sources of springs in the backbone of the Settlement, it is well wooded with young forest, and is in the centre of a largely cleared district.

24. An abandoned estate now included within the reserve will require some time before re-wooding itself by natural reproduction, and some artificial assistance may be necessary on so large an area.

25. The most notable trees are:—

Merebau (<i>Afzetta palembanica</i>),	rare.
Kelat (<i>Eugenia zeylanica</i>),	fairly abundant.
Petaling (<i>Strombosia javanica</i>),	rare.
Kempas (<i>Kumpussia malaccensis</i>),	fairly abundant.
Meranti (<i>Hopea meranti</i>),	do.

Brisu Reserve.

26. Twenty-five miles from Malacca, and situated between the districts of Sungei Baru, Lubok China, and Brisu. Has nine miles of boundaries, and an area of 2,247 acres.

27. The reserve is principally wooded with young forest.

The most important trees are:—

Seraya (<i>Hopea cernua</i>),	... fairly abundant.
Meraui (<i>Hopea meranti</i>),	... do.
Kelat (<i>Eugenia zeylanica</i>),	... do.
Kayu Minyak (<i>Dipterocarpus levis</i>),	do.

28. The demarcation of inhabited lands, and an extension towards the frontier, will form part of the operations for the year 1889.

Jús District.

29. Nothing could be done in the large district of Jus, but demarcation has now commenced.

General Remarks.

30. It has been thought that the time has arrived when some revenue might be raised from the reserves, by supplying timber and general forest produce to the different villages.

31. With this object in view, the principal operations for the year will consist in preparing reliable maps showing all the topographical features, and the reserves marked into blocks.

32. The reserves will be marked into blocks by means of inspection paths, and each block will be dealt with separately. The timber will be classified, waste lands to be planted will be noted, brushwood requiring artificial assistance, either by planting, thinning or sowing seeds, will be marked, and all possible information collected and recorded.

It will then be left to decide what timber can be spared from the different blocks, and, with the necessary information to work on, the fellings can be properly controlled.

Bukit Sabukar Experimental Garden.

33. The most important work of the year has consisted of maintenance, propagating and planting, and clearing and preparing ground for the reception of plants for experiment and nursery stock.

34. Seeds of forest trees, rotans, &c. have been sown from time to time for general planting.

35. Perhaps the most important work in this direction has been the preparation of seedling fruit trees for distribution. From applications received and notified, it is evident there is a large demand for the principal kinds of fruit, both in the Settlement and Native States, and several thousands will be prepared during the year 1889.

36. The nucleus of a collection of general economic plants has been introduced during the year.

37. The following notes are made on experiments now being carried on.

38. Mauritius hemp (*Fourcroya gigantea*) grows slowly but well, some fibre has been prepared from a few old plants, and has the appearance of good fibre.

39. If kept free from weeds, nothing further appears to be required to ensure success.

40. Virginian tobacco (*Nicotiana tabacum*, var.).—From seeds received from Kew, a fine lot of plants were raised; but from seeds saved locally, the plants deteriorated so much that the cultivation has been discontinued.

41. Deli tobacco (*Nicotiana tabacum*, var.) has been tried, but this has also proved unsuccessful.

42. Castor oil (*Ricinus communis*).—Seeds were obtained from the Botanic Gardens at Calcutta. The plants have grown vigorously and are now commencing to fruit.

43 Croton oil (*Oroton tiglium*) grows freely and fruits abundantly.

44 Annato (*Bixa orellana*) grows vigorously, and is deserving of a trial on a large scale.

45 Black pepper (*Piper nigrum*) grows well in the Settlement, and might be more extensively cultivated to advantage.

46 Cubebs (*Piper cubeba*) promise well, and are being propagated as largely as possible.

47 Maltese oranges and lemons.—The lemons have grown well and are now flowering.

48. Mahogany (*Swietenia mahogani*).—Seeds were received from Kew in 1886. The plants have grown well, and many are now ten feet high. Unfortunately, few are free from the ravages of ants.

49. Two species of *Eucalypti* have grown with remarkable vigour, and it would be interesting to try these valuable trees on a larger scale.

50. From a sample of Liberian coffee observed to be growing well in the Settlement, and sent to the Kew authorities for report, the London Brokers to whom the sample was submitted, declared it to be the finest sample of Liberian coffee ever seen in the London market.

Roads and Drains.

51. The main drive through the Garden (from the Garden boundary to the Batu Berendan Road) has been widened and maintained, and now admits of a drive through the extent of the Garden.

52. A road, 500 yards in length, has been opened to the Assistant Superintendent's quarters.

Formation.

53. In July, a supplementary vote of \$1,000 and in October a further vote of \$200 was sanctioned, for digging a lake, and levelling the adjoining grounds.

54. The excavations were continued to the end of the year, and 5,000 cubical yards of earth were removed.

55. A dam remains to be constructed, and a vote will be required for the work, which should be completed as early as possible, as an abundant water supply close at hand is absolutely necessary.

56. It may be mentioned that the rainfall for the first four months of the year, taking the average for that time from 1883-86, amounts only to 3.60 inches monthly. Much labour is now lost through fetching water from long distances.

Assistant Superintendent's Quarters.

57. Quarters for the Assistant Superintendent were completed at the end of August, and occupied on the first of September.

58. A statement of Expenditure is appended in Appendix B, and of Revenue collected in Appendix C.

R. DERRY,

Assistant Superintendent of Forests.

Malacca 11th, February, 1889.

CULTIVATION IN THE CAYMAN ISLANDS: COCONUT PALM DISEASE.

(From Report by the Director of the Public Gardens and Plantations on the Cayman Islands.)

Botanical Department, Gordon Town P.O.,
Jamaica, 22nd December, 1888.

The Cayman Islands, consisting of Grand Cayman, Little Cayman, and Cayman Brac are situated about 180 miles to the north-west of Jamaica, and perhaps the same distance south of the centre of Cuba, that is to say, between the meridians of 79° 44' and 81° 26' W. and the parallels of 19° 44' and 19° 46' N.

Grand Cayman is the largest of the group. Its greatest length, running east and west, is stated to be 17 miles, but the road which passes along the south coast must be twice as long. It is 4 or 5 miles broad at the eastern end, and 7 or 8 at the west end. A large bay, 6 miles across, called the "Sound," cuts into the land on the north side, so that the western portion of the island is a narrow slip from half to one mile broad. The island is low, and surrounded by coral

reefs. The "Handbook of Jamaica" states that "the coast is in some parts bold and rock-bound, but with no elevation exceeding 150 feet;" but certainly in the western part of the island, the elevation is nothing like so much.

The beach in all the islands is composed of the debris of coral, the pieces ranging in size from large lumps to fine sand. Within the beach the coral is consolidated into a limestone rock, but the surface is very rough and uneven, due probably to the carbonic acid in rain-water acting with different degrees of intensity on the varying character of the rocks. The residue from this chemical action is the red clay which forms the soil. In Cayman Brac, along the west coast, there are cliffs at a short distance from the shore 40 or 50 feet high. The character of the islands from a geological point of view appears to be similar to that of the formation known as the "white limestone" in Jamaica.

With regard to cultivated plants, it may be gathered from the nature of the soil, and the wild plants that there would be a general resemblance to those of Jamaica. In Grand Cayman mangoes are not so plentifully distributed as here; they grow into fair-sized trees; fruit was not ripe, but was said to be inferior to some of the Jamaica mangoes. Oranges, both sweet and bitter, and a few lemons are produced, and great quantities of limes are exported pickled. Yams, cocoons, sweet potatoes, cassava, pine-apples, melons, sugar-canes, bananas, guinea-grass, all flourish. I took a few good pinesuckers with me and gave them to the Custos for trial. The sugar-cane looked poor but I was told that its indifferent appearance was due to long-continued drought, and that canes grow sometimes from 12 to 15 feet in height. There are a great number of papaw trees, some with thick trunk and several branches; the fruit is usually large and fine. There is a good deal of log-wood, fustic, mahogany, and hard-wood timbers. The log-wood trees appear to be mostly young, all that was fit to cut having been exported. The mahogany and hardwoods are used in the construction of well built schooners up to 50 tons, the softer timbers for plank-ing being important from the United States. The good timber has been almost all cut down in the woods to the west and south; but I was told that there are great numbers growing still on the north side, where also the soil is deeper and richer, and more cultivation carried on than elsewhere. I was sorry not to have been able to go there, but as it was doubtful whether I could go and return in one day, I had to abandon a projected visit. It would be interesting to know what these timber trees are. The guava and the coco plum grow wild. I saw two Coffee trees growing not far from the sea, and even in May after 6 months' drought, there was a fair quantity of berries on them. This is probably the first attempt to grow Coffee in these Islands, and the result appears to justify planting, where the soil is sufficiently deep.

In Little Cayman there is Mahogany but no Cedar (*Cedrela odorata*); and in Cayman Brac there is plenty of Cedar, but scarcely any Mahogany. In Little Cayman I was told that there is no logwood nor fustic, and that there was no logwood in Cayman Brac, but in the latter island I found fustic in the woods.

Coco-nut Palms grow on Grand Cayman, and Cayman Brac. Disease has for several years blighted the Palms in Grand Cayman, but no disease has appeared in the other island and I was informed that some 600,000 to 800,000 nuts are annually exported.

11. No accurate information could be obtained from the people as to the first appearance of the disease, some said it was 15 years ago, others again thought that it might have been 40 years. In a dispatch from the Marquis of Sligo in 1834, he mentions that all the Coco-nuts of the leeward side had been destroyed, but that the infection had not reached the windward side. It is probably that this was the same deadly disease. I saw a great number of these palms of different ages in various stages of the disease, and at several localities. From George Town I went northwards about 7 miles to north-west point, and east-

wards about 15 miles, some distance beyond Bodden Town. Seed is constantly brought from the mainland and the inhabitants have been most persevering in their efforts to re-establish their coco-nut walks, but it is of no avail. A grove may do well for a time, and produce a crop of fruit, but suddenly it is attacked, the disease often first seizing the tallest and finest palm. Or, again, the palms may all die off when they are from 6 to 10 feet high, without producing any fruit. The disease is quite independent of the direction of the wind, travelling as often against it as with it. The outer leaves first show signs of the disease, gradually turning yellow, but I had several palms cut down, and invariably found that it was the bud leaves which were actually affected at the apex, and as the disease gained ground the outer leaves lost their green colour. Sometimes on cutting the stem right through just above the ground, it appeared perfectly untailed and smelt and tasted sweet. At other times when the disease had made more progress, though the stem section looked white, it smelt and tasted sour, and this occurred even when only the upper portion of the "cabbage" was discoloured. The discoloured portions were of a purplish black colour, eventually becoming quite black. There was no sign of either the scale insect or the beetle which attack the Coco-nut Palm in Jamaica. In the early stages of the disease there is no appearance of an insect, but after decay has set in, various insects may be found such as ants, a small beetle called the "coco-nut fly" and a white larva which may be that of the coco-nut fly. The only remedy that I can suggest is to take up each diseased coco nut palm by the roots and burn the whole of it, root, stem and leaves on the spot where it was growing. To be effectual, it should be made compulsory by a local regulation, and some one should be appointed to think that this plan is the only chance of getting rid of it. And, I repeat, every single diseased palm without any exception, where it is found, must be exterminated. I suspect that the disease is due to the presence of a bacterium, and it is possible that it may gain access to the tissues through the stomata of the tender bud-leaves. Lime and phosphate probably encourage the disease, and it would be well to try the application of cattle-manure by digging it in round the roots, or, if this is not available, decaying weeds and other vegetable matter.

Increased attention might be given to various products, and a fair trial made of the cultivation of coffee. Common or Arabian Coffee appeared to do well, but it should be planted under shade trees. Liberian Coffee would no doubt succeed much better than Arabiau and sell well in American markets. In Johore Liberian Coffee from the 3rd to the 4th year yields about 3 cwt. per acre, and after that from 5 to 6 cwt. If any persons wish to start this cultivation, seed could be supplied from the Jamaica Gardens. Information as to planting, &c., is given in the Jamaica Bulletins Nos. 4, 5 and 6, and though these articles refer to Arabian Coffee grown on the mountains, the general method of cultivation can be easily ascertained and applied to Liberian Coffee grown at sea-level. Hand-pulping Machines are made by ordinary carpenters in Jamaica and could therefore be made also in the Cayman Islands from a pattern. It would probably be advisable to export common coffee in parchment, but Liberian Coffee should be thoroughly cleaned. (See Kew Bulletin, No. 23, Nov. 1888.)

In cultivating products beyond the actual needs of the inhabitants, it will be well to give the first place to such as not only suit both soil and climate, but also are readily exported to foreign markets. For instance, probably no island in the West Indies is more suitable for the cultivation of pine-apples, if well drained areas are chosen for planting, but the fruit does not last long, and the means of transport are both limited and uncertain. It is not advisable therefore to extend the cultivation of anything quickly perishable, unless it can be preserved by some means. Prepared articles like arrowroot, tapioca, guava jelly, can easily be stored until favourable opportunities occur for exporting them. Again, there is a good market for yams at Oolon and Port Limon; the value

of this export in Jamaica has risen from £43 4s. 8d. in 1881 to £15,978 18s. 8d. in 1887. Bananas, O aones, and Mangoes would pay well, if there were schooners sailing regularly to New Orleans.

W. FAWCETT,

Director of Public Gardens and Plantations, Jamaica.

THE SPROUTING OF SEEDS.

We take the following condensed summaries "On the influence of Certain Conditions upon the Sprouting of Seeds," from the July *Bulletin* of the Agricultural Experiment Station, Cornell University, Ithaca, N. Y., wherein, with a few to determine, will be found full details of the experiments made on the circumstances and conditions affecting germination, and a discussion on the results obtained:—

Influences of Constant and Variable Temperatures.—Different results are obtained from the same sample of seeds under different variations of temperature, of which the daily mean is essentially the same.—Sprouting takes place more quickly under essentially constant temperature of about 74° than under a temperature ordinarily variable, which gives about the same mean.—Rapidity of sprouting is particularly marked in Beans and Peas.—As the mean temperature becomes lower, rapidity of sprouting becomes slower.—Greater rapidity of sprouting does not appear to be correlated with greater per cent. of total sprouting.—Constant temperature, of the degree here mentioned, does not appear to give greater percentages of sprouting; at least, the variation in this respect between the constant and variable temperatures is no greater than that which is usually obtained from tests conducted under identical conditions. In the seven tests with Beans, however, there is an average gain of 5 per cent, in favour of those under constant temperature.

Influences of Different Quantities of Water upon Sprouting.—The quantity of water applied to seeds under test may make a remarkable difference in the results.—Sprouting is decidedly more rapid in tests which receive less than the usual amounts of water given in greenhouses. This is markedly the case in all the tests, with the exception of three indifferent and comparatively unimportant instances.—Per cent. of sprouting is much greater, as a rule, in the drier tests.—The addition of water above the amount to keep the earth simply moist, is injurious.—The wide differences between the results of the wet and moist tests are not necessarily due to the rotting of the seeds in the wet tests. This is shown in the tests with Cucumber seeds, in which the drier tests gave similar or even smaller totals than the wet tests.

Influences of the Soaking of Seeds before Sowing.—Great gain in rapidity of sprouting, counting from the time of planting, may be expected as a rule, if seeds are previously soaked in water; and the longer the seeds are soaked, within reasonable limits, the greater is usually the gain in rapidity of sprouting. This fact is interesting, in face of the experience that very profuse watering after sowing gives an opposite result.—This gain in rapidity of sprouting in soaked samples is really fictitious, however, inasmuch as germination actually begins in the soaked seeds before the dry samples are sown. In truth, the soaked seeds are sown earlier than the dry ones. If this advance in period of sowing is added to the date of sowing of the dry seeds, it will be found that dry seeds, as a rule, sprout fully as early as soaked seeds, and many times much earlier.—Total amount of sprouting does not appear to be influenced by soaking.—Similar results are not to be expected from all species of plants.

Influences of Character of Soil upon Sprouting.—Variations in results of testing may sometimes be expected in consequence of character of soil in which the tests are made. In the present instance, low results in potting soil as compared with tests in sand, appear to be due to the greater amount of water held in the earth, causing the seeds to rot. The results may, therefore, be studied in connection with those upon the influence of varying amounts of watering.

Influences of Light upon the Sprouting of Seeds.—Very great differences in results may sometimes be expected between samples exposed to light during the process of sprouting, and those kept in darkness.—When such differences occur, they indicate that light retards or even wholly prevents germination.—In some species this influence of light is greatly marked, while in others it is not apparent.—It is apparent that those apparatuses which test seeds by holding them on a porous plate above water, are to be looked upon with distrust, unless provided with an opaque covering; and even then they may prove unsatisfactory, as the experience with the Lark-pur seeds indicates that best sproutings follow planting in the soil.

Weight of Seed in Relation to Sprouting.—Variations in results of testing, both as regards rapidity of sprouting and the total amount, they may be expected between seeds of different weights in the same sample.—This variation is much greater in some species than in others. In our tests the variation was particularly marked in Cabbage, Radish, Sweet Pea, Bean, Gesse, (*Lathyrus sativus*), Burnet (*Poterium sanguisorba*), Martynia, Orach.—As a rule, the heaviest seeds in any sample give earliest and highest results.—In some cases, the lightest seeds in the sample give earliest and highest results, apparently because the heaviest seeds, with which they are compared, are over-ripe; or, in some instances, under-maturity may result in earlier germinations, and such seeds are sometimes light in weight.

Colour of Seed in Relation to Sprouting.—Seeds which differ widely in colour in any sample frequently give different results under test.—This variation in results may lie in greater rapidity of sprouting, or in higher total amounts, or in both.—The relative values of seeds of different colours vary with each species, or sometimes with each sample.

Influences of Latitude upon the Sprouting of Seeds.—Northern grown corn appears to germinate more quickly than Southern grown corn.

Variations in Duplicate Tests under Like Conditions.—One test cannot be accepted as a true measure of any sample of seeds.—Variation in duplicate tests is likely to be greater when seeds are planted in soil than when tested in some sprouting apparatus like the Geneva tester.

Comparisons of Results of Seed tests with Results of Actual Sowing in the Field.—The table indicates that actual planting in the field gives fewer germinations than careful tests in conditions under control. This difference in total of germination, even under favourable conditions of planting, may amount to over 50 per cent.—In planting, due allowance should be made for the comparatively bungling methods of field practice by the use of greater quantities of seeds than would seem, from the results of tests, to be sufficient.

GENERAL SUMMARY.

1. Variations in temperature may cause variations in rapidity of sprouting.
2. An essentially constant temperature of about 74° gives quicker results than an ordinary variable temperature of a similar mean.
3. It is probable that any constant temperature gives quicker results than a variable temperature of which the mean is the same as the constant temperature.
4. As the mean temperature lowers, sprouting, as a rule, becomes slower.
5. In some instances, greater rapidity of sprouting due to a constant temperature of 74°, does not appear to be correlated with greater per cent. of total sprouting. In Beans, however, greater per cent. of sprouting appears to follow greater rapidity of sprouting.
6. There is probably a tolerably well-defined optimum temperature for each species of plant, in which best results from seed-tests can be obtained. This limit is not closely determined for most garden seeds.
7. The quantity of water applied to seeds may determine both the rapidity and per cent. of sprouting.
8. A comparatively small amount of water gives quickest and largest results.

9. Greater quantities of water than are required for best results, lessen rapidity and per cent. of sprouting either by causing the seeds to rot, or by retarding germination, or by both.

10. The soaking of seeds in water before planting does not appear to hasten sprouting, if the planting time is reckoned from the time at which the seeds are put to soak. But if planting time is counted from the time of placing the seeds in soil, quicker sproutings are the result; this method of reckoning is incorrect, however.

11. The soaking of seeds does not appear to influence the total amount of sprouting.

12. The results of soaking appear to vary in different species.

13. The character of soil in which the test is made may influence the results, both in rapidity and per cent. of sprouting.

14. Light has great influence upon the sprouting of the seeds of some species.

15. When light has any influence, it retards or wholly prevents sprouting.

16. The effects of light upon sprouting are different in different species.

17. The weight of the seed is often a tolerably accurate measure of its viability, as determined both by rapidity and per cent. of sprouting.

18. As a rule, heavy seeds germinate better than light ones of the same sample.

19. Seeds of different species may vary in sprouting in reference to weight.

20. The colour of the seed in some cases is a tolerably accurate measure of rapidity and per cent. of sprouting.

21. When there is any variation in viability in reference to colour, it is usually found that the stronger sproutings occur in the darker coloured seeds.

22. The relative value of seeds of different colours vary with each species, or sometimes with each sample.

23. The latitude in which seeds are grown may determine their behaviour in germination.

24. Northern grown corn appears to germinate quicker than southern grown corn. It is to be expected, from our knowledge of the variation of plants in reference to latitude, that seeds of most species will give similar results.

25. Variation in results of seed-tests may be due to the apparatus in which test is made.

26. Those apparatuses in which the seeds are exposed to light are to be distrusted.

27. Those apparatuses which afford no protection to the seeds other than a simple layer of cloth, paper, board, or similar cover, are usually unsafe, from the fact that they allow of too great extremes in amounts of moisture.

28. The so-called Geneva tester appears to give better results of sprouting than tests made in soil, probably from the fact that moisture and temperature are less variable than in the soil tests.

29. In order to study germination to its completion, tests must be made in soil.

30. Tests made indoors are more reliable than those made in the field.

31. One test cannot be accepted as a true measure of any sample of seeds.

I. The results of a seed-test depend very largely upon the known conditions under which the test is made.

II. Results commonly vary between tests made under apparently identical conditions, even with selected seeds. Therefore—

III. The results of actual ordinary planting in the field cannot be considered a true measure of the viability or value of any sample.

IV. Rapidity of sproutings, unless under identical conditions, is not a true measure of vitality or vigour of seeds.

V. There appears to be no pernicious adulteration of garden seeds in this country, and, as a rule, the average hurtful impurities

In the ordinary farmer's garden seed-testing is perhaps of little or no value, but to the market gardener, who plants considerable areas to special crops, and to the seedsman, it is highly profitable. It is possible that in some cases the character of the crop can be prognosticated with some degree of certainty

from behaviour of plants in germination, wholly aside from percentages of sprouting. The studies of experts in this country and Germany, indicate that when accurate information is desired as to the value of seeds, the seed-test should present at least the following data: Name of variety; where grown; when grown; how kept; per cent. by weight of foreign matter; per cent. by weight of apparently good seeds; nature of foreign material; weight of seeds; manner of testing; number tested; average and extreme temperatures during trial; first germinations in hours; last germinations in hours; per cent. by number germinated; per cent. unspouted but sound at end of trial; date of test; estimate of agricultural value.—L. H. BAILEY.—*Gardeners' Chronicle*.

THE ENCOURAGEMENT OF RURAL INDUSTRIES.

The Government of Victoria being embarrassed with the magnitude of the surplus, has conceived the idea of appropriating a quarter of a million pounds sterling during the next five years to the encouragement of certain rural industries. The principle of aiding the development of such industries is in the abstract sound; the intention is laudable, the work of tilling the land, and raising food of various kinds therefrom, being the normal business of man. It is probably not forgotten that farmers pay heavily through the Customs for nearly every article they have to buy, and it has been suggested that the scheme of giving bonuses for the varied form of industry enumerated is put forward as a partial return of the moneys extracted from the farmers' pockets. It is proposed that acreage bonuses be offered to persons who shall plant and cultivate during the year 1889, or during the succeeding four years, Grape-vines, fruit trees, and such other trees and shrubs of commercial value as may be approved by the Governor in council, in sums not to exceed £2 per acre, divided as follows:—£1 per acre at the end of the first season, viz., from November 1 to February 28; 10s. per acre at the end of the second season; and 10s. per acre at the end of the third season. Bonuses not exceeding £3 per acre are also proposed for certain acreages of a variety of fruits, commencing with 5 acres each of Apples, Almonds, Apricots, Chestnuts, Figs, Filberts, Gooseberries, Loquats, Lemons, Mulberries, Nectarines, Peaches, Olives, Quinces, Strawberries, Walnuts, and Carob trees $2\frac{1}{2}$ acres, 2 acres, and 1 acre, being required of numerous other sorts; the payments to be made by instalments in much the same manner as in the previous instance, but extending over five years. For the making of wine of approved character the amount paid is not to exceed 2d. per gallon; no one maker to receive more than £100, while a bonus not to exceed £5000 may be paid to any company with a capital of not less than £100,000, of which £25,000 shall be fully paid up, and successfully established, to purchase, store, blend, and export wine. Exportation bonuses are also provided, and amongst the objects of these are green, dried, bottled, and canned, fruits.—*Gardeners' Chronicle*.

CEYLON AND AWARDS AT THE PARIS EXHIBITION.

It would be unwise to assign too great importance to the fact mentioned in our London correspondent's letter by last mail that our locally grown teas have found no mention in the list of awards made by the Commissioners of the Paris Exhibition. It is true we might have expected to find that under the heading of "*Articles Alimentaires*" honorable mention at least would have been made of our teas; but we have searched that list in vain to discover any reference to teas of any description or growth. If, therefore, any soreness may be felt at the absence of any mention of our own product, some consolation may be derived from the fact that we have suffered in good Company.

But any dissatisfaction that may be, in spite of such a consideration, entertained, should be discounted by the further fact that that feeling seems to be very widespread among a large number even of exhibitors of French nationality. Although we have seen it stated that there was a total number of—roughly speaking—44,000 exhibitors only, some 33,000 awards have been distributed among them. Those who have not been fortunate enough to secure them have held several meetings to dispute the justice of the verdicts of juries and of experts, the attendance at such meetings having been confined to native exhibitors. It is evident therefore that the findings determined upon have given rise to much of discontent, and it will only be natural if that feeling be shared in by ourselves. But the result in our own case may not improbably be due to the very limited interest felt by the French in the consumption of tea. All the evidence adduced goes certainly to show that, at present at all events, tea drinking is not a national taste in France. Whether it is ever likely to become so, is, to say the least, extremely doubtful. But it has been mentioned to our London correspondent by Mr. Haldane of Shand, Haldane & Co.—and his observations have been confirmed by those of others—how materially public tastes among the French have changed of late years. Whereas but a few years ago beer was an almost unknown beverage in France, Mr. Haldane remarked that scarcely anything else is now consumed at the so-called *cafés* of the Parisian boulevards. The versatility with which the French people as a nation have ever been credited seems not unlikely to mark its successive appreciation and discarding of customary beverages. The love of change may produce in this respect as great revolutions with respect to national alimentary tastes as it has done in regard to national political institutions. It will not be surprising, therefore, if some day or other we may hear that tea has taken the place of the beer which seems now to have ousted altogether the light wines until recently so dear to, and so exclusively drank by, the *habitués* of the Paris pavements.

But meanwhile the limited patronage granted to our tea-room during the course of the Exhibition, and the subsequent entire ignoring of the article by its jurors, sufficiently prove that as yet there is little ground for any expectation that a fuller appreciation of tea is likely to develop. Indeed we read that a sort of crusade is being preached against the use of tea in France. That that crusade is being supported by the most fallacious and ignorant of arguments, we can realize from the assertion made that the use of tea among our own countrymen lies at the root of the evil of our large national consumption of alcoholic liquors. We very much fear that the tastes which lead to this latter regrettable fact were established among us long antecedent to the introduction of the fragrant leaf from China. At a date centuries before tea was vended as a curiosity in England at prices ranging from ten shillings to twenty-five shillings a pound, beer was the established national beverage of the English people. We read that Queen Elizabeth took her morning draught of ale with due regularity, and we do not doubt it was no stunted potation that "Good Queen Bess" indulged in. Then the commissariat of both the army and navy of her days had a serious difficulty to contend with which often delayed the setting forth of fleets and the march of troops which has little or no parallelism in the military catering of the present time. It is recorded that the daily allowance of beer to both soldiers and sailors to be provided for was thirteen pints per diem! In the face of such historical facts, what becomes of the theory that upon

tea must be cast the responsibility for the love of alcoholic liquors which is common to all peoples inhabiting the colder climate of the north.

Other climes have other customs, and whether it may be possible to graft among peoples less exposer to vicissitudes of climate than are those of the more northern regions of Europe the tastes for milder forms of stimulant which is, we are happy to think, now succeeding in great part to the coarser tastes of a former generation, remain yet to be seen. Tea undoubtedly supplies to the nervous system much of the excitation formerly sought to be derived from alcohol; but without being followed by the disastrous physical and moral deterioration produced by undue indulgence in the lastmentioned. This fact yet remains to be realized by our French friends; but the very strength of the crusade against the innovation would almost seem to show—by the extravagance of the arguments employed—as if the thin end of the wedge had been introduced to the extent at least of rousing opposition and fierce and unjustifiable denunciation.

Much of the prejudice and the insensate abuse of tea, however, are doubtless due to the fact that the product is now so largely grown and manufactured and sent into the markets of the world by the capital and enterprise of "perfidious Albion."

FRUIT DRYING.

Among the prominent objects which were to be seen at the Windsor show of the Royal Agricultural Society last June, was the fruit-drying apparatus of Ph. Mayfarth & Co., of Frankfort-on-the-Maine, Germany, and 16, Mining Lane, London, E. C. the apparatus was awarded the 1st prize at the show in question, and it consists of a mantle-oven furnace, connected with the drying-shaft, which is elevated at the end, so as to ensure a better circulation. The fruit to be desiccated is placed on wire trays, which are then introduced to the oven, which is in two chambers, and each capable of receiving two or three series of trays. We have seen samples of Gooseberries, Cherries, Apples, Pears, Currants, Cabbages, Leeks, &c., dried by the apparatus, and the results appeared in each case satisfactory. The apparatus is constructed in six sizes.—*Gardeners' Chronicle*.

SHADE FOR COFFEE, TEA, AND COCOA.—The present time seems a period in which shade for all products is being widely tried. We hear of a Matala estate being planted up with *Sau* as a shade for tea; cocoa planters have long gone in for shade; and now coffee planters are purchasing *ficus glomerata* seed, and hope that the umbrageous shelter of those fig-trees will help to restore coffee to its old vigor and robustness. It will be very interesting to watch the effects of a more general cultivation of shade throughout estates, for the Ceylon planter of the olden days was generally very averse to shade of every kind, believing that it affected the yield of crop. If we are to believe the stories we have heard of the wonderful effects of the *ficus glomerata*, coffee under it is benefited so conspicuously as to suggest that this good result is due to some effect which the roots of the shade tree must have upon it. The mere shade afforded cannot account for this, as it is difficult to believe that the shade cast by one tree differs, except in intensity, from that thrown by another, and planters are very largely of opinion that there is some special virtue in the *ficus glomerata*. We are led, therefore, to suppose that this is derived from the roots of the tree in opening up the soil and in absorbing qualities harmful to the coffee, or in giving forth properties of benefit to it. Altogether the subject is very interesting, and we should be glad of further information on the matter.—*Local "Times."*

VICTORIA REGIA.—In compliance with a request from the Manager of the Botanical Garden, Hakgala, Ceylon seeds of *Victoria regia* were forwarded, together with the following hints as to their treatment:—

"The seeds should be sown in a small flower-pot, and placed about an inch under water in a large pot. When the leaves of the seedlings are about 3or 4 inches broad, re-plant each in a basket filled with good soil, and, after a fortnight or three weeks growth, plant them out finally, basket and all, in the tank where they are to remain. Occasionally the seed takes some time to germinate, but, so long as the seed remains hard, it is all right."—*Proceedings of the A. H. Society of Madras.*

PEPPER CULTIVATION.—We understand that pepper cultivation on the Kodacherry Hills has not been a failure. A year ago a German gentleman of this station—highly respected and well known in social circles—had taken up lands on the Kodacherry Hills, to try experimentally the cultivation of pepper. A young gentleman who was placed to superintend the plantation, and with whom we have had an interview, informs us that a small crop was obtained this year. As the pepper vine will mature only after a few years, we expect a handsome crop will be harvested, in the course of a few years, and the concern worth a decent value. We wish the undertakers every happiness, and hope success will crown their endeavours.—*Cochin Argus.*

THE MAGAZINE

OF

THE SCHOOL OF AGRICULTURE,

COLOMBO.

Added as a Supplement monthly to the "TROPICAL AGRICULTURIST."

The following pages include the contents of the *Magazine of the School of Agriculture* for December:—

THE REPORT OF THE SCHOOL OF AGRICULTURE

(Read before H. E. the Governor.)

It is nearly 6 years since the Colombo School of Agriculture was opened in January 1884, and at this its second public prize distribution, I have to repeat the pleasant duty of a past principal and heartily welcome Your Excellency and thank you for the honour you have done us in coming here today to distribute certificates and prizes to the successful students. On the former occasion, Your Excellency expressed the hope that at some future date your successor would hear of the success of the students who have passed out of this school. It has so fortunately occurred that this success can be reported during Your Excellency's own regime, and it is a source of gratification that the work which was initiated by the present Director of Public Instruction, aided by the great influence of Your Excellency's own approval, is able to show proof of its usefulness to the people for whose good it was intended, within the period of Your Excellency's rule, in spite of many influential prophecies to the contrary. Since my arrival in the island in February of this year, my experience has led me to believe that there could not have been a happier idea than that of the D. P. I. in initiating the work of agricultural reform with which his name will always be associated and that whatever the opinions to the contrary, that reform is gradually working its way among our agricultural classes to their material benefit. Both from the reports of our agricultural instructors, as well as from private communications and personal observation, I am led to believe that the apathy and even active opposition which originally meet the progress of improved methods of cultivation are steadily and surely giving way to a more liberal spirit,—a fact which it must be admitted is a source of great encouragement to all those connected with this work. The records of experiments at this school, as well as the reports from

experimental stations at Toppur, Panapitiya, Minuwangoda, Mullaittivu, Galle, Akmimana, Nikaweratiya, and other places, not only from our instructors, but from headmen (and more especially from the President of Tihagoda in the Matara district), have all been published, and I need not detain Your Excellency with them. Now as to figures, beyond reminding you, sir, that they all bear witness to the great success of the improved method over the old system of paddy cultivation. The sending forth of men who have for two years had the scientific principles of agriculture explained and illustrated to them, is bound in time to influence the minds of those among whom the students will move and work; and turn them to see the need of improvement in certain of their agricultural operations; while the practical proof shown on the spot of a double crop always, and sometimes a still more largely increased yield, emphasises any mere teaching. During the past session, four additional classes have been added to the curriculum, viz., veterinary, entomology, geology and field-surveying. These are of an elementary nature, and deal with the subjects only so far as they can benefit the classes from which the students spring. For I consider that the more one knows of the different aspects of his work, the greater is the interest and enthusiasm he will evince in the thorough performance of it. A practical knowledge of veterinary is, I think, of the first importance to agriculturists in a country where cattle are so fully utilized and where so much loss results, almost annually from the so-called "cattle murrain," which is mainly caused by the want of the knowledge of a few simple facts relative to the proper feeding, housing, and treatment of stock. A knowledge of entomology will be no less useful in a tropical country such as ours, where every circumstance seems to favour the development and spread of insect-life which is year by year, whether in the case of paddy, coconuts, or what not a serious hindrance in the way of successful cultivation, I should

also mention that two of our students were selected by Col. Clarke as Forest Rangers, and the knowledge of Botany, soils, and entomology imparted here is of great use towards the requirements of the Forest Department. The practical work of the school is still carried on under the able supervision of Mr. A. W. Jayawardene, who was, as is known to Your Excellency, trained at the Saidapet Farm in the Madras Presidency; and the willingness and zeal displayed by the students in doing their own share of the work with their own hands were an agreeable surprise to me, and are undoubtedly a healthy sign, considering the dislike to manual labor previously exhibited by well-born natives, and with which the D. P. I. had originally to combat. During the year the school lost from the staff of its masters, the valuable services of Mr. Lewis, who was promoted to a Sub-Inspectorship of Schools, but it has gained a useful helper in the person of Mr. W. A. De Silva (who lately reflected on the School, the honour of winning the open prize offered by the "Independent" newspaper for the best essay on "cotton cultivation.") There are up to date 10 agricultural instructors in various parts of the island, six of whom are paid by Government and 4 privately. The valuable encouragement given, and the great interest shown by more than one Government Agent, in the pushing on of agricultural work, is a matter of congratulation. Many of our instructors have carried on experiments with other products than paddy, with a view to impressing on native cultivators the possibility of their cultivating these products remuneratively. The success of Mr. Rodrigo's arrowroot cultivation, and Mr. Lawrence Perera's cotton cultivation are worthy of mention; while experiments with dholl by most of the instructors have proved that a wholesome and nutritious food-stuff can be produced with little trouble. With the multiplication of crops capable of successful growth by the natives of the island, there will obviously be less risk to our cultivators, while the resources of the soil will be taxed to a less extent. A new feature in the means of diffusing agricultural knowledge is the "Magazine of the School of Agriculture" which was started in July last, and is still spread after a six months' term of probation to live, it is hoped, a long and useful life. There are both an English and a Sinhalese edition, and from the manner in which the publication has been received and encouraged by landowners and others, I am sanguine of its object,—to circulate useful information among the agricultural classes—being realized. I have again to thank Your Excellency for the honour of this visit, and to hope that still more substantial success—even such as will eventually tend to elevate our cultivators from their present precarious condition to a securer position—may yet have to be reported to you.

HOW DOES SCIENCE HELP AGRICULTURE VI.

BY C. DRIEBERG, B.A., F.H.A.S.

One of the drawbacks, and very often the greatest drawback, in the way of successful cultivation is th

damage done by insect pests. Instances are innumerable of insects causing whole-sale destruction of crops, and bringing utter ruin to cultivators. In Europe and America, the Turnip and Hessian flies, and the Colorado beetle, have been the great enemies of farmers, and no trouble and expense have been spared in the investigations into the nature and habits, and the best means for the destruction of these pests. Commissions have been appointed to enquire into the subject, and scientific men have devoted their attention solely to these enemies of farmers. The science which deals with the classification, life-history, and habits of insect-pests is entomology, and closely connected with the subject is the name of Miss Eleanor Omerod, who holds the post of consulting entomologist to the Royal Agricultural Society of England. Miss Omerod's valuable reports are published in the Society's Annual Journal, and she is also the author of works on the insect pests not only of England but of certain colonies, which are considered standard books of reference on the subject.

Considering the vast destruction which insects are capable of bringing about, it is most desirable that the insects of every country which are known to be destructive to vegetation should be studied in regard to their habits and modes of propagation, with a view to their being dealt with most effectually when necessity demands. It is a healthy sign that the study of the subject of entomology is beginning to be encouraged in Ceylon, and that knowledge is being circulated by means of the Newspaper press, so that cultivators may know as much as possible about the enemies with which they have to contend. A work has lately been published in India on insect-enemies, and will be found to be of great value to agriculturists. Some of the pests dealt with are such as do much damage in our own island, but there are a number of other destructive creatures in Ceylon which have yet to be studied. Many of them with no distinctive names; and observations with regard to which must reveal facts that are certain to be of great benefit to our local agriculturists. The pests which attack tea and coffee have been and are being studied by capable persons, and it is to be hoped that the insects which infect other crops than these, and especially paddy, will not escape observation, and will in time be dealt with. More knowledge regarding these latter is much required before any remedial measures can be adopted. In a country with a climate such as ours, circumstances and surroundings are far more favourable to the development and spread of insect than in more temperate regions. The abundance of insect-life is indeed one of the striking characteristics of tropical countries to those who come eastward for the first time. Warmth, dense vegetation, and uninterrupted verdure, all these go to favour insect-life.

Thus it is all the more necessary that the life and habits of tropical insects should be studied. For cultivation may often be regulated according to the periods during which particular insects appear in their destructive form, so as to—so far as is possible,—delay

the crop, strengthen it to withstand the attack, or "rush" it past the critical stage when it is most open to insect ravages.

Again in some instances such mechanical operations as ploughing, harrowing, and rotting at particular periods, and chemical means such as application of slaked lime, gas-lime, soot, &c. are of inestimable benefit where intelligently adopted.

Draining of wet places is very necessary, as excess of moisture helps insects to thrive while the crops are kept in low condition. All weeds, stubble, and unnecessary growth of shrubs should be cleared off the land and from fences and ditches, and the cleanings burnt, as pests generally find shelter in such places. Manure heaps and collections of vegetable refuse are commonly frequented by insects as convenient places for laying their eggs, so that it would be a safe precaution to throw quick or gaslime over such heaps. Sometimes it is necessary as in the case of the wireworm attack in England to adopt a rotation, and bring in a crop which is no favourite of the pest, thus clearing the land of them periodically.

Very often cultivators recklessly resort to costly methods of ridding their crops of pest, when convenient and inexpensive means suffice. In some cases it is necessary to resort to insecticide-sprays, and in this connection the invention of Mr. Strawson patented as "The Strawsoniser" is worthy of mention as the most perfect machine of its kind for the distribution of insecticides.

What we want before all, however, is reliable information with regard to the insects themselves. Easy means of identification, and a better knowledge of their feeding and breeding peculiarities. From the attention the subject is receiving in more than one quarter, there is no doubt that before long we shall be able to have this information as regards not only coffee and tea-pests, but those of cotton and paddy and all the crops of large and small cultivators, in a collected form, convenient both for circulation and reference.

COTTON. V.

By ABA.

About a week after planting the cotton seeds germinate and expand their basal leaves. After two weeks the vacancies where the seeds have failed to grow should be replanted. When the plants are from three to four weeks old, the land should be cleaned by removing especially the weeds growing round the young plants by the hand. If the weeds are allowed to remain the growth of the cotton is very much retarded, therefore the operation of weeding should not be put off. An important fact to be kept in mind with regard to weeding is to do it before the weeds have flowered and seeded, otherwise they will make a rapid growth again by means of the seed shed in the soil. Another evil is that weeds harbour, and act as breeding grounds for insects, which are injurious to the growing crop.

When the plants are about a month or six weeks old, the soil should be loosened by digging with a mamoty or some other suitable implement. There are a great many advantages to be derived by this operation. For example, it facilitates the growth and distribution of roots, removes an excess of moisture when present, and increases the absorptive properties of the soil. It adds to the store of plant food, and improves the material in the soil by exposure to the sun and the atmospheric agencies. Another material benefit to be derived by digging the soil is the destruction of weeds.

When the cotton plants are nearly four months old and are ready to flower, the soil should be again loosened and the earth drawn up to the roots of the plants. Not only are the roots strengthened by this process, but a good deal of nutritive matter is brought within the reach of the plants, thereby helping to increase the numbers of flowers, and hence the produce too.

When a perennial cotton, such as the Kidney, is cultivated, after each plucking all the green wood should be removed, when the plants put forth new branches and bear very much better during the next season.

(To be continued.)

PADDY CULTIVATION AND TRANSPLANTING.

V.

By W. A. DE SILVA.

(Continued.)

Irrigation.—In my last I dwelt on the subject of irrigation without taking into account its actions regarding the increase of fertility in soils. The quantity of water necessary for the proper growth of a crop was discussed at length, and the minimum, that is a supply of 7 weeks was found necessary in the case of transplanted paddy. This quantity is quite sufficient to act mechanically, and as will be seen hereafter, it is more than enough regarding the increase of fertility in a soil. It cannot be said that the more water we have, the advantages too will be more. All the advantages may be brought about by a certain limited supply, and more than that supply would either be powerless to be of any additional service or might act injuriously.

Water used in paddy cultivation acts beneficially in four ways, besides being mechanically useful. First, it brings along with it earthy particles or matter in suspension, and enriches the soil by depositing them. Secondly, it brings substances held in solution. Thirdly, it aids in the solution of plant food in the soil. Fourthly, it enters into the composition of plants, and improves the temperature of soils and distributes manure. Under the first condition, the addition of silt, the fields depend more or less for an addition of such matter, on the nature of the water used in irrigation. In Ceylon, fields are irrigated from water obtained from different sources, rain water which flows

down the highlands, river water got by impeding the progress of steams, and tank water, which is the water obtained from rain and rivers, but stored up for use when required. The other method of obtaining water, that is, by means of wells, is not used here, as far as I have observed, for the purpose of irrigating paddy fields. Water got from the rainfall in its course of flowing over highlands brings with it a deal of matter in suspension, and when it has settled down in the lower grounds (the fields) generally deposits a layer of mud consisting of materials brought from the adjacent highlands.

River or stream water is generally clear except in very rainy weather (though there are exceptional cases) and does not carry much silt without depositing it on its way, except when the streams are flowing at a rapid rate. But ordinarily the water got by the impeding of streams contains very little matter in suspension, and hence very little silt is added; whilst that from tanks generally contains hardly any silt, because the water when stored up deposits all the matter which it holds in suspension.

Thus, with regard to the addition of silt we have the rain water standing first in regard to its advantages. But it is not silt alone which adds fertility to a soil. The substances brought in solution are more active in this respect and their action is quicker.

Water has remarkable soluble properties, and dissolves substances on its way. Thus rain water will dissolve substances as it flows, and the dissolving action is promoted by the gases and acids which it has obtained from the atmosphere and soil. River-water dissolves substances generally occurring in the bed of the rivers, and the drainings it gets on its way down contribute some disordered material, while tank-water contains as much if not more matter in solution as the other two descriptions, the stability of the water not effecting the matter in solution. Sometimes this description of water is more enriched with matter in solution on account of the constant evaporation which it has to undergo by exposure.

It will be thus seen that water should first come in contact with the materials themselves so as to dissolve them, and that the amount of materials depend to a great extent on the nature of the places the water has to pass through. The determination of matter held in solution in water would be very interesting and useful to the paddy cultivators who could by that means be guided as to the amount of material with which they are supplied through that agent.

We now come to the other actions of irrigation water; viz., the dissolving of plant food found in the soil, and the entering into the composition of plants themselves. These two processes are more or less carried on under all circumstances whether the water be obtained from tanks or supplied by the rain. Thus the uses of water in paddy-cultivation are manifold; and for the highest benefits, a knowledge of its advantages and the best means of utilizing it are necessary.

CEYLON BEE CULTURE. I.

BY ABA.

The first native of Ceylon who attempted anything like bee-keeping on improved methods was the late Samuel Jayatileke Mudaliyar of Kurunegala, and an interesting paper written by him in 1881 is now lying before me.

The Mudaliyar got out with the aid of several English gentlemen beehives &c. from England, and endeavoured to improve the primitive means adopted by the natives, but with very little success, as the native bees could not be induced to build their combs in the imported hives. Mr. Jayatileke attributes this, to use his own words, to "want of ingenuity and experience to adapt the frames to their mode of comb-building, or to the bees preferring pots, which are cooler than the boxes."

However the old Mudaliyar was able to show visitors at Roselane Cottage, with no little pride, a colony of Cyprian bees which he had in English hives in a quiet corner of his garden. I remember Mr. Andree of the Kurunegala Land Registrar's Office showing me a swarm of the *Mi Messa* building their combs inside an old gin case which he had improvised into a respectable-looking hive.

Bee-keeping with the natives is carried on in the most primitive manner. An ordinary water pitcher or *kalagediya* which has become unserviceable is placed after smearing the mouth with a little honey in an elevated portion (generally on a flowering tree) in some retired spot in the garden during the swarming season, which is in March and April. A swarm of bees may by the merest chance enter this primitive hive and build combs and stock the cells. When the proper season, which is in July or August comes round, the bees are driven away by smoke and the pitchers broken. All the honey is abstracted and the brood combs are thrown away causing considerable destruction of bee-life. But the greater portion of the honey used in Ceylon is obtained by bee hunters from the crevices and hollows of rocks and trees in the jungles where the wild bees build their combs.

I am induced to write this article on apiculture (which will be continued in the future numbers of the Magazine) with the hope that my countrymen will endeavour to open up an industry, so easily conducted, and which will not fail to yield a good return if properly carried out.

(To be continued.)

INDIGENOUS: FOOD PRODUCTS: CULTIVATED AND WILD. III.

BY W. A. DE SILVA.

Portulacaceæ.

6. *Portulaca Oleracea*. L. Purslane, known among the Sinhalese as Genda. This is an annual potherb, both cultivated in gardens and growing as a weed in cultivated places. When growing wild, it is always found in such places having a fertile soil, either newly manured or otherwise, and is very seldom or never found in barren grounds.

The leaves are of an obovate shape, and the whole plant, growing into several branches, is very succulent, having a watery crystallized appearance throughout. The flowers are small; and seeds minute and black. The branches and leaves are very tender and easily severed from the stem, which too readily breaks at the nodes, the whole plant having very little fibro-vascular tissue.

The plant is used in food prepared in several ways and is relished much. It is made into curries and also salads. It has, when made into curries, a slight acid taste, which is by no means disagreeable.

Portulaca is considered to be a very cooling vegetable, and hence there is a prejudice amongst some people against using it. Vegetables of cooling properties are generally objected to perhaps on account of the supposition of their being promotive of the "windy humour."

The other two kinds of Portulaca, commonly found growing wild and never cultivated, viz., *Portulaca, Quadrifida* and *Portulaca tuberosa*, the Keen Genda and Uru-Genda of the Sinhalese are occasionally used in curries when found in sufficient quantity to be gathered. The plant *P. Quadrifida* has a thread, like stem and branches, and very small leaves, all creeping on the ground; and the leaves have a reddish tint, and are succulent. The other kind, *P. Tuberosa*, resembles very much the ordinary kind, described before, but the leaves and stems are of a blackish tint, and the nodes are much swollen.

All the three species are used medicinally, and they have very cooling properties. The native Medical Practitioners use the bruised leaves with success in cases of burns and scalds, and the juice of the plant is considered to be a refrigerant and stomachic. The whole plant is used for diseases supposed to arise from a bilious condition.

Portulaca Oleracea, though not widely cultivated is a favourite plant amongst market gardeners near towns as they always fetch a reasonable price, and are saleable at all times.

OCCASIONAL NOTES.

THE SWEET POTATO.—Among the plants cultivated for the sake of their tubers in this country as food for man and beast the sweet potato holds the prominent place. The sweet-potato (*Battas Edulis*), Sinhalese Bataia, is a creeping or twining plant and bears showy light purple flowers. It is cultivated all over the tropics, but its original home is supposed to be the East Indies. The plant is grown in all parts of Ceylon, and next to rice and kakkan it yields the largest amount of valuable food to the natives of this country. It is greatly relished both by cattle and pigs, and both the tops and tubers are valuable as food for milch cows, as they increase the flows of milk. There are several varieties of sweet potatoes, such as Sini bataia; Kiribadu bataia; Ratu bataia; Sudu bataia; Murusi bataia; Lewandau bataia.

They can be grown in a light loamy soil with best results. Both the green tops and tubers are used for planting. In planting tubers they should be kept in a moist shady place till they give out young buds. Then they should be planted on ridges. The ridges should be 4 feet apart, and on each ridge the tubers should be planted in two rows 6 by 12 inches apart.

In planting green tops they should be cut into pieces not exceeding 10 or 12 inches, and these are planted as before described. Planting should be done in the months of April or May, and September or October. After planting the ridges should be covered with straw.

After 4 months the tubers are full grown and good for gathering. For gathering the creepers should be cut and removed, and the tubers dug up, taking care not to cut them.

The tubers can be preserved by burying in a dry soil and preventing them from being moistened. And also by packing the tubers in a box with dry sand and keeping in a warm place. Coldness or dampness causes immediate decay.

T. W. GOONEWARDENE.

HOW DECORTICATED COTTON CAKE IS MADE.—The cotton seed mostly grown in America, and from which the decorticated cotton cake is made is not clean and free of cotton, but is tightly bound round with lint. The main bulk of the cotton is picked off by the negroes, but the seed is afterward sent to the ginner, who give off a deal more cotton. It is now in a fit state to be marketable, a large proportion of the seed finds its way back to the land for manure, and the smaller proportion reaches the seed crushers. These gentlemen take off as much more cotton as they can by means of linters; the seed is thence passed over to the "hullers" which sculp clean off all the black husk of the cotton seed, together with any cotton remains, and leave only the kernel. The husks now proceed to the boiler fire; the kernels are ground, rolled, heated, and then put into the hydraulic presses, where the oil is extracted, and the decorticated cotton cake results. Owing to improved machinery the oil left in the cotton cake made in the new mills shows under 8 per cent, and the cake is left perfectly hard. The idea of extracting as much oil as possible from the seed is now considered to be by no means an advantage so far as the feeding value of the cake is concerned.

A NEW PLAN FOR TREATING SEWAGE.—This new method of treating sewage, known as the "Amines" process, consists in the mixing of Amines (a group of ammonia compounds) and lime with sewage. Herring-bone, a practically waste product, is used as the cheapest source of Amines. The promoters of this process have in their own words "abandoned, at all events for the present, the idea of getting a great profit out of the sewage," but claim that the "Amines" process renders the effluent water inodorous, sterile, entirely free from deleterious germ life or putrefactive elements—in fact innocuous to public health." The

procedure pursued in the treatment of the sewage is quite simple. As the liquid flows from the sewer to the land, where it is to be used as a liquid manure, it is mixed with a preparation of milk of lime and brine in given proportions. The mixture is then turned into pits where the lime precipitates the solid matter and effectually destroy all organism, while the brine deodorises the mixture. The offensive smell is replaced by a briny odour, and in the course of half an hour the clear water may be drawn off, leaving a residuum which may be placed on the land with beneficial effects, and without giving off nauseous fumes, even in the hottest weather. A practical demonstration of the process was given last month at the Wimbledon Local Board Sewage Farm, in the presence of a number of scientific men and sanitary officers of towns. The Lord Mayor of London also witnessed the demonstration. The process gave thorough satisfaction. Some 8 tons of sludge treated in the manner described, neither compressed nor dried, and having been under alternate sun and rain for a month, was found to be absolutely inodorous. According to Dr. Klein, the most careful and exhaustive tests have failed to discover any micro-organism in the samples submitted to him. The process is the invention of Mr. Wollheim, and has been patented by him. The cost of treating a million gallons of sewage by the process is said to be from £2-10 to £3. This invention must be looked upon as one of great value, as the question of treating sewage in an inexpensive way so as to render it innocuous and at the same time to derive some benefit out of the valuable fertilising material it contains has been so far unsettled. Many inventions have been put forward, such as mechanical and chemical filtration, distillation, precipitation, but they have all failed as being impracticable on a large scale or too expensive. Irrigation has been adopted to a large extent in continental cities, but it as a process that is limited in its applicability to certain crops. The "Amines" process has not this disadvantage, and since there can apparently be no doubt about its perfect innocuous qualities from a sanitary point of view—qualities which a good many sanitarians hesitated in allowing to sewage irrigation—it will no doubt recommend itself as an inexpensive and cheap way of dealing with sewage to many corporations.

INFLUENCE OF TREES ON RAINFALL.—The original source of rain-water supply is the sea, which sends to the land a tolerably regular annual store of moisture. When this falls as rain, either of two things may happen—the water may go away directly to the sea, or it may return to the atmosphere as vapour to be again precipitated as rain. The chance of its re-évaporation is determined by the speed with which it flows away. From a treeless region it rapidly escapes; in an extensive district of forest it may again and again pass from earth to air, and from air to earth. The columns of vapour, which may be often seen ascending from a dense wood, afford visible evidence of the effect of forests on rainfall. The air above the trees

becomes much cooler than it is in the recesses below the foliage. This heated air within the wood seeks to rise, and escapes in great columns wherever there is a wide gap between the branches; as soon as it attains the cooler level above, the moisture is condensed, and the air, before transparent, becomes charged with steam. To replace this ascending air, a broad current drifts towards the emerging streams of vapour, generally from the higher parts of the forest, where the air, owing to the elevation of the site, is cooler than in the lower levels. This repeated passage of the moisture from earth to cloud, and from cloud to earth greatly increases the amount of force which the rain applies, in its falling drops, to the earth's surface; but the rank vegetation protects the surface of the land from the erosion which the rain would otherwise bring about.

VETERINARY NOTES.

Hydatids in the brain of sheep give rise to the form of disease known by the various names of "sturdy," "gid," and "staggers." These constitute the cystic stage in the development of *Tania cœnurus*, a tape worm found in the dog. When the mature segments of the worm are expelled from the intestines of the dog, they fall in the pastures and are taken up by the sheep. In a short time the embryos which are contained in the egg in each mature segment find their way into the brain and become developed into hydatids. To prevent the disease it is obvious that dogs which harbour tape-worms should be treated with the remedies which destroy those parasites—for instance, dosing regularly with $\frac{1}{2}$ to 1 drachm of arca-nut: and it is especially desirable that when the head of affected sheep is cut open by the butcher, and the hydatid taken out, it should be burnt or otherwise effectually destroyed, instead of being laid about to be picked up and swallowed by a dog, which would thus become infected with tape-worms. The cystic worm—the scolex stage—of the tape-worm in the dog is known as *cœnurus cerebrealis*, so called since it passes this stage in the brain of sheep.

The remedies are of more consequence to owners of lean stock, than to those who can send an affected animal at once to the market as "fat" without much loss. An animal cured of "sturdy" is none the worse afterwards for breeding purposes. The seat of disease is the surface of the brain, at its base or in the "lateral cavities." These cavities are situated one on each side of the forward brain, and there, in common language, a "water bag" grows, containing many young tapeworms. This spreads against the brain, causing absorption of that organ, with usually a thinning and softening of the skull in one or other of the hollows on the crown of the head, immediately in front of a line drawn between the ears. There the skull is very thin. Partial paralysis results, and the sheep gets blind on, and turns to, the side to which the "water-bag" inclines. Boring with a trochar and canula to extract

the cyst is easy in this case. When the seat of disease is far back in the brain the skull is thicker over it and there is not sufficient time, until death would occur, for the bone to absorb and become soft. Piercing then leaves little fractured pieces of bone from the skull on the surface of the brain, which although the disease is cured, cause suppuration, and death some days after. Principal Williams of Edinburgh recommends the use of the trephine, a little circular saw, to remove a minute piece of bone. The skin is bared from the skull immediately over the spot to which the movements of the sheep direct, and all detached pieces are washed carefully out before the external covering of the brain is broken. Piercing in the usual way to reach the cyst is then done with comparative safety. The manner in which the location of the cyst influences the movements of the sheep is peculiar and striking. If the cyst is situated on the right side of the brain the animal keeps turning in the opposite direction, and *vice versa*; while if it is situated about the middle the animal walks forward with its head elevated in an imposing manner.

I have referred to this parasitic disease as I am informed it occurs among sheep in Ceylon.

C. D.

WAYS AND MEANS.

PRESERVING EGGS.—Packing in salt will preserve eggs, but the salt preserves a certain portion of the white of the egg, leaving a small cavity in the shell. Another method is, to three gallons water mix a pint of newly-slaked lime and half a pint of salt, then put the eggs carefully into the composition. The lime process was patented many years ago by a Mr. Iague of Leeds. Eggs are also preserved by the shell being rubbed over with some grease or butter. It is found that preserved eggs are not so satisfactory when cooked in their shells as more recently laid eggs, although perfectly good for cooking and pastry purposes.

HOW TO GET RID OF RATS.—Scatter in the corners of the floor and every crevice in which a rat might go crystals of green copperas, and the rats and mice will disappear, the *Scientific American* says.

TO PREVENT WOOD FROM SHRINKING.—Wood well saturated with oil when put together, will not shrink in the driest weather. Wheels have been known to run for many years, even to wearing out the tyres. Boiled linseed is the best for general use, but kerosine oil is also very good.

CEMENT FLOORS.—A good cement floor may be made by mixing together just like ordinary mortar, one bushel of cement, five of clean sand, and two of fine gravel, broken bricks or stones. Cover the floor with this preparation to a thickness of from 3 to 6 inches; leave a week or ten days to harden, when the floor will become as hard as a rock.

LOOSE SCREWS.—It is a common thing when a screw or staple becomes loose to draw it out, plug up the hole

with wood, and then reinsert it. But screws and staples so secured soon come out again. It has been found that a much better way is to fill up the hole tightly with cork. Screws and irons so secured will remain perfectly tight, just as long as when put into new wood.

GENERAL ITEMS.

The agricultural students of the Edinburgh University are evidently getting the pick of the appointments as lecturers in agriculture. We have already noticed the appointments of Mr. Somerville to the chair of Forestry in Edinburgh University and of Mr. Middleton to the Professorship at Baroda. Since then Mr. Gilchrist and Mr. Leddingham have been appointed to Lectureships at the University College of North Wales, and the Tamworth Agricultural College and Training Farm, Warwickshire respectively.

The following reference to paddy-cultivation in Sabaragamuwa is taken from the *Ceylon Observer*:—
 "With reference to the recent discussion in your columns about paddy cultivation, I can assure you it is a source of trouble from the day the seed paddy is sown till it is secured in the granary in Sabaragamuwa. (1) The field has to be fenced to keep out cattle and wild animals during the day, the water has to be turned on and off at night, the villager has to watch it for fear of pigs and other animals. (2) When the ears begin to form and come to maturity, the cultivator has to go over the whole field every morning with a paddy winnow on the end of a long light pole, the inside of which is plastered over with jak milk, with which he brushes the top of the paddy to catch the insect pest named goyan messa: were the villagers to neglect the abovenamed pest they would get no crop at all, for the little midge-like insect would destroy the whole crop in a week. When the paddy has been cut it is usually thrashed by the men who fix a horizontal pole to hold on to whilst they crush the grain from the straw with their feet: why buffaloes are not used as in other districts I don't know, the percentage of light is about $\frac{1}{4}$ in each bushel which is winnowed out in the field if the weather is fine before removing it to the houses. The paddy before being pounded out by the women is again winnowed and found to contain about 4 measures to the bushel of light. The outturn of rice from a bushel of paddy is usually half if it has been boiled and dried to toughen the grain and burst the husk to making it easier for the women and prevent wastage, if green or *patcharisi* is required, which is not boiled and contains much more starchy matter and is usually made into flour for hoppers and sweet cakes, the outturn is less than half as there is much more waste. The price paid for paddy in Sabaragamuwa when thoroughly well winnowed is from R1 to R1.50 per bushel according to the distance from the cart road, or large town, and the price of village rice from 8c to 12c. The price paid for converting a bushel of paddy into rice is also from 8c to 12c, but it is usually paid in kind by giving $1\frac{1}{2}$ to 2 measures of rice and the broken leavings. Village rice is much more satisfying than Coast, but it does not boil out nearly so much, and is therefore considered less economical than Coast rice. When very white village rice is required it is pounded with straw, and you would not know it from the best Coast table rice. There is nearly as much hill paddy grown in Sabaragamuwa as wet—the wet climate being very suitable for hill paddy, but it is

not considered so nourishing, and is in my opinion less palatable than the water-grown grain."

From the *Agricultural Journal* published by the Department of Agriculture of Cape Colony (for copies of which we are indebted to the Director of Public Instruction) we find that the scope of work taken in by the Agricultural Department is of an extensive character, embracing not merely crop cultivation, but Forestry, Veterinary, Entomology and Dairy Farming. The Editor of the Journal is the Secretary for Agriculture, Mr. A. Fischer, and being a Government-aided publication, the paper is supplied free to every farmer who is a member of an Agricultural Society or Farmer's Association. The Journal consists of eight pages, and is issued fortnightly. Vine, Hop, and Fruit Culture seem to be among the most important industries, while horse, sheep, and cattle-breeding is evidently much attended to. The climate of the Cape appears to be peculiarly adapted both to temperate and tropical cultivation, and crops and fruit of the East and West seem to thrive side by side with equal luxuriance. The existence of a Colonial Veterinary Surgeon and his assistant as well as the enforcement of regulations in the matter of cattle disease prove that the Government is fully alive to the importance of Veterinary superintendence.

A PETRIFIED FOREST.—One of the wonders of the American continent is Calcedony Park, Apache County, Arizona Territory. It is so named on account of the trees which ages ago fell, and are lying in indiscriminate confusion, having become silicified into agate and jasper, the change being probably effected by heated volcanic waters. On a recent visit some of the trees were found to measure over 100 feet in length. In the agatised condition they are surpassingly beautiful, every conceivable colour and shade being represented, red, yellow, and green, interspersed with white, black, and grey, and by transparent spaces of brilliant quartz crystals. The park is Government property, and its contents are strictly protected.

We have to acknowledge with thanks the receipt of the "St. Thomas's College Magazine," "Onward and Upward," and the "Richmond College Magazine."

It is computed that there are about 600 tons of cotton seed cake consumed daily in Britain, and its use is daily increasing. The oil, which is considered a valuable food oil, is now used in large quantities in the manufacture of lard and butterine, besides being used for the sardine industry. The price of seed which is tolerably free of lint is said to be from £6 to £7 per ton, while the woody seed fetch from £4 to £5. This seed is manufactured into cake which is selling at from £5 to £5 10s. per ton, while the oil fetching from £20 to £23 per ton.

From the report of the Council on Agricultural Education, Australia, the Dookie Agricultural College Farm is doing excellent work. All the branches of an exhaustive course of agricultural science are being taught in a most thorough manner, and the value of the institution is being fully recognised by the Government of that colony. The principal of the Dookie College is Mr. T. L. Thompson. Mr. Thompson has been conducting experiments to test the advisability of thick *versus* thin sowing. With 2 bushels of seed sown per acre, the produce was only 10 bushels; where 1½ bushels were used, the produce rose to 14½; 1 bushel of seed gave 18½ bushels per acre; while 1 acre which received only ½ bushel of seed, yielded 21 bushels. From another carefully-conducted experiments, Mr. Thompson found that when the seed was covered to the depth of 3 inches the produce was immensely greater than when only covered to the depth of 1 or 2 inches, or even when covered to a depth of inches.

"Coconut cake" is selling in London in bags or ground into meal at £7 10s per ton. It is described

as pure, soft, rich, sweet cake, eaten readily by stock. The guaranteed analysis is as follows:—15 per cent oil, 19 per cent flesh-formers, 40 per cent fat-formers.

"Observations on Some Injurious Insects of South Africa" is the title of a little work published by Miss E. A. Ormerod.

A new cotton-seed company has been lately started in Dundee. The process of removal of lint from the seed consists essentially in using dilute sulphuric acid to break up or disintegrate the cotton adhering to the seed. The process is not particularly novel, as strong sulphuric acid has been used for the purpose, and the only difference between the new process and the old is the relative strength of the acid used. The two great difficulties which the company, if it be successfully floated, will have to face are (1) the presence in the manufactured article of a minute quantity of free sulphuric acid, which is detrimental to animal health, and (2) the cure with which the patent, for which a large sum of money is to be paid, can be evaded by using acid of a different degree of strength.

An investigation made by a board of United States army officers for the purpose of deciding upon the best methods of shoeing, has resulted in the issuing of the following order which all owners of horses should read as it contains points worth knowing:— In preparing the horse's foot for the shoe, do not touch with the knife the frog, sole, or bars. In removing surplus growth of that part of the foot which is the "seat of the shoe," use the cutting pincher and rasp, and not the knife. The shoeing knife may be used, if necessary, in fitting the toe clip. "Opening the heels" or making a cut into the angle of the wall at the heel must not be allowed. The rasp may be used on this part of the foot when necessary, and the same applies to the pegs. No cutting with a knife is permitted: the rasp alone when necessary. "Flat-footed horses should be treated as the necessity of each case may require. In forging the shoe to fit the foot, be careful that the shoe is fitted to and follows the circumference of the foot clear round to the heels; the heels of the shoe should not be extended back straight and outside of the wall at the heels of the horse's foot, as is frequently done. Care must be used that the shoe is not fitted too small, the outside surface of the walls being then rasped down to make the foot short to suit the shoe, as often happens. Heat may be used in preparing and shaping the shoe, but the hot shoe must not be applied to the horse's foot under any circumstances. Make the upper or foot surface of the shoe perfectly flat, so as to give a level bearing. A shoe with a concave ground surface should be used.

SCHOOL NEWS.

The annual examination began on the 11th November and lasted on to the 19th.

The students were enabled, through the kindness of the Hon. W. W. Mitchell, to visit the Spinning and Weaving Company's Mills at Wellewatta, where Mr. Atherton, the Manager, obligingly explained the use of the Machinery fitted up in the building.

The Sanitary Officer also kindly arranged that the Veterinary Class should visit the Slaughter House at Dematagoda, where Mr. Brandon, the Slaughterhouse-keeper, was good enough to conduct the students over the premises.

The School Museum where we are endeavouring to collect Agricultural, Botanical, Geological and Entomological specimens, is yet of a very unassuming character. We had an interesting addition made lately to our geological section in the form of a water-worn mass of granite which, having been imbedded in a calcareous deposit, is thickly interspersed with the exuvia of Tubicolous annelides, evidently serpulae. We shall feel extremely grateful to those who will send us any specimens for the Museum.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. IX.]

COLOMBO, JANUARY 1ST, 1890.

[No. 7.

RAGS AS A MANURE FOR TEA.

SOME years back there was an animated discussion in the public press relative to the positive assertions made that piles of old rags had been known to spontaneously generate rats. The *gobemouche*^s who expressed belief—as undoubtedly many did—in this most ridiculous statement went some of them so far as to declare that they had seen those rodents in their transition state of half-rat, half-rag. Such nonsense soon died, as it deserved to do, a natural death. However, we are now told on high authority that these same foul rags may form an important constituent in manure for our tea plants. Mr. Hughes, the well-known agricultural chemist^t has told our London correspondent (see page 451) that such refuse contains in a high degree the elements most fitted to restore to the soil in which the tea and other kindred shrubs are grown, the fertility of which a long course of exhaustion has deprived it. Mr. Hughes adds the important fact that, when travelling in the south of France and in Italy, he observed that waste rags were most extensively used as manure for the olive trees so largely cultivated in those countries.

His observations of this practice appear to have led Mr. Hughes to the conclusion that the main value of the application of such a fertilizing agent arises out of its very gradually produced effect. He tells us that for all shrubs the application of a "forcing" manure is injudicious. For an application to be thoroughly efficient, according to him, all plants of the family to which tea, the olive, &c. belong, require slow feeding, and this result is thoroughly attained, judging from the experience of the olive growers of the countries mentioned, by the gradual decay of the rag and the corresponding degree in which it yields up its nitrogenous properties. We learn by our London Letter by last mail, that, so convinced is Mr. Hughes of the utility of this agent for manuring tea plants, that he has recommended Mr. Rutherford, who had been in communication with him on the subject of a fertilizer for his well-known estate of Mariawatte, to send out a trial shipment of manure largely com-

posed of a material kindred in character and properties to the waste rags so largely used by the cultivators of the olive. It appears that this material is derived from waste woollen rags, which are reduced by the agency of steam to the condition of a fine dust. Not only is woollen cloth dressed with oil, but it is specially absorbent of all greasy matter. Mr. Hughes says that the use of rags, as he had observed it abroad, was attended with many inconveniences due to the foulness of the smell arising from the accumulation of rotting rags, as well as with no small amount of insanitary danger. He would therefore on no account recommend the adoption by ourselves of the use of the raw material as he had seen it employed; but the preparation above referred to, while rendering the raw basis perfectly innocuous, maintains and preserves in a high degree the nitrogenous ingredient of it, and it appears that in this form the new manufacture already enters largely into the composition of many manures prepared at home.

Mr. Hughes has recommended for application to the tea plant an admixture with this material of a considerable quantity of superphosphate with the object of preventing the escape of the volatile ammonia which is in itself so important a fertilizing agent. Thus prepared, he believes the manure may be safely applied to the tea shrubs on our estates, and he predicts great advantage from its employment. At the same time he admits that no manure could be found or applied likely to produce better results than poonac; but the cost of this agent would be likely to prove prohibitive, there would be great temptation to theft of it, and its bulk for carriage would be considerable, while it is doubtful, moreover, whether it could be procured in anything like the quantity which—if free manuring of our tea be resorted to—would be required. Now in Mr. Hughes's opinion the day draws near at which, if the produce of our tea bushes is to be maintained, it will be necessary to adopt such free manuring. Tea, he tells us, is an exhausting crop, and it takes comparatively but a short time for the soil in which it is grown to show signs of exhaustion. While the prices obtained for tea were day by day lowering, it was not possible in Mr. Hughes's view to urge our planters to incur the cost necessary to stave off the evil day to be anticipated. When, however, prices had risen and were expected to show a steadily improving tendency, he thought it desirable to utter a note of warning. In his opinion, if our planters are wise, they will act on this warning without much further delay, and the trial to be made by Mr. Rutherford on what has hitherto been one of the most productive tea estates in the island will

furnish them with an example, from the result to which a most useful lesson may be gained.

We shall watch therefore with much interest the application of this very novel form of manure, feeling confident that Mr. Rutherford, with his usual public spirit, will publish full details of results compared with cost. We are told that the first shipment was to be made almost immediately, and probably the next season's crop upon Mariawatte may furnish some indication to guide our planters generally. We feel quite sure, we may repeat, that Mr. Rutherford will not withhold from his brother planters any information it may lie in his power to afford them; and if what he may have to communicate should be favourable, we may yet expect to see large crops of leaf upon our tea bushes developed from the oily waste of engine rooms, and, possibly, from the cast-off clothing of millions of tea drinkers throughout the world. There is much of affinity between the characteristics of the olive and tea shrubs, and as experience has demonstrated how the former has benefited by the application of this novel fertilizer, there is every reason to hope that tea may reap a similar advantage from it.

Another substance rich in nitrogen is the fish manure from the Malabar Coast, now being locally advertised. Those who are trying it, will also, doubtless, in due time, make known the results.

INDIAN TEA EXPORTS ESTIMATE REDUCED $4\frac{1}{2}$ MILLION LB.

Indian Tea Association, Bengal Chamber of Commerce: Calcutta, 18th November 1889.
To the Editor, "Ceylon Observer."

DEAR SIR,—In their circular of the 26th April last the General Committee gave an estimate of the output of the present Season's Crop of Indian Tea based upon the following figures which they had been able to collect:—

ORIGINAL ESTIMATE OF CROP OF 1889.	
	lb.
Assam	44,953,400
Cachar and Sylhet	31,990,400
Darjeeling, Terai, and Dooars...	20,460,620
Chittagong and Chota-Nagpore	1,536,740
Dehra Dun, Kumaon and Kangra	4,500,000
Private and Native Gardens ...	3,500,000
	106,941,160

From figures which have since been obtained a revised estimate has been prepared based upon actual results to the 30th September, as follows:—

	Manufactured to 30th Sept. 1888.	Manufactured to 30th Sept. 1889.
	lb.	lb.
Assam...	31,068,405	32,022,022
Cachar and Sylhet...	19,628,759	20,197,986
Darjeeling Terai and Dooars	14,922,342	16,152,137
Chittagong and Chota-Nagpore	889,200	854,210
	66,508,706	69,226,355

REVISED ESTIMATE OF CROP OF 1889.

	lb.
Assam	42,080,564
Cachar and Sylhet	29,750,054
Darjeeling, Terai, and Dooars...	20,497,857
Chittagong and Chota-Nagpore	1,378,920
Dehra Dun, Kumaon and Kangra	4,500,000
Private and Native Gardens ...	4,500,000
	102,657,395

The exports to Australia, America and other places for the past season amounted to 4,278,809 lb., and if this quantity together with the requirements of Northern

India now calculated at 500,000 lb., be deducted from the Revised Estimate there will remain about 98 million lb. for shipment to Great Britain during the season of 1889-90 against 92½ million lb. shipped therein 1888-89.—Yours faithfully,

S. E. J. CLARKE, Secretary.

PLANTING IN DELI.

Advices from Holland in the *Deli Courant* bring word of the departure of a party of Germans, under the leadership of an ex-lieutenant, to that Settlement. They aim at gaining experience in tobacco cultivation and turning it to account in German New Guinea.

At a meeting held in Medan the other day, the shareholders of the Deli Steam Navigation Company decided upon raising 100,000 guilders through debentures bearing 5 per cent interest. The Company is said to be going ahead, and to have made arrangements for keeping up regular communication between Deli and Penang.

In Assahan, the high prices ruling for locally grown tobacco have resulted in the district being overrun by land selectors. The consequent rise in the value of real estate has proved very satisfactory to the Sultan of the country. Fresh applicants are said to have hardly any chance, owing to the pick of the land having already been secured by planters earlier in the field. In consequence of the growing prosperity of the country, Tanjong Balei, the capital, has greatly improved in extent and appearance, the building of new houses being actively proceeded with. The only drawback to its attracting more population lies in a large portion of the town being below high water-mark.

The Arendsburg Company, which works large estates in Deli, has it is said, acquired land in Borneo as well.

On the 1st November, the Deli Company took over the adjoining estates of the Langkat Association thereby bringing two large stretches of cultivated land into one.

Throughout Deli in October, as usual at that time of year, rain showers fell almost daily, the roads being in consequence rendered almost impassable in all directions. This year's tobacco crop, however, has all been gathered, and, in all the estates, sorting operations have been actively carried on. Plantation roads and drains have been vigorously taken in hand preparatory to planting the next crop. Ploughs and hoes have been set to work in the lalang fields which have to be put under tobacco. Direct coolie immigration from China continues, no less than 193 arriving on the 2nd instant.—*Straits Times*, Nov. 19th.

PATENT TEA CHESTS; TEA TASTING AND MR. JOHN HUGHES; MANURING OF TEA ESTATES.

Next Monday (Nov. 18) has been fixed for a trial before those interested of the machinery for making the Stanley-Wrightson tea chests, but as some unimportant hitches have occurred in its working on its first erection, it is possible that, if they are not overcome before the day decided upon, a postponement of the trial will take place. If present arrangements, however, are maintained, it will be possible for me to give you in my next letter some details of the proposed system of manufacture of the new tea chests. The straw boards supplied by makers in Holland have been so untruly shaped, that much difficulty has been experienced with them; but this mistake will doubtless be rectified in the case of the next supply to be indented for.

When making the suggestion in my last letter that possibly distillation of the water used for tea tasting might tend to equalize results as recorded

by experts, a good deal of diffidence was felt by me owing to my want of acquaintance with such subjects, but Mr. Hughes has this week confirmed the view expressed. He has told me that distillation would bring all waters pretty much to a parity in qualification, with the exception, however, that the distilled water produced from that containing the larger proportion of solids originally would be more "lively," more full of the carbonic acid gas which would be evolved from the impurities during distillation, and which could not be got rid of. He told me of his surprise at reading in the last *Ceylon Observer* of the result to analyses of your Colombo water only showing 1.5 grain of deposit per gallon. Now the purest water in the United Kingdom is that of Glasgow, and this has 4 grains per gallon of such deposit. London water has as much as from 25 to 30 grains, and Mr. Hughes considers the report on the Colombo water to be quite exceptional in the results it records. Not that he thinks you are altogether to be congratulated upon this exceeding purity. All such very soft waters, he says, are deficient in lime-salts, and the absence of these in potable waters is very injurious to infants and growing children. So much so is this the case, that Glasgow, with its lowest record of solids in its water, is notorious for rickety and badly developed children. It is desirable in the case of such waters to add constituents to it when given to infants and young children. But this allusion is somewhat foreign to the immediate subject of this paragraph. Mr. Hughes thinks, however, that the suggestion timidly made by me would, if carefully acted upon both in Ceylon and at home, do much to remove the diverseness complained of between the two sets of reports. But he is not inclined to think it wise to expect an absolute coincidence as regards these even were such precautions fully taken; because he holds that great changes may not improbably take place during the journey of the tea homewards. If, he says, it should happen that there remain the least dampness in the tea, the great heat of the holds in the Red Sea—in his own experience fully 90 degrees, and I should personally put it at a far higher range, would be certain to induce a further amount of fermentation, and if this had been carried to the proper standard during curing operations to insure good tea, the second fermentation would go beyond that standard and the tea would be deteriorated. Therefore he thinks that under any condition it would be unwise for merchants here to buy teas on reports made by tasters in Ceylon.

During the course of our conversation on the above topic, Mr. Hughes informed me that he had lately been consulted by Mr. Rutherford about manure to be applied on that gentleman's well-known estate of Mariawatte, and that a consignment of a fertilizer he had recommended was to be shipped within the next few days. Mr. Hughes holds that now that the price of tea has so much improved, you should take early steps towards neutralizing the exhausting effect of growing tea on your soils. He had been reluctant to urge this while prices remained depressed, as he saw the uselessness of his doing so. On my inquiring the nature of the manure he had recommended, he said:—"When travelling last year in the South of France and Italy, I was struck by the great use made of old rags for manuring the olive trees. These rags were collected all the country round, and the stench from them was beastly and must have been unhealthy. But there could be no doubt of their great effect in promoting the vigour of the olive plants. Old rags contain a large amount of nitrogen. This, if applied suddenly, is injurious to all shrubs, it is too forcing. You

want to apply it gradually, and the rags do this during the long process of rotting. Mr. T. H. Woodman, of 75 Quintin Road, Blackheath, subjects woollen rags to the action of steam and produces a fine powder which is perfectly innocuous, but it retains the full quantity of nitrogen contained in the rags. I have recommended that this should be mixed with a proportion of superphosphates, which will have the effect of keeping in the volatile ammonia, and I believe that the admixture is likely to be productive of good results, for Ceylon soils are very deficient in natural phosphates, while nitrogen is the best possible stimulant for tea and other growths of the kind. The new powder is largely made use of in the composition of mixed manures." Possibly, therefore, some day Ceylon will be giving us tea grown from our own cast-off garments!

TRIAL AND INSPECTION OF STANLEY-WRIGHTSON TEA CHESTS.

London, Nov. 22nd.

On Monday last (Nov. 18th)—as was stated in my last letter would probably be the case—the public inspection and trial of the machinery erected for the making of the Stanley-Wrightson tea chests was held. At 10.45 on that morning, between twenty and thirty gentlemen left Fenchurch St. for Grays in a specially provided saloon carriage and descended—the train being stopped for that purpose—at the grounds of the Tunnel Cement Works within which the new buildings have been erected by the Syndicate. Among these visitors we observed Messrs. Rutherford, Alexander Ross, J. F. Churchill, J. Capper, W. M. Leake, Channing Esdaile, and one or two other gentlemen connected with Ceylon. It had been mentioned to me that out of its nominal capital of £2,500, the Syndicate had expended but little over £1,200 in the provision of buildings and machinery, so my expectations were not raised about beholding anything very striking in the way of exceptional novelty in the machinery. The Syndicate has done wisely in commencing what is but a tentative experiment by restricting its present outlay as far as might be possible, and by its adaptation of existing forms of machines as far as practicable to the speciality of its manufacture. For fully two hours, however, the visitors were interested in watching the operation of making a new tea box from the first handling of sheets of straw-board as received from Holland, to the final turning out of the finished article. There are two branches of operation entailed in the manufacture, one consisting of the manipulation and treatment of the boards, the other being connected with the cutting, drilling and bending of the iron strips and hoops by which those boards are put together. Taking the former operation first in order, we saw the boards which are received from the Dutch factory of the exact sizes required, passed through a sizing machine which by means of felt-covered rollers spreads the size evenly upon their surfaces passes them on wires through a long chest heated by steam pipes, and delivers them ready for receiving the varnish at the further end of it—the varnish is applied by hand only to that face of the boards which is to be external, this being dried in an iron cup-board furnished with shelves of corrugated iron. A machine having a table through the surface of which the heads of several small circular saws appear, cuts off the strips of straw boards which are rivetted on to the tops and bottom panels to give the thickness required for holding the screws. This list comprises all the methods of treatment to which what may be termed the "raw material" of the boxes is subjected. A goodly array of cutters, pinchers and

presses, convert the strips of hoop iron into the desired lengths, make all screw and rivet holes, and give the required angle to the corner bindings and the V shape to those which protect the edges of the straw-boards. The putting together of these several components of the boxes is at present done exclusively by hand, every provision being made, that all the rivetting &c. should be finished off with the required degree of uniformity to insure ready and facile putting together on the estates. There is much of this part of the labour, the cost of which may be ultimately greatly reduced by the employment of specially adapted machinery; but the Syndicate has done wisely not to incur the expense of this until a trade has been secured. The buildings are of ample size and well adapted to the processes to be carried on in them, while a neat little engine of some six to eight horse-power supplies all the motive force likely to be demanded for some time yet to come. It is computed that the finished box can be made for about 2s 6d, the producing power of the present machinery being estimated at 1,200 boxes per week. We have been told that the average cost of a wooden box (half-chest, I think) on a Ceylon estate is about 2s 3d; so that at first sight it would appear as if competition must result adversely to the new design. But other conditions operate to redress—and more than redress—this inequality in cost, for the neatly finished exterior of the new box enables 17 boxes to be shipped to the ton of measurement as compared with only 12 of those of the kind at present in use. We witnessed in addition to the foregoing operations, that of sewing by machine the edges of the lining papers supplied with the chests, but it appeared to me that this somewhat costly process might well be superseded by some method of gumming and pressing.

The inventors, who were present, declared their wish to receive suggestions for any possible improvement, and many of these were made, the adoption of some of which will be likely, it was admitted, to very materially reduce the cost of production and facilitate the work of putting the boxes together on the estates. I must not, however, occupy more of my space in this letter by discussing these, and I must conclude my remarks respecting a very interesting day by telling you that, with a thoughtful courtesy, the Syndicate had provided carriages to take their guests some 1½ mile or so to the Tilbury Hotel, where a very appreciated lunch was also provided for them, the whole party returning to town by about 3.30 p.m.

Although anxious not to devote too much space to the topic above treated of, it appears desirable to refer to it further in connection with the possible initiation it may produce of a new local industry for Ceylon. Judging from statements made as to the amount of support promised by China, Indian, and Ceylon tea planters and shippers, it appears to be probable that a large demand may arise for these chests, such as would for economic reasons render it desirable that the straw-board should be manufactured locally in the East, where its raw basis is so readily obtainable—Ceylon, with its readily adaptable water-power and its large acreage of growth of paddy, mana and citronella grasses, is deemed to be specially adapted for such manufacture, and it is under present consideration, we hear, to establish a factory with this object somewhere in the neighbourhood of Galle. Dr. Trimen has expressed the view, we learn, that both mana and citronella grass are better adapted, owing to their containing much less silica than does straw, to form the basis of these boards, and we can therefore foresee how good a chance there is, if there should be large use of these chests, that a new and

very valuable industry may be established among you. Mr. Stanley—one of the patentees—expressed to me the great obligation he had been under to the *Tropical Agriculturist* for the extended and most useful information it had supplied to him as to the methods of tea-packing &c. which he had to consider during the process of his designing. He said he had been quite at a loss for means of obtaining such information until he lighted upon the file of the *T. A.* kept at the London Patent Office.

SCOTTISH TRUST AND LOAN COMPANY OF CEYLON, LIMITED.

The Directors present their Twelfth Report, being for year to 31st August 1889.

ESTATES IN COMPANY'S POSSESSION.—The cultivation of these continues to receive careful attention, and the Directors have pleasure in reporting that the products from several of the estates have commanded some of the highest prices in the London Market. The Tea Factory at Alnwick has been completed, and is in active operation, while the returns from that at Annfield show a satisfactory profit for the year. The estimate of made Tea from the Company's Estate for the current year is 245,000 lb., as against 188,000 lb. last year. The cost during the year of tea cultivation and extension, other than that connected with the erection of factories, has been charged against Revenue.

PRODUCE IN HAND.—Owing to the delays consequent on the strikes at the London Docks, there was considerably more Produce in hand and *in transitu* at the close of the accounts, than at the corresponding period last year. The Valuations have been carefully made.

MORTGAGES IN CEYLON HELD BY THE COMPANY.—These have again been reduced, and the interest has been well met, the greater part of the arrears having been recovered since the close of the accounts.

DEBENTURE DEBT.—The Directors have maintained their policy of steadily reducing both the principal and the rate of interest as occasion offered.

The Balance at the Credit of Profit and Loss Account is £5,342 3s 6d and the Directors propose—

to write off one-fifth of the cost	
of the Tea Factories, ...	£614 2s 6d
to carry to Reserve Fund, ...	500 0s 0d
to pay a Dividend of 5 per cent.,	
free of Income Tax, ...	2,250 0s 0d
	£3,364 2s 6d

Leaving £1,978 1s 0d
to be carried forward to next account.

BALANCE-SHEET as at 31st Aug. 1889.

THE NEW DEPARTURE IN CONNECTION
WITH THE PEARL FISHERIES
OF CEYLON.

In connection with probably all the pearl fisheries which in modern times have taken place in Ceylon, speculators have brought small lots of oysters in swift sailing boats for sale in the capital and the chief towns of the colony. But during the period of some thousands of years, during which the banks off the north-west coast of Ceylon have yielded their treasures, the idea seems never to have suggested itself until now, of dissociating the processes of cleaning and searching the shells from the scene of diving and raising the oysters. Indeed, until the era of steam, any such attempt would have been impracticable. We cannot doubt that sanitary considerations and a desire to save the colony from a repetition of the lamentable casualties which marked and prematurely closed the fishery of 1888, owing to the outbreak of epidemic cholera, have operated strongly to induce a trial of the experiment of bringing the oysters about a hundred miles from the banks which form their abodes, for sale and treatment. While steam renders this possible, sanitary science, now so greatly advanced, steps in with appliances and precautions, calculated to render unnecessary the horribly disgusting and dangerous process of putrefaction, the abominable smells, the armies of crawling maggots and the plague clouds of flies which have been ever the accompaniments of fisheries conducted after the orthodox fashion on the dreary coast of Arippu and Silavatturai, off which lie the Modaragam, Cheval and

the other series of chief "pars" or banks, which are the favourite feeding and breeding grounds of the pearl oysters. The application of the incinerating process to the flesh and other waste matter of the shells may lead to the loss of a few pearls, but such a consideration is of no account in comparison with the benefits conferred on those connected with the fishery and on the community at large. Capitalists who wish to speculate in pearl shells can now live comfortably in Colombo instead of being condemned to lodge in palm leaf huts, and to inhale odours, compared with which the "two and seventy stinks" of Cologne, immortalized by Coleridge, are as nothing. Speculators with limited means, too, inhabiting the capital or its neighbourhood, will have facilities for trying their chances, and we shall be surprised if increased competition, thus rendered possible, does not far more than repay the cost of transit of the bivalves. Indeed we believe it quite possible that the results, pecuniary as well as sanitary, of the experiment which Captain Donnan is employed to carry out may entirely revolutionize the order of our pearl fisheries, so that the pearl bank region (so dreary and barren since Tamil raids led to the destruction of the ancient irrigation works) will be the scene merely of the diving and raising operations necessary for the harvesting of the shells, the precious fruits of "the harvest of the sea" being realized, as in the present case, near Colombo. If the experiment initiated in connection with the small fishery off the Karaitivu bank proves a success, we cannot doubt that the remainder of the oysters on the Dutch Bay bank will be dealt with after the same fashion. There can be no doubt that our neighbours in Southern India will watch with almost as much interest as ourselves in Ceylon the results, economical, sanitary and general, of an experiment so curious and interesting. The only sufferers by the success of the new departure will be the wretched inhabitants of the Mannar district, who will be deprived of the profitable employment to themselves and their buffaloes, in connection with the palisades and buildings which hitherto have had, with every recurring fishery, to be erected at Silavatturai. But the people of Mannar ought to be compensated by irrigation works to make their rich soil laugh with fruitfulness. Of course accommodation and supplies for the divers will still be required.

REGULATING TEA SALES AND REFRINGING:
CUSTOMS PRACTICES.

(From the Home and Colonial Mail.)

Our correspondent, Mr. G. Seton, calls attention to the important subject of the necessity for controlling the supplies of Indian and Ceylon tea placed on the London market. Although the depression in prices occasioned by the excessive supplies offered for sale in Mincing Lane is deplored, and the feeling in tea circles is that something ought to be done, nothing is done. Few people other than speculators wish to cause a famine or a "corner" in tea, nor is it generally desired to depart from rectitude to the extent of keeping back tea to the injury of the consumer. The course suggested is that the market should be controlled with some regard to the eternal fitness of things, and that instead of throwing tea upon the market in the present hap-hazard way, some method should be introduced in place of the ruinous course now pursued. "Where there's a will there's a way," and if tea companies and tea agents will combine with the object of preventing the needless sacrifice of the growers' interest, there need not be any difficulty in bringing about a change for the better.

Tea planters do not brave the vicissitudes of climate and exile from home for the inferior pleasure of putting money into the pockets of the retailer, nor of illustrating the laws of political economy. Nor is it the leading idea of investors in tea shares that tea should be "laid down" in London at prices which mean ruin to the garden. If the tea drinker reaped the benefit of this "sweet plethora" of the leaf there would perhaps be some small satisfaction derivable from the fact, although even then the planter might think the game was not worth the candle. But there is not this consolation. The retailer and those who supply him are enabled to revel in the situation, to turn up their business-like noses at the quality of tea offered, and to commune with themselves and their friends upon the folly which permits it.

With the probability of a short crop, the tea market is, at the present time, in a miserable condition as regards prices. The deliveries are excellent, but this goes for naught, because of the rush to be first in the field—or in the "Lane"—with tea. There are times when individual interests must give way to the general welfare. This is a case in point. Let the tea companies and tea agents meet in council, and make some effort to stop the flux of tea, and the consequent loss to the grower it involves.

We print a letter from Mr. D. F. Shillington, who calls attention to an episode in the history of tea upon its arrival at the London warehouses which tells its own tale. The planter "frets his soul" in the endeavour to send home tea in good condition, and the Custom House officials, who only come round to the warehouses "when there is something worth while to do," can upset all his plans, and cause his tea to be exposed to the London fog for hours or days. We feel sure the zealous secretary of the Indian Tea Districts Association will communicate with the magnate of the Customs on the important subject. It might be pointed out that fog does not conduce to aroma or flavour in tea, and that the proceeding of the Custom House subordinates in this matter are likely to cause growers in India and Ceylon to "say a swear."

But the injury the planter suffers in the matter is perhaps less than that inflicted on the dealer and the grocer who purchase tea from samples. They really taste and smell one tea, while they are buying another, supposed to be like sample, but which is, owing to the course of bad atmosphere to which it has been subjected, of an inferior quality.

"H. C.," who refers to himself as the "boycotted tea planter," seems to have opened the campaign against Mincing Lane with a light heart. The back page of last Sunday's edition of the *New York Herald* contained the story of "H. C.'s" alleged wrongs in six short chapters, and it also conveyed the intimation that "H. C." was willing to play the part of two business gentlemen rolled into one—i. e., he would abolish the broker and the dealer, acting himself as the only intermediary between the planter and the grocer. He says he has already received the support of a number of grocers, and he infers that he is going to do a roaring trade.—*H. and C. Mail.*

CONTROLLING THE QUANTITY OF TEA PLACED ON THE MARKET.

To the Editor of the "Home and Colonial Mail."

SIR,—In March last, and again as far back as December, 1888, I addressed a letter you on the above subject. I regret to find, however, that nothing has ever yet been done, on the self-help principle, on the line then indicated.

Without, however, again going into any detail, I venture once more to urge on your readers the importance of acting together in this matter for the common good and would refer them to my letter which appeared in your issue of 15th March last. Urgent as it was then, and strong as was the position at that time, it is now very much more urgent, while the position is much stronger. We have—

1. A large falling off in China supplies.
2. The quantity of Ceylon tea considerably short of expectations.

3. A distinctly short crop from India.

While on the other hand we have—

4. An enormously large consumption of Indian teas steadily progressing.

The peculiar feature of the present Indian season is that, owing to unfavourable conditions in the early part of it, the great bulk of the crop is coming upon the market almost all at one time, which, of course intensifies the difficulty of the position during the months of November to February; but, despite of this, the crop is distinctly short, and actually less than our current year's requirements. We find, however, that although the crop, to land here, cannot exceed 100 millions, we are actually selling just now at the rate (if continued through the year) of 200 millions, or practically twice as much as is necessary were the supply distributed over the whole year. This speaks for itself.

I am aware that most of the large importers will retort that they have on different occasions held back their teas, and that to their own detriment; but I contend that no united action has ever been taken, and without some united effort of this kind any individual attempt to stem the current will undoubtedly fail, those who take action being themselves probably the chief sufferers.

If only, say, 40 to 45 per cent. of sellers were agreeable to combine with a view, not to taking any action which would unduly raise prices, but merely to control excessive supplies rushed upon the market, we should, instead of having a dropping or declining market,—unfavourable alike to buyer and seller—have a steady and possibly even a slightly advancing market from now on to the end of the season.

As I write I learn that several of the large importers are seriously considering as to "holding off the market;" unless, however, there is combination these parties will probably only themselves suffer, to the advantage of others.—Believe me, yours faithfully,
GEORGE SETON.

HOW THE TEA TRADE SUFFERS.

To the Editor of the "Home and Colonial Mail."

Sir,—In your last issue you favoured your readers with an extract from the *Grocer*, under the heading of "Here is a wail from the 'Lane.'" It may interest them to have further particulars of how the tea business it at present conducted in some of the large dock warehouses. I had occasion to go into one of them last Friday, and on going up to the tea floors was astonished to see no less than twenty-three breaks of Indian tea all in bulks on the floor.

I made some enquiry and learnt that in the usual course the packages would be refilled in two days from being turned out. I then asked why each break was not turned out, bulked, and refilled before commencing the next one, and the answer was that as each chest had to be separately tared they had to wait for the Customs officer, who only came round for the purpose when there was something worth while to do.

Now, it seems to me that all the care of planters in fine plucking and careful firing is to a large extent thrown away if after it the tea is to lie open for two days on the floor of a London warehouse with all the windows and doors open in damp and foggy November. The importer gets a few chests put on show from which the trade draw samples, but the bulk absorbs moisture in proportion to its dryness and quality, and a secondary fermentation is started, which destroys the flavour within the prompt. Who is to rectify this state of things? The dealers know nothing of it; the selling brokers do, but whilst they are well aware of the damage to the tea they seem to be powerless to alter it. Anyhow, the thing is wrong and it is in the hope that drawing attention to it in your paper may induce some one to stir in the matter that induces me to trouble you with these lines. Should not the Indian Tea Districts Association represent the matter to the Commissioners of Customs, in order that the delay in refilling might not rest with the Customs officer?—I am, &c.,

D. F. SHILLINGTON.

GREAT IMPROVEMENT IN FIBRE CLEANING MACHINES AND APPLIANCES.

SISAL OR ALOE HEMP: A NEW INDUSTRY READY TO BE ESTABLISHED IN CEYLON: WHO WILL BEGIN?—COLOMBO MERCHANTS URGED TO TAKE THE INITIATIVE.

The great difficulty in regard to most fibrous plants is that of getting rid of the extraneous matter in leaves and stems, cheaply, expeditiously and without injury to the colour and strength of the fibre. The lengthened retting process applied to flax, in temperate climates, is ruinous in a tropical climate, and chemical applications are expensive and likely to act injuriously on the fibre. In the case of rhea or ramie, which yields the China grass of commerce, the difficulties of preparation are intensified by the large proportion of gum which binds the woody matter and fibre (one of the finest in the world) together. Our readers are aware that the Indian Government offered a prize of Rs50,000 for a machine which would successfully overcome the difficulties, but the perfect machine has not yet been produced. Trials of machines at Paris in 1888 did not give satisfactory results, and we have waited with special anxiety for Mr. D. Morris's report on the competition of machines in the Great Paris Exhibition of this year. It has reached us in the *Kew Bulletin* for November, and shows an immense and most encouraging advance, so that evidently we are within a near distance of a simple, cheap and effective fibre-cleaning machine. For instance, green stems being dealt with, 287 lb. of perfectly clean "ribbons" per diem were obtained by an improved machine against only 120 lb. from dry stems in 1888. A larger machine gave results in proportion, equal to half a ton per diem of ribbons, not quite clean, but requiring some after-treatment of washing to remove woody matter and gum.

The report in full will appear later on so that readers can judge for themselves as to various machines and their performances; but we must draw special attention to one appliance which is not a machine, but merely a zinc tank which, where labour is cheap, can, with a table to receive the treated stems, be carried about the fields where the Rhea is growing. The stems are placed in water in this tank, which is heated by the waste of the stems themselves, and after steeping for a short period, until the gum and woody parts are loosened, the stems are taken out and cleaned by hand. We believe labour is cheap enough to make the process a success here in Ceylon, and we do not see why it should not be applied to aloes, *Calotropis gigantea* and many other fibrous plants. Besides giving Mr. Morris's elaborate report in full further on we here quote the description of the simple and wonderfully effective tank and boiling water process:—

FLÉURY-MORICEAU PROCESS.

Only one process was shown. This was singularly simple, and consisted of steeping the fresh (or dry) stems for a short period in boiling water and removing the ribbons by hand. An open galvanised tank about 6 feet long, 2 feet wide, and about 4 feet deep, filled with water, was raised on bricks (or stones) about 18 inches from the ground over an open fire. When the water had reached boiling point a crate containing 50 to 100 fresh stems was lowered into it and (depending on their age and character) left in it for 5 or 15 minutes. At the end of that time the crate was lifted out, the stems left to drain while another lot was put in. The stems already steeped were then taken up by a couple of workmen and quickly and effectually cleaned by hand. The action of the boiling water had apparently thoroughly loosened the attachment of the cortex to the wood, and ribbons were produced perfectly clean and regular, and apparently without any loss of fibre.

This method was tested in the first trials only. The operation began by placing 18 kilos. of fresh stems in boiling water and allowing them to remain there for 10 minutes. In 36 minutes (or in 46 minutes including the time occupied in immersing the stems) the workmen, apparently not specially trained in the work, produced 5,600 kilos. of excellent ribbons. This would be at the rate of 73 kilos. of wet ribbons per day of 10 hours; or of 161 pounds (avoir.) of dry ribbons for the same period.

This process, it will be noticed, is of the simplest possible description. The only apparatus necessary is a tank. This tank could easily be moved from place to place in the field, and the wood of the stems after the ribbons are removed would probably furnish most of the fuel necessary. The process can, however, only be utilised in a few special countries where labour is very cheap.

M. Crozat states that ribbons produced by this process can be dried, baled, and delivered ready for shipment at a cost not exceeding 8 to 10 centimes per kilo. (about 85 shillings per ton.) In no kind it could be done for even less than this.

It will be noticed that the Fléury-Moriceau process follows somewhat on similar lines to that of the Favier process of 1882. In this latter the stems were steamed for some time in a close fitting cylinder. The former is, however, much simpler, and requires absolutely no skilled labour, nor any plant except an open tank, large or small, according to the circumstances of the grower.

The inventors of the Fléury-Moriceau process are evidently of opinion that wherever cheap labour is obtainable it is in every way preferable, in the production of Ramie ribbons, to the best machine. After all, placing the Ramie stems in boiling water is only a modification of the old retting process practised so long by the Chinese, and by means of which probably the China grass of commerce is still produced. In any case the Fléury-Moriceau process deserves to be carefully considered, and especially in its applicability to the circumstances of India. There the ryots might grow Ramie in small areas, prepare the ribbons and sell them to merchants for export, or to a neighbouring factory or *usine*. The steaming process of M. Favier, designed for use under similar circumstances, failed no doubt on account of the restrictions placed on the use of the patent, and the uncertainty of the demand for ribbons. The Fléury-Moriceau process re-opens the question under circumstances much more favourable, and the subject is one which deserves careful consideration wherever labour is sufficiently abundant to permit of ribbons being produced at a price that will compete with machine-cleaned ribbons.

Will any planter who has plenty of green aloes try the experiment and report the result? Plantain stems might also be tried, although in this case the proportion of fibre (suitable for paper making,) to waste matter is very small. A little soda in the hot water might be useful.

We have been indebted to Sir Bruce Burnside for a good many interesting and valuable extracts with reference to the development of the "Sisal" Fibre industry in the Bahamas of late years under the auspices of Governor Sir Henry Blake. These have duly appeared from time to time in our pages, and recalling the fact that "Sisal" is but another name for "Aloe," and that Mauritius—with fewer advantages than Ceylon—has developed a really important export trade in Aloe Fibre, we do not see why this Colony should lag behind. It behoves one or other of our Colombo merchants to take the initiative: just as the "Kapok" trade has risen, so, and much faster, ought exports of Aloe and other fibres to be set agoing.

Since writing the above, we have received from Mr. F. Cummins, well and favourably remembered in Ceylon, in connection with the P. W. D., copy of a report of the South Florida Fruit Company, in which a passage occurs respecting "Sisal Hemp,"

which is just the fibre of a species of aloe, practically identical with the green aloe (*Fourcroya gigantea*.) which although not indigenous to Ceylon, flourishes exceedingly here, being easily propagated from the multitudes of little plants which actually produce leaves and root bulbs before they drop from the flower stems. The passage regarding the sisal hemp is as follows:—

Dr. Hanson then exhibited to the meeting some specimens of the Fibre known as *Sisal Hemp*. The specimens were of a very strong and silky description. They were subsequently examined by a well-known Rope-Manufacturer and pronounced by him to be of a very superior quality, for which there was a great demand. The plants from which this fibre was extracted grew wild very near the Company's Property; there is a great demand for it in the markets of the United States, where it is used extensively in the manufacture of ropes and cords, having a reputation there coming very little below that of Manilla Hemp.

Hitherto the supply of Sisal Hemp for America as well as almost the whole world has come from Yucatan in Mexico, the planters in which State have exercised practically a monopoly in its production, and have grown very wealthy in consequence. The fibre is there extracted by hand, native labour being very plentiful and cheap. Curiously enough no machine was ever discovered for the extraction of the Fibre until this present year, and no country where Sisal could be grown has ever been able to compete in labour with the cheap producers in Yucatan. A machine has recently been manufactured and planted [patented?—Ed.] in Jacksonville, Florida, which is perfect for the extraction of the *Sisal Fibre* and the specimens produced were extracted by Dr. Hanson himself with one of these Machines. The result of this discovery has been to open up a new Industry which was not contemplated when this Company was first formed. The Sisal plant grows luxuriantly in South Florida, and unlike Tobacco and some other crops, it is not affected by the season; wet or dry, rain or sunshine, it was all the same to the Sisal plant. Dr. Hanson stated that at the lowest computation, the cultivation of Sisal would in two years from the time of planting yield a net profit of at least £40 to the acre, that here were no "ifs or ands" about it, as was the case with Tobacco, because when once the plants were set out they would flourish without being affected by the weather; he gave figures upon which he based this result, and they are set out at the end.

ESTIMATE OF THE YIELD PER ACRE OF THE SISAL HEMP PLANT.

2,240 Plants will be planted to the Acre.

At 2 years, 25 leaves per plant will be cut, weighing upon an average 1½ lb. each.

At 3 years, 40 leaves per plant will be cut, weighing upon an average 2 lb. each, and so for the next 4 years, when the plantation must be renewed.

The leaves will yield 6 per cent of dry Merchantable Fibre

At 2 years:—1 Acre with 2,240 plants will yield 84,000 lb. of green leaves or 5,040 lb. of Fibre

At 3 years, 179,200 lb. of green leaves or 10,952 lb. of Fibre.

Total. 15,992

or on an average of about 8,000 lb. a year.

8,000 lb. of fibre at 8 cents a lb. (a very low price) 640 dollars

Deduct cost of Marketing at 3 cents a lb. 240 dollars

400 ,, or £80

It will therefore be seen that Dr. Hanson's estimate of £10 is well within the mark.

Mr. Cummins writes with reference to the above:—
"In sending you this I wish to draw your attention to what is said of the machine recently invented for extracting the fibre of the Sisal plant, which is, I believe, a species of aloe common to the hillcountry of Ceylon. It may be the poor Walapane villagers will see brighter days cultivating this plant in their aban-

doned coffee gardens."

The statement that no machine to extract the fibre was invented until this year is incorrect, for in Mauritius machines have been invented and have been at work for a good many years. An elaborate paper on the machines and the industry will be found, translated from the French, in the *Tropical Agriculturist*. In the sugar isle the aloe fibre industry has become very important; and we should be glad to get details respecting the best cleaning machine in use there now.—In the Bahamas, too, the industry, which was fostered by Sir Henry Blake, has made such progress that a New Zealand paper writes in this wise:—

WELLINGTON, Nov. 2nd.—The Agent-General has forwarded a letter and specimen of a new species of sisal which is especially grown in the sterile soil, of the Bahamas, where the Governor of the colony is doing all he can to foster its cultivation. Sir H. D. Bell fears it will develop into a formidable enemy of New Zealand flax, as the cost of the dressed fibre hardly amounts to £10 per ton, but the specimen forwarded, which will be sent to Dunedin, is very rough indeed, and fit apparently for coarse matting and cordage only.

If only grubs could be successfully combated, aloe could be grown on hill patanas, too poor for other culture. But profits of £40 an acre cannot be expected. If only one-fourth of that sum could be realized, cultivators ought and no doubt would be satisfied. In the meantime, we trust Ceylon merchants and planters are not to lag behind those of Mauritius and the West Indies, seeing that this island has been described as "a paradise for fibre-yielding plants."

MANGOS.—Mr. Maries, well-known as a collector in Japan for Messrs. Veitch, has now prepared a work on *Mangos*. Mr. Maries is in charge of the Durbhunga Gardens, where he has collected some 150 of the better kinds of Mangos, which are propagated by grafting.—*Gardeners' Chronicle*.

LILY OF THE VALLEY.—The *Illustration Horticole* tells us that the Silesian Railway brings into Berlin every evening during the season truck-loads of these flowers. Each wagon contains thirty baskets, each basket contains 300 bundles, each composed of 100 stalks, that is to say 900,000 per wagon. The little bouquets sold in the streets comprise ten stems, so that each wagon contains 90,000 of them.—*Gardeners' Chronicle*.

"KEW BULLETIN."—The November number contains the Phylloxera regulations at the Cape, already alluded to in these columns; an article on the collection and preservation of fleshy fungi, by Dr. Cookery notes on the Oil-Palm (*Elaeis guineensis*) in Labuan; in which the unfortunate consequences of a "solution of continuity," or change of policy, when a new governor is appointed, are commented on. The Oil Palm was introduced into Labuan several years ago with successful results, but the trees under a new régime were grubbed up, and the work has to be begun again.—*Gardeners' Chronicle*.

COPRA.—In a recent issue of *Notes and Queries* Mr. D. D. Gilder wrote as follows:—

The following coincidence in the vernacular name of the kernel of the coconut in two different languages of the two hemispheres, viz. Samoan and Gujarat (spoken in India) appears to be strange and deserves a place in 'N. and Q.' The Gujarati word is *kopru*, while the Samoan word is *copra*, as will be seen from the following lines taken from the *New York Phrenological Journal* for March, 1889, p. 110: "The chief product of the islands—in fact, the only staple—is *copra*, which is the dried meat of the coconut, and from which coconut oil is expressed."

That *copra* is a Samoan word we take leave to doubt. The Sinhalese is *koppara*, and the word having been adopted by Europeans was doubtless carried by them to the islands of the Pacific.

CEYLON UPCOUNTRY PLANTING REPORT.

THE 'LATE REVOLUTION IN BRAZIL AND ITS RESULTS—
NORTH-EAST MONSOON RAINS AND WEEDING—CACAO—
THE TEA-ROLL-BREAKER—COFFEE—LABOUR SUPPLY.

Dec. 9th.

The north-east monsoon rains still keep off, although we are thankful for the showers which we have got, those who have planted, or intended to plant, have had rather a rough time of it. Weeding contractors are making money; for weeding, which in November is sometimes a little troublesome, has this year been unusually easy. I hear of an experiment of the Indian system of not weeding for six months, and then digging the weeds in, being tried at present on a twenty-acre field. Rama Swami looks rather aghast at this sort of thing, seeing little signs of profitable contracts there; the whole to his mind being too like the effects of hard-up-ness rather than deliberate choice. Still it will be interesting to learn later on how the system has affected the tea, and if it gives encouragement to persevere.

The Cacao crop is still having attention, and the weather we have had has just been perfect for curing. As far as I can learn while there is some disappointment, still on the whole the crop is likely to turn out pretty much as was anticipated. One would be glad to see the borer disappear, but his baneful presence is still about, and unless kept down by careful hunting he would soon ruin the best estate.

The Roll-breaker invented by Mr. Squire of Messrs. Walker & Greig is I understand rapidly getting into favour with tea planters. The principle is a very simple one, and the machine does its work effectively. So pleased was one man with it that he ordered two straight off with the refusal of a third. It is not so elaborate a machine as Mr. Westland's, which also does good work, and gives satisfaction.

Coffee about here is now all gathered, and is not up to last year's crop. There was but one blossom, and when that is the case, it does not stand so much picking, as when there have been three or four. Blossom on the coffee seems as if it would come out now, and if it did it would be quite in keeping with other things which are flourishing out of season.

Coolies are plentiful, and Sinhalese seem to increase. I have great hopes that in time the Sinhalese will become more steady at work and acquire industrious habits. It is a sign of the times, I think, when you hear of a gang of Sinhalese taking employment in one of the higher districts, and where there are no Sinhalese villages, as I did the other day. Those who have worked most with Sinhalese laborer urge patience. "Wait till they get up their strength, is what they say" "and then see if they don't equal the Tamils. The poor returns which they often give is simply owing to the reason that they have been insufficiently fed." PEPPERCORN.

CEYLON TEA IN NEW ZEALAND.

Timaru, N. Z., Nov. 5th.

A. Philip, Esq., Secretary, Planters' Association Kandy.
DEAR SIR,—By last mail I sent you a Timaru Herald of 26th ultimo containing a rather lengthy notice I sent it about tea culture in Ceylon. I sent a copy of the paper to nearly 100 leading people including the proprietors of most of our principal newspapers, and in many cases I likewise sent a packet of your presentation tea per post.

I now send you copies of the Southland News and the Dunedin Evening Star, the former of which reproduced the Herald article in full and the latter

the substance of it, while both speak in high terms of the quality of the tea. The Otago Daily Times thought I wanted a cheap advertisement and took no notice of either tea or article in its columns. I enclose the managing director's letter and copy of my reply.

Any further acknowledgment I get will be forwarded in due course. Private individuals seem to take little notice of the receipt of their packets, which is rather annoying, as the cost of parcel post is 10d per packet. I have the satisfaction of knowing, however, that the demand for the tea is on the increase, and within the last few months I have been able to send orders from several large distributing houses that have not previously bought Ceylon tea. A great part of the tea in this country is sold in 10 lb. boxes or tins made up by blenders who mix up inferior China rubbish with a small percentage of good India or Ceylon. My endeavour has been to convince people that Ceylon tea should be used by itself and if blended at all should be mixed with another grade of Ceylon. That I have met with some success in this is evidenced by the fact that within a month I have ordered, amongst other packages, 750 original 10 lb. boxes.

I mentioned in my last that I have found a few photographs sent me by Mr. Jamieson of Mariawatte and my brother of great service to me in creating an interest in Ceylon tea. I would again recommend the Association in appointing agents in new parts to supply them with a well chosen set of these. Each wholesale house I open an account with, wants them for advertising purposes and I have sent for some to supply their wants.—I am, &c.,

(Signed) R. R. TAYLOR.

Dear Sir,—We are in receipt of yours of 26th instant intimating that you had sent us a packet of Ceylon tea, as also a Timaru Herald giving particulars of the growth of the tea growing and manufacturing industry in Ceylon; which you suggest we should republish.

We cannot quite see our way to advertise the Tea Planters' Association's business gratuitously, and we have no doubt you will see at once that what you suggest is purely advertising. We purpose during Exhibition time having special advertising Supplements, and possibly it may suit you then to have a lengthy notice of the Ceylon tea industry. We anticipate that there will be numerous things of this nature in our Exhibition Supplements.—Yours truly, The Otago Daily Times and Witness Newspapers Company, Limited, (Signed) GEORGE FENWICK, Managing Director.

Copy.

Tea Planters' Association of Ceylon, N. Z. Agency.

Timaru, Oct. 30th, 1889.

The Managing Director, Otago Daily Times Co.

Dear Sir,—I have your memo. of 29th instant, for which I am obliged. The Tea Planters' Association of Ceylon do no business (as an Association) in the way of selling tea. The planters of course individually grow and manufacture tea, selling it in Colombo or shipping to London and other centres. The Association has been formed for the purpose inter alia of procuring information from all parts of the world as to the class of tea required or appreciated in each, and supplying that information to its members. It has lately devoted a large portion of its funds to the purchase of tea for free distribution by its agents, certainly for the purpose of advertising what Ceylon can produce, but also, as I have said, to ascertain the class of tea most suitable for each country, and the members are naturally desirous to know what is thought of these sample of packets. In sending you a sample of Ceylon tea and calling your attention to a few facts I had published in our local paper I had no idea of advertising myself or any individual or firm whatsoever. I thought the fact that an industry of such an important nature having grown so rapidly in a British dependency, rivalling the great staple of China in the quality of its products, might be a matter of public interest in New Zealand as elsewhere. I will be glad to be furnished with further particulars as to your advertising ex-

hibition Supplements cost per column &c. for the use of certain estate owners I represent, but the Tea Planters' Association have nothing to advertise beyond the fact that its members have added another to the great industries of the empire.—Yours faithfully,

(Signed) R. R. TAYLOR.

Copy

Timaru, Oct. 16th.

Dear Sir,—I have been using your Ceylon Tea for some time, and am pleased to inform you it has given my household unqualified satisfaction. It is very pleasant to the taste, particularly the last box which is a delicious flavour. My wife states, she only uses half the quantity compared with the best China obtainable with better results—consequently it is a saving; it is also I consider thoroughly wholesome. If you continue to supply the same quality I will use no other.—Yours faithfully, (Signed) EDW. COOK. (Chief Postmaster.)

R. R. Taylor, Agent, Tea Planters' Association of Ceylon.

THE LATE 'BOOM' IN LOW GRADE TEAS.

The cessation in the strong demand lately experienced for our lower grades of teas in the home market furnishes a useful indication to our planters of the variability of the methods of distribution of their products throughout the United Kingdom, and one by which they will do well to profit in the future. It may well be doubted if there is any article, the sale of which is possessed of so many ramifications as is that of tea. The channels through which it passes ere it reaches the consumer are so numerous, and so sensitive are those channels to the slightest causes of disturbance, that we cannot be too particular in consulting the conditions which produce those causes. A remark very pregnant with useful advice is reported by our London Correspondent as having been made to him by a gentleman intimately acquainted with the subject of tea distribution. Referring to the late decline in the prices obtainable for Ceylon Souchongs, the observation was made that it was impossible for those who live by the mixing and sale of the cheaper varieties of tea to maintain their trade where purchases of Ceylon Souchongs had to be made at elevenpence the pound. This impossibility, we have seen, acted almost immediately and in a very marked degree upon the demand made upon the London dealers, which had, after the cessation of the strikes, forced up the prices in Mincing Lane to an almost—if not quite—unprecedented figure.

A very large proportion of the teas sold in the country dealers' shops are priced as low as 1s 4d per pound, though we have never yet heard of any price below 1s 6d per pound being asked for teas professed to be of Ceylon growth. Now it is evident that, if the latter teas have to be purchased at the public sales in England at 11d the pound, there must be an extremely—quite an insufficiently—small margin, after adding the duty of sixpence the pound, to leave an adequate profit to the retailer who honestly vends Ceylon teas at 1s 6d the pound. That margin, indeed, is but a single penny, and it is manifest it cannot be made to cover more than the mere cost of conveyance and handling, let alone any profit to the vendor. But if this be the case when teas are sold by the pound, the circumstances must act even more deterrently in the instance of sale in packets. We learn that by far the large proportion of the retail trade in our teas consists of the sale of packets. The public regards with more assurance of genuineness those teas which are thus sold and which bear the label of some estate or of some well-known firm of traders. Very frequently, no doubt, such assurance is misplaced, but the fact remains that comparatively few people purchase

their Ceylon teas from the mass exhibited in the grocers' windows. They demand, and are supplied with, the packets bearing marks to which they have become accustomed, and which furnish a guarantee that the taste for particular brands they have acquired will be supplied. It is for this reason that the large bulk of the distribution of our teas at home is in the hands of what is known as the "packet trade."

Now the cost of weighing and packeting in small quantities is by no means an inconsiderable item. We shall not be far out, we imagine, if we state this cost to amount to fully 1½d per pound, reckoning the larger with the smaller packets all round. The small margin available to those who sell from the bulk completely disappears therefore in the case of those who sell by the packet; and not only disappears, but insures the direct loss of one half-penny the pound even without taking into calculation the cost of transport and handling, which amounts probably to fully another penny. We can all see, therefore, how true was the remark made to our London Correspondent that when our Souchongs cannot be purchased below 11 pence, the trade of the retailer either by the weighed pound from the mass or in packet must be brought to a standstill. Such has been the result to the late stimulus afforded to the sales of our lower grade teas by the famine in the market produced by recent strikes. To that cause had to be added another which was no doubt strongly operative towards forcing up prices. This was the late arrival in the home market of the lower grades of the season's teas from India. We are not aware whether there was any special and exceptional reason for this late arrival. Possibly, we should say, it may have been due to telegrams warning the Indian planters not to ship to any amount while the duration of the strikes remained uncertain. At all events, to whatever cause the circumstance was due, it materially contributed to the high prices at which our Souchongs were but recently being sold. Reviewing the whole case, it appears to be manifest that, when the prices of our lower grades of tea rise above ninepence the pound in Mincing Lane, it must act injuriously towards checking the demand for them, and any rise above that figure must consequently be but temporary only. Equally evident is it, however, that the greater proportion of the popular demand in England must always be for teas of about that price. They are the millions who can afford but 1s 6d for tea, —as opposed to the thousands who are willing to pay 2s and 2s 6d—who must ever constitute the bulk of our customers, and this conclusion fully justifies Mr. Roberts' timely-given advice to our planters that it would be a suicidal policy to confine their output to the higher grades only. It is from this point of view too that the prospect of a reduction of the imperial tea duty by 2d—from 6d to 4d per lb. (more cannot be spared)—becomes of real importance to Ceylon planters. It is likely just to afford the safe margin which the "packet-dealers" and their customers require to enable them to deal extensively in pure Ceylon teas at 1s 6d per lb., and we may be sure that when once the taste for such tea is established, there will not be much chance of a recurrence to "Chinas."

"SUNSHINE AND A CUP OF TEA."*

A copy of this little pamphlet, which we referred to the other day, comes to us from Messrs. Geo. Stewart & Co., who write:—

"We beg to send herewith a copy of a little brochure by Mr. George Russell, entitled 'Sunshine,' &c., which he requests us to pass on to you with his compliments.

* Publishers.

Mr. Russell, we may mention, spent some months in Ceylon about a year ago, and saw a good deal of our upcountry districts. He has been led to publish an account of his visit to the island partly in the hope that it may in some way help to make Ceylon tea more widely known than at present, and if for no other reason, we would hope that this will insure for it a favourable reception."

Mr. Russell's brochure of some 30 pages large type is printed on toned paper bound attractively in green, and will no doubt have a wide circulation in the old country, his very brief account of a visit to Ceylon and of our tea industry being written after a lively as well as clever fashion. Milton's well-known line is however as usual, quoted wrongly on the first page, "fresh fields and pastures new;" while the great poet wrote, "Tomorrow to fresh woods and pastures new." The greater portion of the little book is taken up with a sketch of our planting industry and the figures for tea, but put in such a way as to be attractive to home readers. As a specimen of the more general part of Mr. Russell's essay we quote as follows:—

In an island of but one-half the area in square miles, and inhabited by but one-twelfth of the population of England, I have found subjects which, I think, cannot fail to interest and delight all sorts and conditions of travellers. Ceylon has been described, and well described, and, on the high road to so much rich land of colonization, is visited by probably as many passing travellers as any of our Colonies, but the descriptions are read as of inaccessible places far away beyond the seas, and, as a rule, the visitor drinks 'and rises away.' A halt of twenty-four hours in the harbour of Colombo allows time for a dinner at the Grand Oriental Hotel (commonly known as the G. O. H.), the doubtful enjoyment of a drive in a 'Rickshaw,' the opportunity to bargain for a stone which may or may not prove to be a sapphire, a scamper by the train to Kandy, with possibly an hour to spare for the incomparable Botanic Gardens of Peradeniya, and then the traveller hastens on his way to his floating home, to record in his journal, to write home to his friends, to cherish the delusion in his own mind for all time, that he has seen Ceylon.

'Beautiful vegetation,' he writes and thinks, 'a lovely spot, but very small and quickly seen.' More than once have I heard this description, but how far it is from being true only those can tell who have gone through the length and breadth of the island. The scenery along the line of railway from Colombo to Kandy is undoubtedly full of objects of strange tropical beauty, by which none can fail to be impressed, but nothing short of travel and residence in the interior can fairly prove the right of Ceylon to be regarded as one of the richest and rarest gems in the precious Crown of the Empress of India. * * *

For the artist, the field is inexhaustible. Sunrise and sunset beautiful beyond all imagination; flashes of light, density of shadow, flush and variety of colour, rarely to be seen in any other condition of atmosphere; forest and jungle giving endless subjects for the painter's brush, delighting the eyes with variety of foliage and with brilliant blossoms set like jewels in a network of dazzling green.

'There is continual Spring and harvest there, Continual, both meeting at one time:

For all the boughs do laughing blossoms bear,

And with fresh colours deck the wanton prime.'

For the sportsman there are far greater opportunities of varied sport than I believe to be generally known, as the following list of game to be found will show:—elephant, elk, bear, buffalo, wild boar, spotted and other deer, cheetah, monkeys, wild cat, hare, jungle fowl, wild ducks (innumerable varieties), pea-fowl, spur-fowl, partridge, and snipe. All the above, and others, are to be found on the plains, on the mountains, and in the jungle, where is to be seen the varied foliage of the tamarind, calamander, ebony, coconut palm, satin-wood, toon, acacia, sapan-wood, rain tree, eucalyptus, lak wood, mulberry, pootra or tulip tree, kadumberiya, ficus religiosa, and others which I cannot venture to enumerate. Mangoes, melons, plantains, lime, pineapples,

oranges, guavas, pumelos, sour-sops, figs, custard apples, rambutans, are among the fruits. Birds of brilliant plumage, butterflies, endless in variety, and dazzling in their tropical splendour,—an insect world of which the name is legion,—are there to be found living amidst a luxuriance of flowers and spice-bearing plants which perfume the air. * * *

And finally:—

Should any of the readers of these pages be attracted by what I have said to visit Ceylon with any one of the objects to which I have referred in view, I feel satisfied that they will, on leaving, exclaim, in the words of the traveller, Marco Polo,—'It is the finest island in the world!'

The thanks of all interested in the prosperity of the island and of "tea" are undoubtedly due to Mr. George Russell for "Sunshine and a Cup of Tea."

THE EXAMINATION OF PEARL BANKS BY MEANS OF THE ELECTRIC LIGHT

is an attractive idea and seems feasible enough. The results of experience, however, are opposed to the idea, the British authorities consulted at the instance of the Madras Government only making a reservation in favour of a lamp carried under water by a regular diver, while in the United States there was scepticism even in regard to such a use of the light. As some years ago we saw a detailed account of a small vessel being sent out fitted with the electric light for employment in the Australian Pearl Fisheries, we are specially surprised to find in the papers supplied by the Madras Government distinct statements that no such use has even been made of the electric light.—Mr. Edgar Thurston of the Madras Central Museum, when at home in Nov. 1885, made inquiries and wrote to the Madras Government:—

I, in the first place, had an interview with the Edison and Swan Limited Electric Light Company, who have written to me as follows:—"With reference to your personal inquiry today in regard to the practicability of using the electric light for the purpose of observation of the state of the sea bottom in pearl-fishing districts, we do not think that there would be any very great difficulty in obtaining this result. A powerful arc light enclosed in a strong glass lantern made water-tight, or an incandescent lamp of high candle power (say from 100 to 200 U. P. actual) would enable the diver to thoroughly explore the condition of matters at the bottom. The current for the light would, of course, have to be supplied by a dynamo driven by a small separate engine, and heavily insulated cables would convey the current to the lamp. At the depth to which you refer (some 20 fathoms) we do not think that the light could be used for making observations from the surface of the water. If it were found practical to attach the lantern containing the electric light to one end of a very long tube (which could be made in lengths of, say, 20 feet and screwed together when required for use) then in still water excellent results could no doubt be obtained by the use of even a 50 U. P. incandescent lamp. The bottom section of the tube would, of course, be fitted with a strong water-tight glass cover, and the lantern arranged to reflect the light across the bottom of the tube. An ordinary field glass could be fixed to the top of the upper section, and an excellent view of the state of matters on the sea bottom would thus be obtained. This plan would be very easily carried out in shallow water, but we cannot, of course, say what degree of success would be likely to attend it in 20 fathoms. The chief difficulty, as it seems to us, would be the use of a tube of such great length. We should be glad to supply incandescent lamps of suitable candle power, but we are not ourselves makers of arc lamps.—24th Oct. 1885. While staying in Liverpool recently, I had the opportunity of having some conversation on the subject of submarine lighting with Professor Herdman, Honorary Director of the Puffin Island Biological Station, whose experiences during a recent dredging cruise on the Liverpool Salvage Association S. S. "Hyena" are

a deposit consequently takes place on the inner surface of the globe. This, however, does not affect the power of the lamp until after four or five hours' use, and can easily be removed when new carbons are supplied. Arc lamps can be made so as to burn in any position, and the additional initial cost being small relatively to the increased power, such a lamp would appear to be preferable to the incandescent lamp. It is a question, however, how far an electric light would assist an observer at the surface in making observations or objects at the bottom of the sea. On dark nights it would no doubt be extremely useful, but in the day time the difficulty of accurately observing objects at any considerable depth in ordinarily clear water is caused, not by the insufficiency of light, but by its refraction and reflection, a difficulty which is increased where the surface is not calm. This difficulty can be obviated by the use of a water telescope, but the objection to the use of this instrument is that it is not easily used except in fairly calm water, and that the actual area in view at any given moment is of course limited by the "field" of the glass. Where the water is at all thick the water telescope is useless (at any rate at any considerable depth), and the use of the electric light would probably then be found of no help to it whether by day or by night. Given clear water, on the other hand, the electric light would no doubt prove of great value in facilitating observations at night, when it would probably be found that the use of the water telescope could be dispensed with. This would almost certainly be the case in a calm sea, and in the absence of moonlight, and it is probable that even on moonlight nights and with a ruffled surface, the illumination of the bottom by a powerful lamp would be sufficient to counteract the effects of reflection (though hardly of refraction) without the help of the water telescope. I venture to suggest that the observations which the Government of Madras desire to make upon the habits of the pearl oyster would be greatly facilitated by the employment of a diver equipped with an ordinary diving dress. By this means a prolonged stay could be made by an observer on the sea bottom who could not only make an accurate survey of the bed, but could periodically examine the same ground, select specimens and make minute observations, which would be impossible to an observer at the surface, and are equally impossible to a native diver, whose stay at the bottom is limited to a minute or so. The use of a diving dress, in conjunction with the electric light, would render the observer almost independent of the transparency of the water and of day or night.

Lord Cross writing on 7th March of this year stated:—

It will be observed that the opinion of the United States Commissioner of Fish and Fisheries practically coincides with what of the other experts, being, in effect, that the utility of the electric light for the purpose in view is doubtful, but that such a light would be useful to a diver. The information obtained seems not to afford much encouragement for pursuing the inquiry further.

Amongst the enclosures was

A letter from the United States Commissioner of Fish and Fisheries to the Secretary of State, relative to experiments in submarine investigations made by officers of the United States Fish Commission Steamer "Albatross," together with a report on the construction and outfit of that vessel by Lieutenant Commander Tanner, of the United States Navy.

The Commissioner stated:—

In order to test the usefulness of electric light in connection with submarine work, from both a practical and a scientific standpoint, the Fish Commission Steamer "Albatross" was supplied with a complete electric plant, according to the Edison incandescent system, and with sufficient power to work also two or three arc lights in circuit with the smaller lamps. This plant was fully described in a report prepared by Lieutenant Commander Z. L. Tanner, United States Navy, commanding the steamer "Albatross," and a copy of the same is herewith respectfully transmitted.

About a year ago smaller and improved forms of dynamo and engine were substituted for the original ones. This plant provided for the lighting of the entire ship, as well as for submarine illumination, and its cost was much greater than would be that of a smaller outfit intended for the latter purpose only. Moreover, our experience would indicate that the electric light is entirely unsuited to the researches described in Lord Salisbury's letter, namely, to study the habits of the pearl oyster in depths of 10 to 12 fathoms from the deck of a vessel.

The submarine light of the steamer "Albatross," as originally constructed, consisted of three Edison incandescent lamps fixed to a brass plate which later formed the base of a double glass globe enveloping the lamps. It worked well down to a depth of about 200 feet, below which the fastenings of the globe were unable to withstand the pressure of the water. Since the first year from one to three unprotected Edison lamps have generally been employed, and have been successfully lowered to a depth of 150 feet, though seldom used below a few feet in depth. The greatest depth at which the light can be seen varies with the clearness of the water, but under ordinary circumstances it disappears below 60 or 70 feet. Objects swimming in the water about the lamps cannot be distinguished at that depth. One of the most favourable opportunities for testing the efficiency of the lamp below the surface occurred among the Bahamas islands, where the "Albatross" usually anchored in depths of 30 to 40 feet. The water there was clear, and the bottom consisted of white coral sand. When the lamp was lowered upon such bottom it could be plainly seen, and also the position of all dark objects near it, but the character of the latter could not be determined from the steamer's deck. The lamp is now seldom employed except within a foot or two of the surface where it serves to attract some kind of fishes, and other marine forms, which may then be captured in nets or by means of hooks. I would suggest, however, that the electric light might be utilized to illuminate the beds of pearl oysters so that the observer making use of the diving bell could readily study the habits of that mollusc. I do not believe that it could otherwise be made of any service in that connection.

On 28th March of this year Lord Cross wrote:—

It will be seen that the results obtained from the Admiralty experiments continue to afford little reason for thinking that the electric light could be successfully used for the purpose in view, even in conjunction with a diver. A 2,000-candle power arc lamp, taken down by a diver, rendered articles on the sea bottom visible at a distance of not more than about three yards from the bull's eye of the lantern.

The letter from the Admiralty stated:—

From lamp of 2,000-candle power, burnt from a Siemens dynamo, with a current of about 35 amperes, could see an article on the bottom in 6½ fathoms at a distance of about three yards from the bull's eye of the lantern. A 50-candle power incandescent lamp used under similar circumstances in clear water enabled objects to be seen 2 or 3 feet from the light. Further experiments made in the present year at night at Spithead indicate that the shape of a white object may be distinguished from the surface at a depth of 8 feet when a 50-candle power incandescent light, fitted in a tube with a glass bottom, so that its rays were projected downwards, is lowered to within a foot or two of it. The white color could be seen at 12 feet, and the reflection of light in the water when the lamp passed directly over it at considerably greater depths, the water being 16 fathoms deep. It appears probable from these results that, in perfectly clear water, and using a powerful light, objects might be distinguished at a slightly greater depth at night than under favourable circumstances in the day time.

The lamps used were of no service in daylight.

The Madras Board of Revenue thereupon recorded a resolution—dated 28th May 1889:—

The papers on the use of electric lighting for deep sea-working will be returned to Government with the letters and notes furnished by Messrs. Thurston

and Phipps and an expression of the Board's opinion, that in view of the reports received from England, and the fact that the steam engine on the "Margaret Northcote" is not sufficiently powerful to work the apparatus necessary for electric lighting, they do not feel justified in recommending that any experiments of the kind suggested be made. If, hereafter, from experiments made under suitable conditions, it should appear that it will be useful to conduct the pearl fishery, with electric lighting, it can be adopted. But neither the agency nor the engine power at the Board's command is suitable for conducting experiments. It will be observed that this opinion is virtually concurred in by Mr. Thurston and Mr. Phipps. Mr. Thurston referred to his former opinion that, "should experiments be carried out and proved that material advantage is not obtained by the use of the electric light at depths of 10 fathoms and upwards, the experiments carried out by Professor Herdman, with whom I conversed on the subject, nevertheless, show clearly that the electric light is a most valuable adjunct in connection with scientific dredging. Leaving, however, science out of the question and considering submarine electric lighting solely from the standpoint of its practical use as regards pearl fishery operations, I feel convinced that the expenditure, which would be incurred in the purchase and maintenance of the necessary apparatus, would not be justified by the results obtained. I have read carefully through the correspondence forwarded to me and the most practical observations seem to me to be those made by Mr. C. E. Fryer, Inspector of Fisheries, who, while referring to the absence of any direct experience upon the point to which the Madras Government refers, says:—'I venture to suggest that the observations which the Government of Madras desire to make upon the habits of the pearl oyster would be greatly facilitated by the employment of a diver equipped with an ordinary diving dress. By this means a prolonged stay could be made by an observer on the sea bottom, who could not only make an accurate survey of the bed, but could periodically examine the same ground, select specimens, and make minute observations, which would be impossible to an observer at the surface, and are equally impossible to a native diver, whose stay at the bottom is limited to a minute or so.' To these remarks I may add my own experience, when recently engaged at the Tuticorin and Ceylon fisheries, where, by examination of the shells of the oysters brought in by the divers by expending small sums of money which tempted the native divers to bring me such marine animals (corals, star-fishes, sponges, &c.) as they met with at the sea-bottom, by conversation with the European diver, who was further able to bring up large coral blocks for examination, and by dredging, I was able to form a very good idea as to the conditions under which the pearl oysters were living."

Mr. Phipps stated:—

"I am not aware what good result is likely to be gained by the use of an electric light on the Tuticorin pearl banks: when examinations are made it is always during fine, and, if possible, calm weather when the strength of the sun's rays penetrates to the bottom of the sea, enabling the divers to distinguish the various shells, &c, of which they are in pursuit, it is never found convenient to work at night, nor would the divers care to do so. In respect to the clearness of the sea, although it happens that from the deck of the vessel you can watch a diver descending until he reaches the ground level, he is then quickly lost to the view as the water is easily disturbed. I have no doubt that on a dark night an electric light lowered from a ship's side, if the water was quite clear, would enable the bottom to be observed, but what good would result from this when we already possess reliable information gleaned from both helmet and native divers. I may add that the water on the Timinevelly coast is never so clear as it is at the Laccadive or Chagos islands where the absence of anything like mud or river drainage keeps the sea quite bright: at these islands I have often watched fish swimming in and out amongst the

corals in from 10 to 15 fathoms depths and playing around the vessel's anchor; this can never be done on the coast. As really there is no necessity for obtaining this electric light apparatus and no profit from its use likely to accrue, I am of opinion that it would be a very useless expenditure, the Steamer "Margaret Northcote" could not be used unless entirely refitted with a costly set of new engine and boiler. The water telescope is by no means easy to use as there is nearly always some motion on the banks any the field of observation small. I have often watched the bottom when at the Laccadive islands through the glass side light in the cabin of the "Margaret Northcote" as the vessel rolled in the heavy swell and was surprised how clearly things down below could be distinguished. I would suggest that if a sheet of thick glass could be let into the lower plates of a vessel and there protected both out and inside in some way from accident, a study of the sea bottom in clear-water either by day with the sun's rays or by night by the use of a powerful electric light could be made. This may appear a rather wild suggestion, but I believe it would be found wonderfully useful."

Either this, or the use of oil on the surface of troubled water, seems the most feasible mode of examination, apart from sending divers down.

Lord Cross finally sent the replies from Australia:—

From Thomas W. Smith, Esq., Inspector, Pearl Shell Fisheries.—The electric light is not used in the pearl shell fisheries of Western Australia nor have I heard of it being used in connection with the fisheries on any part of the Australian coast.

From Captain C. R. Russell, R.N., Chief Harb or Master.—I am not able to find that hitherto the electric light has been used for the pearl fishing in South Australia, either to gather shell or to observe the habits of the oyster. Mr. Clark has lately returned from the other colonies, and states, in a letter herewith, that he has never known the electric light used for the pearl fisheries in any Australian waters. Captain Smith also states above that he has never heard of it.

From James Clark, Esq., to Captain Russell, R.N. dated Fremantle.—In reply to your inquiry about the use of the electric light in the pearl fisheries, in Australia, I have to say that I have never known it used in the fisheries, nor is it required. The habits of the pearl oyster could be studied without its use, while for working, were it required, its cost would not allow it to be used profitably. I have been pearling eight years.

After all this it is not surprising that the "Order" of the Governor of Madras should be:—

After a careful consideration of the papers read above, His Excellency the Governor in Council has come to the conclusion that the project of employing electric lights in connection with pearl fisheries should be abandoned, and resolves to inform the Right Honourable the Secretary of State for India accordingly.

We made the above lengthy extracts because of the general as well as local interest of the subject. We have found it difficult to make room for the matter; but, in view of the announcement of an important pearl fishery, we devote a special supplement to the publication of the correspondence, adding other interesting matter.

CACAO, &c.—THE TRINIDAD "AGRICULTURAL RECORD."

We have received the first number of this periodical, which has been started as the organ of a Central and District Agricultural Boards, which have been formed for the better promotion of those improvements in agriculture in regard to which the Governor, Sir W. Robinson, has shown so much interest, and which he has done so much to further. The scope of the "Agricultural Record" will embrace reports on botanical, chemical and agricultural

topics of general interest to merchants and planters. It is to be published as nearly as possible on the 15th of every month, or within two weeks of the meetings of the Central Agricultural Board. The editor in his introduction remarks:—

In concluding this article it is meet and proper to observe that the vigorous action of the Government in promoting the present movement is quite in keeping with the policy of Government in every part of the world. Voluntary effort is insufficient. In England a Minister of Agriculture has been recently appointed, in Cape Colony there is a Government Department of Agriculture as well as a Journal, and in this Colony the people require to be impressed with very different ideas from those mentioned in Sir William Robinson's inaugural speech, viz., that "agricultural pursuits are, in too many cases, regarded as degrading." His Excellency quoted George Washington, who said that "Agriculture was the most healthful, the most useful, and the most noble employment of man." Fond and foolish parents who think that a planter's life is not sufficiently genteel for "young hopeful" and cripple themselves to support their boys in Europe through a long and expensive course of study to qualify for one of the learned professions should bear in mind this wise saying of the most honoured President that America has ever had, and remember that Law, Physic and Divinity, overstocked as they are, and depending so much for success on family connections or interest and influential friends as on the ability of the young aspirant, can offer no surer road to happiness and independence than Agriculture.

It is gratifying to us to see our publication, the *Tropical Agriculturist*, made the subject of the leading article, and so highly appreciated as the following extract indicates:—

THE "TROPICAL AGRICULTURIST."*

This Journal has been strongly recommended to the Local Agricultural Boards and others as the best current periodical treating of Tropical Agriculture, and anyone may satisfy himself of the wisdom of this advice by referring to the very complete Index published in the June number (to be found in the Public Library); this number completes the Eighth Volume, and it will have to be confessed that its scope is quite encyclopædic, its contributors practical and accurate, and in every way it might serve as a model of what could be done in "Trinidad," if every one would take the excellent advice given by Mr. Hart in his second Lecture, "Our Work," and pull together for the common good.

Various products are then discussed, such as tea, which cannot be grown profitably in Trinidad any more than sugar on a large scale can be grown to pay in Ceylon; coffee, which can and ought to be cultivated extensively in Trinidad; cacao, which is grown in both colonies; coconuts and pepper. This article and others will be quoted in the *Tropical Agriculturist*. In consequence of the *Erythrina*s having been badly injured by locusts, a new shade tree for cacao was being discussed. The botanical name is not given, only the local term *Apomata*, but it is said to resemble *Cordia gerascanthus*. There is a long and interesting list of Native Medicinal Plants. One is thus noticed:—

Herbe à Pique, *Fr.* Calea Lobata, *Botan.*—This latter plant I regard as a good succedaneum of the cinchona; in fact, as good as any which can be mentioned. But so bitter it is that it must be administered in some spirit, rum for instance, or in powder. The whole plant may be used.

Legislation for the repression of the destructive insect known as the "parasol ant" was the subject of considerable discussion. With reference to a proposal for establishing a local agricultural bank, the staple industry was thus referred to by a speaker at a meeting:—

* "The Tropical Agriculturist"—A. M. & J. Ferguson, Colonibo, Ceylon; London Agents, John Haddon & Co.

Our large Cocoa estates derived most of their capital from the English and French merchants. Basing his calculation upon the Cocoa industry, he saw that we exported 120,000 bags of Cocoa. He calculated that one-third of that Cocoa was pledged for advances or other debts abroad, and there remained some 80,000 bags for which the cost of production was supplied from capital in the island, either from individual capitalists or the Colonial Bank through intermediaries. If they took the cost of production and cultivation of the Cocoa trees, including the young trees not yet bearing, he would put it at \$10 per bag (subject to correction). That would be \$800,000—a sufficient margin for a bank to begin with.

An article on the "Fibre Industry" will be reprinted in the *Tropical Agriculturist*.—We shall look with interest for future numbers of the Trinidad "Agricultural Record."

THE COTTON FROM WATTEGAMA, sent by a correspondent, is reported on by the Hon. W. W. Mitchell as follows:—"I took the sample of cotton to the mill yesterday and ginned some, and now send you a little of it. It is white Egyptian, of fair staple, but a little stained as you will see: 30 cents a lb. free from seed is the value at any railway station for any quantity."

THE GOVERNMENT QUINOLOGIST.—We learn that the services of Mr. Hooper, the Quinologist, will be retained by the Madras Government, but not on the terms of his covenant. He will be placed on the Uncovenanted list, and his emoluments and allowances be regulated by the rules of that service. It is hoped the arrangement will enable him to complete the various experiments inaugurated.—*South of India Observer*.

CYPRUS.—General Sir Robert Biddulph, Governor of Cyprus, in an address before the British Association, gave a detailed account of the geographical features of the island. The whole of the forest lands of Cyprus occupied an area of 400 square miles. When the British entered into occupation, the ravages of the wood-cutter were in full operation, and it could not be doubted that the final destruction of the forests was only a question of time. Then goats were very destructive to the forests, destroying the trees where they were allowed to pasture unrestrictedly. While in Italy the number of goats was 16 per square mile, in Cyprus the number was 64 per square mile, and 1430 for every 1000 inhabitants. The destruction of the forests produced climatal disturbances, and diminished the wealth and productiveness of the island. The Locust plague increased wherever the forests were destroyed. The farms were all worked by their proprietors, and the consequence was that there were no wealthy persons and no beggars. There were in the island 600,000 registered holdings of real property—that was to say, more than three for each inhabitant.—*Gardeners' Chronicle*.

WEEDS.—Herbs and flowers which grow where the agriculturist or the gardener does not want them, form the subject of an article in the October issue of the *Cornhill Magazine*. The greater part of our existing weeds are (observes the writer) contemporaries of the stone and bronze age, and came to us, like civilisation, from the remote East, with the introduction of Corn and Barley. When man had cleared the primeval forests, the wild herbs and flowers accustomed to live under the shade of trees were exposed to the open heat of the noonday sun, and died out, and a vegetation from elsewhere began to usurp the soil. In America, where the substitution is a thing of such very late date, the two floras, native and intrusive, can be traced with perfect ease and certainty. European weeds of cultivation have taken possession of all Eastern America, to the exclusion of the native woodland flora, almost as fully as the European man, with his horse and cows, has taken possession of the soil to the exclusion of the noble Red Indian with his correlative buffalo.—*Gardeners' Chronicle*.

Correspondence.

To the Editor.

TOPPING COTTON PLANTS.

SIR,—Will you or some of your readers kindly inform me if Sea Island cotton ought to be topped. I hear it has been done in Matale; but my kangannies, who come from a cotton-growing country, say that "topping" cotton prevents it from blossoming properly. Any information will oblige your obedient servant,
IGNORAMUS.

TOPPING OF TEA ISLAND COTTON.

SIR,—In reply to your correspondent who asks if Sea Island Cotton ought to be topped, I would recommend him to top them down to about two feet in height, if they have grown up and borne crop, and they will soon shoot up again and blossom. Of course if the plants are young and have not attained their full height, they should not be touched. The experience of the kangany he refers to has probably been confined to Tinnevely kinds.—Yours faithfully,
W. W. MITCHELL.

LIBERIAN COFFEE PLANTS FROM SUCKERS?

Nangoeng, November 12th.

DEAR SIR,—Will you kindly give space to the following question in your periodical the *Tropical Agriculturist*: "Can Liberian coffee be grown from suckers?"

I tried it many years ago without the least success, and am now told that the thing is well possible.

I should feel very much obliged to anybody who may be so kind to communicate his experience about the matter.—Yours truly,
E. K.

THE MORNING POST ON "PLANTER ENERGY" AND COFFEE AND TEA IN CEYLON.

Waddesdon House, Bletchley, Nov. 22nd.

DEAR SIR,—By this mail you will no doubt receive a copy of the *Morning Post* of the 20th inst. As soon as I had seen and read the article I called in Wellington Street, with the hope that I might obtain the ear of one of the editorial staff and so continue the important subject, but the hour (noon) was not propitious.

We planters are of course somewhat sore that bug should have been left out of the question,* for I believe that I am right in saying that leaf disease *per se* never killed King Coffee? I went all round my estate with Mr. Marshall Ward, and if he sees these lines he will remember the doubtful hospitality which I inflicted upon him, and he assured me that with nitrogenous manures I could get a lot of crop out of the estate and I do not think that he ever said leaf disease would kill directly. †

I have written to the *Morning Post* to give the actual figures of exports and your estimate for the current season. It was suggested to me that there was confusion between the calendar year and the export season, but the crop 1874-75 given, 988,328 cwt., agrees with the figures in your Directory for coffee secured from plantations only. From the same source the writer of the article might have learnt that the million was thrice topped in the "sixties."

* But our correspondent himself forgets the formidable white grub.—Ed.

† No amount of nitrogenous manure was able to preserve coffee in a steadily bearing condition except in a very few exceptional cases.—Ed.

I have also tried to point out that we—the Ceylon planters—cannot be accused of over-production, for 1,000,000 cwt.=112,000,000 lb., and should our most sanguine expectations be realized and the tea export reach 100,000,000 lb. we are still short by 12,000,000 lb. of food commodity of the crop 1874-75 referred to.

Regard also the consumption of tea and coffee from a British point of view—the consumption of tea is largely in success of coffee. The taste of the public then must be in favour of tea from its simple preparation and comforting qualities. Give them good Ceylon tea and they will not return to old acquaintances, as the writer of "Planter Energy in Ceylon" remarks. It is certainly a strong point in favour of our enterprise that work has again been given to the Tamils, for there is a strong bond of union between the inhabitants of Southern India and Ceylon, and planters will all agree that we miss our coolies when we are away from them in the west. Not long since the *Standard* (Oct. 1st) had a leading article on servants, and they paid a handsome tribute to the Asiatic. The danger of going "fantee" occasionally is fully compensated by the great attention and simple wants of a good Madrassee, Tamil, or Sinhalese. Whether we are quite exempt from "fantee" proclivities in the west is an open question. I have heard of "alcoholic disabilities" amongst the ladies and gentlemen who are so kind as to prepare our dinners and serve them!

But to return to tropical agriculture:—From what it says in this article under discussion, "Today the demand is in excess of the supply, and joy has returned to the bosom of the Ceylon planter," one may venture to predict a boom in Ceylon tea as there has been in coffee, and the question will be how to spread the sail to the leading wind. We cannot be too cautious. The slightest sign of too general cultivation should be regarded with suspicion. How came the coffee to be diseased? And if it is to be planted again I trust it may be done on steady lines—a hole big enough for a cooly to sit in is better than a hole only fit for the reception of a fence stake or sheep hurdle. Again there is some limit as to the number of plants of any product that an acre will bear. Cabbages can be planted 4,840 to the acre, but they are part of a rotation of crops, and generally have in this country at least 15 or 20 cartloads of good rich manure to assist them, and they are sometimes eaten by stock on the ground. "Tea has stepped in where coffee feared to tread:" the adaptation is suggestive. Whoever wrote the article has done Ceylon a signal service, and I trust that the Colony will in future receive the attention it so justly deserves in all things. Whatever may be the poetry in connection with it, the prose advantages political and topical are worthy of more than ordinary attention.—I remain, yours faithfully,
ARTHUR O. ISHAM.

P. S.—In France I am credibly informed good tea costs from 7 to 10 francs—say 6s 8½d—which is more than double what you calculate for England, viz. 2s 9d. In other words tea in England costs a farthing a cup, in France one halfpenny. Give the thrifty French working man cheap tea, and then how about over-production?

Constitutional Year-book 1889.

Consumption of Imported Food: Table 69.

	1870-74.	1875-79.	1880.
Coffee	0.98	0.98	0.92 lb.
Tea	4.02	4.56	4.59 lb.

In 1887 Coffee 0.79, Tea 4.95 lb.: retained for consumption annually per head of the population.

The following is the article referred to :—

PLANTER ENERGY IN CEYLON.

Tradition connects the island of Ceylon with Adam and Paradise, but its financial and commercial history, so far as Europeans are concerned, do not commence until somewhere about "the stately times of Great Elizabeth," when the Portuguese formed settlements there. Ceylon is an island of romance. Not only romantic of herself, this "pearl of the orient" is the cause of romance in others. She has figured a good deal both in lay and religious poetry in connection with spicy breezes and precious stones. The very name still conjures up before the imaginative nostrils an odour of cinnamon and cedar wood, and visions of pagodas and Buddhist temples. It was there, as readers of "The Arabian Nights" will remember, that Sindbad the Sailor met with some startling adventures. But although Ceylon has filled a very respectable place in fable, history and romance for the last 2,000 years, the English were not practically interested in the famous island until they took it from the Dutch in 1795. Some 25 years or so after this, Ceylon having become a Crown Colony, divorced from her temporary connection with the Presidency of Madras, a number of enterprising men, chiefly Scotch, settled there, with the object of opening up the country for their own advantage. Not many years elapsed before large fortunes began to be made by planting coffee. Labour, chiefly that of Tamil coolies, who came from India, was cheap and plentiful, and the soil was suited for the growth of a berry which tradition connects with Mocha, but contemporary importables with Brazil. Coffee had a brilliant innings; the soil seemed inexhaustible and the sanguine planters did not hesitate to make the greatest demands on its fecundity. In "the sixties" there was a "boom" in Ceylon coffee, and a number of young Englishmen went out there in the hopes of finding a swift road to riches. Their hopes, unfortunately, for the most part were not destined to be realised. Hitherto the plantations had been turning out coffee with almost mathematical precision. There were better crops and worse crops, but they were always paying crops. The planters expected to make money and were disappointed when they did not make it fast enough. But Nature is a capricious mistress, and it seems that they had wooed her with too much ardour. Whether the soil became exhausted for coffee crops or the epidemic that settled on the trees arose from causes beyond planting control, we do not know, but leaf disease, which had shown itself only on a few estates, began to spread across the island with ominous rapidity. Then there commenced a determined struggle between the planters and their relentless foe. Everything that science could suggest or ingenuity invent was employed against him. Still leaf disease spread until, slowly but surely, some of the best plantations on the island were destroyed, and their owners left burdened with many acres of their valueless land mortgaged to a hopeless extent. The island was already considerably in pawn to the capitalists at home and in Holland; and the security was steadily decreasing in value owing to the advances of an insidious foe. The rapidity with which the disease spread from plantation to plantation is evident from a few figures. In 1869 176,467 acres of coffee were under cultivation. In 1877 this had increased to an acreage of 272,243. But from that point the descent was rapid. Coffee died off in spite of every effort. At the present moment, therefore, the leaf disease, in rough numbers, has destroyed 222,243 acres of coffee in 11 or 12 years. This is an excellent example of the devastating power of Nature in her milder aspects of destruction. Only those familiar with the vicissitudes of the prolonged and arduous struggle can realise how much energy, labour, and capital have been consumed to no purpose. In 1874-75 Ceylon exported 988,323 cwt. of coffee; in 1887-88 the estimated quantity had sunk to 150,000 cwt. Many communities would have succumbed entirely under the unequal contest. Fortunately Ceylon planters are men of remarkable enterprise, and as coffee was killed they turned their attention to other pro-

ducts. Cinchona, cocoa, cocaine have been widely experimented on, but none of these offered the same road to wealth to which coffee used to point. One lucky day, however, it was discovered that Ceylon probably possessed the best soil and climate in the world for growing tea. The history of the last few years of Ceylon planting may, therefore, be briefly written. Exit coffee; enter tea. There is something dramatic in this sequence of the universal beverages. In the old-fashioned comedy, when the young man is ruined and the lady who adores him is in despair, the wealthy uncle from India, with his lacs of rupees and a liver as diseased as that of a Strasburg goose, used to arrive on the scene and scatter wealth and prosperity about him. Such a relative the Ceylon planters have discovered in tea. Tea has stepped in where coffee feared to tread. In 1867 it is said 10 acres of land were planted with it. In 1874 there were 350 acres. In 1888 there were 183,000 acres of land under tea, and in the same year 22,000,000 lb. were exported, chiefly to England. The estimate for the present year is 43,000,000 lb. It has taken some time for the tea-drinking public to discover the excellence of Ceylon tea. A year or two ago the planters dreaded over production. With China and India to compete with tea, they thought, might become a drug in the market. Although the consumption increased yearly, it is outstripped by the production. Would it pay to grow tea at the price over-production threatened to lower it to? So far as Ceylon is concerned, this problem has been solved. In proportion as the planters bestowed care on the quality, it was found the demand for it increased. Whether it is better than China tea is a question on which experts differ, but at the present moment the public prefer it to any other. Today the demand is in excess of the supply, and joy has returned to the bosom of the Ceylon planter. It is doubtful, of course, whether the present high prices will be maintained. That depends on the consumer, but he is not capricious in such a question as tea drinking. He buys the article that suits him best, and there is no reason, when he has acquired a taste for Ceylon tea, why he should discard it for the teas of India or China, with which he has been acquainted all his life. It is scarcely an exaggeration to say that the success in tea planting has saved Ceylon from something like bankruptcy. Many thousands of Tamil coolies, whose means of making a livelihood the extinction of coffee once threatened, are now employed on the numerous tea estates, and once more all is prosperous and hopeful. Everything points to the still further development of the Ceylon tea industry. As we pointed out above, the estimate for the current year is more than double the amount exported last year. The process of converting old coffee estates into tea gardens is actively carried on. In 1888 there were 183,000 acres of land under tea against 50,000 acres under coffee. In 1877 the area under coffee was 272,243; at the present rate of increase that will be surpassed by tea. The soil of Ceylon is not rich as we understand it in England; but it is admirably suited for tea. The peculiar aromatic and pungent flavour it possesses is due to the ferruginous character of the land. Tea, like wine, naturally acquires special qualities from its environment. The soil, moreover, possesses with other peculiar attributes the depth that is essential. It is not probable that any such calamity as destroyed coffee will befall the tea plant, which in Ceylon is peculiarly hardy. The last planting success in our beautiful Asiatic Colony is most gratifying to Englishmen, who must feel, when they are drinking Ceylon tea, that they are in their small way helping to increase the prosperity of men whose enterprise and courage merit the success they have earned.—*Morning Post*, Nov. 20th.

ALL ABOUT TOBACCO" AS A MANUAL OF INFORMATION.

Bandarapolla, Matale, Nov. 23rd.

DEAR SIR,—On looking over the accompanying November number of the *Tobacco Trade Review*, at page 316 I find a long and interesting review of that excellent compilation of the *Ceylon Observer*

"All about Tobacco" which I would recommend everyone in any way interested in tobacco to invest in and carefully peruse its varied, reliable, valuable contents.

I studied my copy closely, on board the steamer on the homeward and outward journeys, and I may also say that when in London, in my search for books on the subject, I applied at some of the most likely publishing houses, as well as at the offices of *Tobacco* and the *Tobacco Trade Review*, two leading periodicals devoted to it, as their names imply, with the result that with the exception of these periodicals themselves I did not find a book that contained but a fractional part of its information. So much for Ceylon, its press and its enterprise. I brought it to the notice of tobacco brokers, who expressed interest in it, as also of an English gentleman, resident in Japan, whom I met at the "Sirocco" works, Belfast, on the outlook for a machine to dry his tobacco, which he said was not of very fine quality, not grown by himself but purchased from the natives.—Yours faithfully,
HUGH FRASER.

[We append the review referred to.—Ed. T. A.]

"ALL ABOUT TOBACCO."

A book bearing this title has been compiled by Messrs. A. M. & J. Ferguson, of the *Ceylon Observer* and *Tropical Agriculturist*, published at Colombo, Ceylon, and is to be obtained from the agents, Messrs. John Haddon & Co., Bouverie-street; and Messrs. Tribner & Co., Ludgate-hill, E.C. It is a careful and exhaustive compilation, and contains a vast amount of information, interesting primarily to all who grow tobacco or contemplate its cultivation. It is apparently intended for the use of agriculturists in Ceylon, but will be found of essential service to tobacco-growers all over the world. From first to last of its 330 pages of closely printed matter there is scarcely one page which will not afford valuable instruction to all concerned in the tobacco industry, and interesting information to the general reader. Being a compilation, and not an original work, it is not very easy to read or to digest, but this fault of its form is somewhat atoned for by a copious index, and the student will find pretty nearly all the known facts concerning tobacco scattered throughout its pages. The history, physiology, chemistry, culture, curing, packing, merchandise, manufacture, uses, and consumption of tobacco in all parts of the world are treated of by the best-known writers on the respective subjects, and we heartily commend the book to the notice of all interested in tobacco.—*Tobacco Trade Review*, Nov. 1st.

CACAO AND TOBACCO IN WATTEGAMA.

Dec. 6th.

DEAR SIR,—What say you to our getting over six cwt. of cacao per acre from Wattegama watte this year, five cwt. per acre already safe in five cwt. per acre last year and trees looking well for next year, I had several friends go over this land with me during the last three years, as I wanted them to notice that all surface soil was washed away, and when I told them what I would get in the way of crop soon, they simply laughed at me; oldest cacao only five years old; proof that a great deal depends on the proper cultivation.

On Mariawatte I have planted tobacco, I was told soil was not good enough and I was too late in planting. I am working quietly on with it, trying several ways and trust to prove that tobacco can be grown profitably in Ceylon (good leaf and colour).—Yours faithfully, J. HOLLOWAY.

PADDY (RICE) CULTIVATION: EXPERIMENTS IN THE KEGALLA DISTRICT.

Kegalla Kachcheri, Dec. 6th.

SIR,—I have much pleasure in forwarding for publication an interesting statement prepared at

my request by Mr. S. Weerackody Mudaliyar of this station, of a series of experiments conducted by him, in paddy cultivation, with the transplanting process.

2. Mr. Weerackody, it will be observed, owes the profitable results of his experiments to (1) intelligent cultivation, (2) the use of imported seed.

3. The experiments relate to the *Maha* harvest of 1887. The *Yala* harvest of 1888, the *Maha* harvest and the *Yala* harvest of 1889. The computed tax on the field is R5-50 per annum, and its sowing extent 4 bushels.

4. In 1887 the net profit on one harvest alone was R105-21 after deducting rent of field and tax. In 1888 the net profit on two harvests was R87-24½ after deducting rent of field and tax. In 1889 the net profit on one harvest was R83-64, rent of field and tax are not deducted as there is another harvest on the ground. In this year the crop was affected by *wandapidima* or barrenness.—I am, sir, your obedient servant,
H. WHITE, Asst. Govt. Agen.

Kegalla, Dec. 4th.

The Assistant Government Agent, Kegalla.

SIR,—I have the honor to inform you that I have brought to a termination some experiments on paddy cultivation, during the last four harvests commencing from the *Maha* of 1887. The field in which the experiments were made is one amunam or two acres in extent, bordering the Colombo-Kandy road in the east end of the town, and large numbers of villagers had the advantage of witnessing the different operations, and the growth of the crops. My object in making these experiments was to ascertain:—

1. The actual quantity of seed paddy required for transplanting.

2. The age and stage of growth of paddy plants that should be used for transplanting.

3. The proper distance for putting in the plants.

4. Whether it is practicable to have a successful *mavi* crop immediately following the *yala*, instead of a *bala vi* crop.

The sowing extent of the field is four bushels, and its highest yield for several years previous, was 16-fold or 64 bushels. I used only 2½ bushels of *sembala samba* for the nursery. The plants came up well, and after planting up the whole field, there were plants of about one bushel of seed remaining. These I distributed in six cart-loads, among four large land owners of this district, viz., Messrs. Molligoda, Herat, A. Perera and Dedigama Korala, and I am glad to say that they were equally successful as myself, although some plants were taken nine miles away and planted six days after they were rooted up. The yield of my field for this harvest was 104 bushels of clean paddy and about 8 bushels of empty seed. The latter was the result of excessive rain during the flowering season. If not for this abnormal state of weather the yield would have been far greater, and comparing the actual yield with the former best crops of this field it exceeded them by 40 bushels.

	R. c.
The expenditure for this harvest was:—	
2 men for clearing sides of the field, 2 days at 30 cents	1 20
5 pair buffaloes for 1st ploughing at 50 cents per pair	2 50
5 ploughmen and 1 attendant at 30 cents	1 80
20 men for digging up field with mam-motties	6 0
4 pair buffaloes for 2nd ploughing at 50 cents	2 0
4 ploughmen and 1 attendant at 30 cents	1 50
1 pair buffaloes for levelling nursery half-a-day	0 25
3 men for levelling and draining nursery half-a-day	0 45
1 man for sowing nursery half-a-day	0 15
Enclosing nursery, 2 men, 1 day at 30 cents	0 60
Enclosing the other portion of field, 2 men 3 days	1 80

2 pair buffaloes for levelling ..	1 0
4 men for levelling ..	1 20
5 women for roofing up and carrying plants	
5 days at 15 cents ..	3 75
12 women for transplanting, 6 days at 15 cents ..	10 80
30 men for reaping and carrying ears to threshing floor at 25 cents ..	7 50
5 buffaloes for threshing at 25 cents each..	1 25
5 men for attending to the threshing at 35 cents ..	1 50
1 boy for driving buffaloes..	0 25
2 men for winnowing half-a-day ..	0 30
Commutation tax ..	5 50
Rent for field ..	30 0
Pounding 104 bushels paddy at 19½ cents per bushel ..	19 24
1½ seed paddy ..	2 25
	<hr/>
	102 79
Value of 52 bushels rice at R4 per bushel..	208 0
Deduct expenses ..	102 79
	<hr/>
Profit ..	105 21

The second series of experiments were made during the yala of 1888. I obtained another variety of coast paddy, which I was given to understand, took only three months. The field was ploughed and the nursery was made as in the previous maha; but the seed paddy being bad, the plants did not come up well, and only one bed was planted up with plants obtained by thinning the nurseries when weeding. The crop on the whole was a failure though it entailed no loss, and it yielded only 15 bushels, and to make matters worse, the crop took 5½ months to ripen and this prevented that portion of the field from being prepared properly for the next crop.

The expenditure for this harvest was:—

2 men for clearing sides, 1 day at 30c	R. c.
4 pair buffaloes at 50c	2 00
4 ploughmen and 1 attendant	1 50
4 men for digging up nursery and 1 bed	1 20
1 pair buffaloes for levelling nursery half-day	25
3 men for levelling and draining nursery half day	45
1 man for sowing half day	15
2 men, 1 day for enclosing nursery	60
6 women for weeding rooting up and carrying plants at 15c	90
6 women for transplanting	90
6 men for reaping and carrying ears to threshing floor	1 80
4 buffaloes for threshing at 25c	1 00
4 men for attending to the threshing at 15c.	60
1 boy for driving buffaloes	12½
winnowing	25
for pounding 15 bushels paddy at 18½c	2 77½
value of 2 bushels seed paddy	3 00
	<hr/>
	18 10
value of 7½ bushels rice at R4	30 00
expenses	18 10
	<hr/>
profit	11 90

As the yala crop was on the land, I got the unoccupied portion of the field prepared and sowed ¾ of the whole field broadcast in the usual manner with two bushels of seed and I sowed two beds thickly with about one bushel of seed paddy to raise plants for the remaining one third, as soon as the yala crop was gathered that portion of the field was prepared, but on account of the severe drought that prevailed at the time, the plants could not be transplanted till they were nearly two months old, and although they grew well when transplanted they failed to throw out a sufficient number of shoots.

In January last these two plots were reaped parately and the results were 43 bushels from the

broadcasted ¾, and 40 bushels from the transplanted ¼ of the field. That is 21½ and 40 fold respectively. The expenditure for this harvest was:—

8 men for clearing sides of field 1 day at 30 cts.	R. c.	0 90
2 men for enclosing field 2 days at 30 cents		1 20
20 men for digging up field with mammoties		6 00
4 pair buffaloes at 50 cents 2nd ploughing		2 00
4 ploughmen and 1 attendant at 30 cents		1 50
6 men for levelling draining at 30 cents		1 80
10 women for 4 days for weeding ¾ field at 15 cts.		6 00
5 women for rooting up and carrying paddy plants 8 days		2 25
8 women for transplanting 3 days		3 60
24 men for reaping at 25 cents		6 00
2 sets of buffaloes at 15 cents		1 50
8 men for attending to threshing at 25 cents		2 00
2 boys for driving at 12½ cents		0 25
2 men for winnowing ½ day		0 30
commutation tax		5 50
rent		20 00
for bounding 83 bushels paddy at 18½ cents		15 35½
value of 3 bushels seed paddy		4 50
		<hr/>
	R90	65½
value of 41½ bushels rice at R4		166 00
expenses		90 65½
		<hr/>
profit	R75	34½

The fourth series of experiments were made during the last yala harvest. As the previous yala was a failure my object was again to see whether it was possible to have a ma vi crop immediately after the yala harvest. For this purpose I reserved 6 lahas extent or 1-7th of the field and sowed the remainder broadcast with three bushels of *hinati* paddy and as soon as that crop was reaped the six *laha* plot reserved was sown with *muttu samba*—a variety of mavi. In the mean time the reaped portion of the field was prepared, and when the plants in the nursery were five weeks old, they were transplanted throughout the whole field. The yield of paddy for this harvest was 66 bushels that is 22 fold.

The expenditure was:—

2 men for clearing sides of field 1 day at 30 cents	R. c.	0 60
4 pair buffaloes at 50c. per pair 1st		2 00
ploughing		...
20 men for digging up the field with mammoties		6 00
4 ploughmen and 1 attendant at 30 cents		1 50
3 pair buffaloes for 2nd ploughing at 50 cents		1 50
3 ploughmen and 1 attendant at 30 cents		1 20
3 pair buffaloes for levelling at 50 cents		1 50
6 men for levelling and draining at 30 cents		1 80
2 men for sowing		0 60
10 women for weeding three days at 15 cents		4 50
20 men for reaping at 25 cents		5 00
5 buffaloes for threshing at 25 cents		1 25
5 men for attending at threshing at 25 cents		1 25
1 boy for driving buffaloes		0 15
2 men for winnowing ½ day		0 30
Value of three bushels seed paddy at R1-50		4 50
For pounding 66 bushels paddy at 18½ cents		12 21
8 cart loads cowdung		2 50
		<hr/>
	R48	36
Value of 33 bushels rice at R4 per bushel..		132 00
Expenses		48 36
		<hr/>
Profit	R38	64

The last crop was attacked with the blight called *wandapidima* which was due to the ravages of a partly developed insect. As a great deal of the main stems of the plants were damaged by this pest, I got about eight

cartloads of rotten cowdung sprinkled throughout the field, and this manure assisted the plants to throw up new shoots, and in spite of this misfortune however, my crop was decidedly superior to those of my neighbours.

From these experiments, I have gathered that the proper quantity of seed paddy for transplanting (leaving a small margin for wastage) is one bushel per acre or two pelas of land.

That the proper age for transplanting *ma vi* (paddy of six months duration and upwards) is when the plants are four weeks old, and *bala vi* (paddy of five months duration and less.) When the plants are three weeks old and that the stage of growth of both should be, before the plants begin to throw out their lateral shoots, and I may state that the success of transplanting greatly depends on the strict adherence to this rule.

That the proper distance for transplanting is four inches. This, I have found out by planting at distances varying from three to six inches.

That it is quite practicable to have a *ma vi* crop after *yala*, and that this could be successfully done only transplanting be resorted to.

That transplanting is more advantageous than broadcasting, for many reasons.

1. That it will save at the very outset half the quantity of seed paddy at each harvest.

2. That it prevents the necessity of the tedious work of cultivating whole tracts of fields at once; as there is a long period of time to prepare the soil before and after the nurseries are made, and thus allowing both the cultivators and animals to rest after each operation.

That it enables the paddy plants to bear drought better as the plants have their roots two or three inches deep in the ground, instead of on the surface when broad casted.

That it materially increases the crops to such an extent as sometimes to double the ordinary yield of fields.

Considering the satisfactory water supply and the peculiar nature of the soil in this district, I am of opinion that every effort should be made to advance the transplanting system which I am glad to find is gradually being adopted in the villages about Rambukkana and a few other places.—I am, sir, your obedient servant,
(Signed) S. WEERACKODY.

TEA IN PERAK.—If only abundance of cheap labour can be procured, we suspect tea will be largely grown in the Malay Peninsula. We find an advertisement in the *Perak Gazette* to which we give gratuitous insertion because of its unique character:—

PERAK TEA.

One thousand pounds of Tea for Sale. Manufactured at the Government Tea Factory, Perak.

PRICES:

Quality, Unassorted, 65 cents (Mexican dollar,) or 3s sterling per lb delivered in Europe, Colonies or America. Quality, Pekoe Souchong, 60 cents (Mexican dollar,) or 2s 9d sterling per lb delivered in Europe, Colonies or America.

Higher qualities Tea, as well as Tea of Lower grade obtainable.

Tea packed in lead, in One or Two Pounds packets. A reduction in price on orders exceeding 20 pounds.

May be obtained of the following Agents—

TAMPING	...Moun Gee, Main Road
PENANG	...Messrs. Thean Chee & Co., Beach Street
SINGAPORE	...Messrs. John Little & Co.

Orders booked and further particulars supplied by

The SUPERINTENDENT, Government Plantations, The Hermitage, Perak, Straits Settlements.

COFFEE IN JAVA.—The report of the Royal Commission appointed for the purpose of inquiring into the Government coffee cultivation in Java has been published:—

“After a prolonged consideration the Commission arrived at the following conclusions:—1. To raise the price of coffee, to be paid to the natives, to f.20 per picul, and maintaining the compulsory delivery. 2. To decide in principle to abolish the compulsory cultivation, to be introduced five years after the announcement of the Bill to that effect. 3. To take preliminary measures during these five years in order to release the population, which is inclined to cultivate coffee, from heavy burdens, and to grant the liberty to planters of choosing the grounds, and the way in which they will work it. Further, that Section 56 of the Government regulations may be better applied. This relates to the cultivation in Java. For the west coast of Sumatra another regulation is proposed—viz., the increase of the price to f.25, and the maintenance of compulsory cultivation, but with the free choice with regard to the grounds, and the method of cultivation; and, further, the introduction of a poll-tax for the equivalent of the higher price. It is further proposed to abolish the present position of inspector of the coffee cultivation of Java, to commence recultivation of woods, and the establishment, if necessary, of Government undertakings, with payment of labour as an example and encouragement.—L. & C. Express.

COFFEE LEAF DISEASE IN JAVA.—Dr. W. Burck, the Assistant Director of the Government Botanical Gardens in Java, has for some years been engaged in experiments having for their object the mitigation if not prevention of the coffee leaf disease, *Hemileia vastatrix*; and he has published the results of his investigations in a pamphlet, a copy of which has reached us, entitled “Over de Koffiebladziekte en de Middelen om haar te Bestrijden” (“On the Coffee Leaf Disease and the Means of Combating it”). In the Introduction Dr. Burck warns the reader that he does not claim to have discovered a cure for the disease but only a means of mitigating its effects. The methods he recommends are the formation of high windbelts to prevent the spreading of the spores, and the treatment of the leaves with sulphuric acid and tobacco water, details of the processes being given, as also figures of the instruments used. The history of the fungus, a full description of its appearance, its effects in Java, &c. are fully dealt with. We hope that Dr. Burck may be ultimately successful in discovering a cure for the fell plague that has ruined the coffee industry of Ceylon, and threatens to do the same in Java.

LIBERIAN COFFEE, Bentota, Dec. 5th.—With reference to an inquiry in your paper of the 2nd instant by “E. K.” whether Liberian coffee plants can be grown by suckers the following information may be of use to him. About the year 1878 or early in 1879 I tried growing plants from the tops of the trees and tip ends of primary branches cutting them off with about half an inch of the matured or brown wood and setting them in shallow boxes with leaf mould and succeeded in raising about half a doz. plants from about a doz. cuttings put in; so I suppose suckers will answer about as well. I may, however, mention that these cuttings took a long time to grow, and as they resulted in only about 50 per cent of plants, I did not think it worth while continuing the experiment. Many years ago when quite a boy I remember being shown a fine piece of old *Coffea arabica* on Scalpa estate (now the Great Western of Dimbula) of about 20 to 25 acres supposed to have been grown from suckers. At the time I did not quite believe this and put it down to a cooly yarn to account for the fine appearance of the piece of old coffee surrounded by miserable looking and bugged trees. I wonder if any old planter in the island now can show any light in this. Weather exceedingly dry with cold mornings and dewy evenings. Tea flushing well and new clearings growing A. I. Snipe rather more plentiful than they were a few weeks ago and a good many Colombo folks have been down after them this year. Sundays are quite lively with the bang bangs one hears all day long in the fields and so we are not likely to have the railway opened till about March next. I wonder what is to prevent Government opening the line as far as Beruwalla in January. I hear Col. Clarke has been down inspecting the forests and there is likely to be a land sale soon chiefly small lots to suit natives.

PLANTING IN NETHERLANDS INDIA.

(From the *Straits Times*, Dec. 3rd.)

In Java the Government have set a plantation of gutta percha trees on foot in the Preanger district. Experience has shown that these trees thrive in West Java, and take kindly to both soil and climate:

Ministerial statements laid before the States General show that steps have been taken to mark out the boundary line of Netherlands territory in Borneo and New Guinea. It is intended to settle once for all the pending frontier difficulties with the British North Borneo Company.

A correspondent of the Batavia *Nieuwsblad* has seen for himself how matters stand in British North Borneo. He does not spare the B. N. B. Company's shortcomings, but admits that it has shown wonderful energy and vigour in administering the government of the country. The administration of justice, especially, meets with praise at his hands. Both employers and coolies on estates are closely looked after, and kept within the bounds of the law. He found among many officials a jealousy of Hollanders, owing to the latter having principally the management of estates there.

The example of encouraging enterprise set in B. N. Borneo has been followed in the neighbouring parts of the Netherlands possessions. The Resident of Amboyna has, for instance, gone to the Aru islands to farm out the pearl fisheries in that quarter on behalf of Government. Meanwhile, adventurers have had the run of them during the last 50 years without official interference. The Government have also become now more liberal in granting land to planters in the outlying islands.

The news of the Brazilian revolution sent the price of coffee up at Batavia, and brought about a brisk business in that article.

THE PROPOSED CINCHONA SYNDICATE.

In a letter to the *Chemist and Druggist*, Baron von Rosenberg gives the following information:—

Your smile at my idea that manufacturers and middlemen would be glad to help us is very gentle, but your compassion veils the evident desire to laugh out loud. I admit that my statement seems a remarkable one, but I will give you my reasons for it. Merchants and brokers are easily settled, for they get paid by a commission of 2½ per cent, which is of course more on bark fetching 6d than on bark fetching 3d. As to manufacturers, I submit that they are cutting their own throats by their present policy. In two years' time the amount of bark available for the market from Ceylon will be about half the amount put in during the past year—instead of 10 millions 5 millions. That decrease will not in any way be covered by the increase in shipments from Java and India. Now the manufacturers, trusting to a continuous or even increased supply, have, so as to keep the unit down, drawn heavily on the large stocks they themselves formerly held. These two causes of diminished supply will in two years, or even before then, send up the unit with leaps and bounds, and manufacturers will have to pay heavily for their present policy of keeping the unit unreasonably low.

Now one of the chief causes of this prospective reduction of supply is the low unit that has ruled during late years. Thousands of trees would of course have died in any case, but these have been increased to millions, and are increasing, by the impossibility of sufficient cultivation at low returns. The early age at which barking operations had to be commenced has also had a most pernicious effect in killing out enormous numbers of trees. Yet the barking had to be done to enable proprietors to keep their heads above water, their mature clearings not yielding them sufficient for this at the low unit, and further capital for a holding policy being unobtainable, on account of the

general distrust of a future in the bark trade. This distrust, and the fact that cinchona has lately been an almost unremunerative product, has also led many planters to cut out healthy cinchona to make away for some more paying cultivation, such as tea. There is, however, not only the actual decrease in quantity to be reckoned with, but also the decrease in quality, owing to cultivation being impossible. To give you an instance I had to semi-abandon two of my clearings so as to be able to thoroughly keep up the remainder. Weeds got the upper hand, forking I could not afford. Now cinchona is pre-eminently a surface-feeder, and in clean clearings the little feeder rootlets will be found outside the ground among the decaying leaves. Thus in a weedy clearing the food supply for the cinchona is materially diminished, and the health of the tree is injured by this as well as by the caking of the soil about the crown. The percentage of mortality in the above clearings has increased enormously from year to year and the percentage of quinine in their renewed bark has sunk from 8 per cent to 4 per cent. You may be certain that I do not stand alone in this experience, but that hundreds of my brother-planters have had to do the same with some of if not all their clearings. But you will say manufacturers and the retail trade will simply raise their prices if the price of bark rises. It is, however, not so easy to raise the price for the consuming public as it is to lower it, especially when it is known that the profits of the middlemen are, even at present, very great. But, should this be possible—should the manufacturers and the retail trade be able to raise their prices so as to obtain the same proportionate profits on a 6d unit as they do on a 12d one—then it would be well worth the consideration of producers to manufacture and sell their quinine on the co-operative principle, thus doing both themselves and the public a good turn. That this can be done, and without anything like an enormous capital being necessary, has been lately demonstrated at Darjeeling and Ootacamund. I do not, however, wish to press this point, which is not likely to become one of practical interest so long as manufacturers and the trade generally give us fair terms. What I am striving to secure is the co-operation of planters in one direction or another so that we may get our money's worth and not be driven like sheep. After eight years' residence and work on his estate a cinchona planter if he is lucky, gets 6 per cent on his money at the present unit, and runs the risk of seeing his capital float away altogether by mortgage or loss of trees. Why, in the name of all that is "shocking," should middlemen, between him and the public, make 30, 60, aye, in some cases, 90, per cent profit? Prices will, no doubt, rise of their own accord, but I wish to see planters strong enough to keep them at reasonable figure by union among themselves.

THE CEYLON TEA TRADE AND GROCERS' WRAPPERS.

A Ceylon estate proprietor now in England writes to us as follows by last mail:—

Since I have been at home I have noticed a good many Ceylon Tea Selling Companies using doubtful names such as "Mazawatte," "Patabala," "Arawatte" and "Santossie." These are trade marks and are properly registered probably. I have a suggestion to make and am prepared to use my best endeavours to carry out the scheme. It is this:—Collect a fund from all the estates in Ceylon to register as a design and print according to demand wrappers for grocers bearing on one side all the names of Ceylon estates (tea) and on the other in large type some short sentence calling attention to the merit of Ceylon (British-grown) tea. The Grocery Trade are always using such wrappers, and it appears to me my style is more sensible than a lot of doggerl verses or a picture of trees and scenery with a monkey skilfully concealed somewhere underneath: "Puzzle—find the monkey."

I do not know what my wrappers would cost, but the registration of designs &c. has been much reduced in price of late.

If this plan were resorted to the public would at any rate have an opportunity of finding out for themselves what constitutes a "trade mark" and what an estate mark or brand and I think genuine Ceylon tea would benefit. The subscription from each estate would be a small one, say £1 to begin with, and as advertising is of such very great importance in these days, this would be an advertisement and one which would bear the supposition of being self-supporting. The advertisement required to make known the idea would only be inserted in papers like the *Grocer*, *Grocers' Gazette* &c. for the Trade.

I trust you will make known the idea and obtain the opinion of practical people upon it. We trust to have the opinion of practical men on the above suggestion. Our fear would be that there would scarcely be room in any ordinary wrapper for the names of some 1,500 Ceylon tea plantations? and he would be a bold man who would write "finality" over the list of local tea estates.

WHY THE BRITISH PUBLIC SHOULD DRINK PURE CEYLON TEA:

(By a Planter.)

1. Because Ceylon tea is pure and China tea is impure.
2. Ceylon Tea is the best the world produces.
3. It is grown and manufactured by British subjects.
4. The Ceylon tea industry affords employment in ever increasing volume to thousands of British workmen in the manufacture of agricultural implements, tea machinery, steam engines; iron work for factory buildings, and in railway materials.
5. China uses no materials of English manufacture for the production of her teas, so that the consumption of China teas does not therefore assist British industries.
6. To increase the consumption of pure Ceylon tea is to improve England's trade in coal, iron, lead, railway materials, steam engines, machinery and agricultural implements in a large degree, and to a lesser extent in many minor industries. It also aids in supporting the growers who are sons of Great Britain and the natives of Ceylon who are subjects of Her Majesty. The profit made by the Ceylon grower is largely expended in Britain and British Colonies, while the profit made by the Chinaman is spent in his own country.
7. There are several millions of pounds sterling spent annually by consumers of China teas in Great Britain and her colonies to the great detriment of the interests of their own countrymen at home and abroad. Were this money expended on British-grown instead of on China-grown tea, a large proportion of it would come back to Great Britain to purchase necessities for the production of tea.
8. By drinking pure Ceylon tea you aid not only in giving material prosperity to a Crown Colony of the Empire, but you assist in the improvement of the Trade and Industries of Great Britain; you follow the good example set by Her Most Gracious Majesty Queen Victoria who drinks *Pure Ceylon Tea*—and who only lately graciously accepted a present of Ceylon tea sent her by the Planters' Association of Ceylon.

"INDIAN AND CEYLON INSECT PESTS."

In recurring to our notice of this little work, we may repeat that seldom if ever before have the forms of our insect pests been so accurately and clearly reproduced—the plates being on thick, toned paper, photo-etchings from the original pencil drawings, works of art popularly as well as scientifically. In this way the tea and sal pest with its parasites, the cardamom pest &c. are all given in Part I, and the price of the pamphlet of 76 pages with 4 pages of plates at R1.25 in Colombo is ridiculously cheap. Planters interested in fighting insect pests will find on one plate a represen-

tation of forcepump, and cyclone nozzles as worked for the spray of mixtures recommended to be used. To continue our review: a butterfly injurious to rice is described, but it does not appear to occur in Ceylon. Its scientific name is *Suastis gemias* (Fabricius). Next we have

A CEYLON CARDAMOM PEST (*Lampides elpis*, Godart.)
Plate I, fig. 5, a, male imago; fig. 5, b, larva; fig 5, c, cardamom capsules, two of which have been punctured by the larva,—all natural size.

Reports.—Two reports only have been received regarding this pest. The first report is contained in a pamphlet entitled "Notes on Cardamom Cultivation," by Mr. T. C. Owen (Colombo, A. M. and J. Ferguson, 1883), who notes—

"Of the enemies which attack cardamoms the most serious is an insect which bores a circular hole in the capsules and cleans out the inside; young plantations seem much more liable to this pest than older ones. In the former case as much as 80 to 90 per cent will sometimes be attacked and destroyed in this way; proximity to patana seems also the cause of increased liability to these attacks. Applications of wood-ash, lime or anything of a like nature, are said to be beneficial."

Mr. Owen failed to identify the insect which does the damage, and it has remained unknown till quite recently, when Mr. E. Ernest Green, of the Eton Estate, Panduloya, Ceylon, found a full-grown larva inside a capsule, and, on breeding it, found it to be *Lampides elpis*, Godart, a common butterfly of the Indo-Malayan region belonging to the family *Lycaenide*. The second report above referred to consists of a letter from Mr. Green, dated 21st November, 1888, addressed to Mr. E. C. Cotes, of the Indian Museum, Calcutta, enclosing drawings of the larva and cardamom fruit (reproduced on Plate I), and a letter to the writer, dated 23rd December, 1888. He writes—

"It is a curious thing that, although the damage caused by the larva of this insect is so general, it was only after a long time and much trouble that I caught the criminal red-handed. I had for some time suspected this pretty little butterfly, as it haunts the cardamom clearings in large numbers. Other planters seem to have been equally unsuccessful in determining the cause of the damage. My drawing was made from a single specimen found *in situ* in the cardamom capsule. I unfortunately neglected to make a drawing of the pupa. The larva was full-fed at the time [of capture], and pupated almost immediately upon the side of the box in which it was confined. Since then I have failed in obtaining other specimens. This is probably because the insects are all now on the wing; the larval state, no doubt, occurs earlier in the year during the growth of the young fruit. At the time of the cardamom harvest, when one's attention is more especially drawn to the damage, the insects have all vacated [the capsules], and are possibly lying as pupae amongst the shrivelled leaves and stalks. When the next fruiting season commences, I intend to make a very careful search for the eggs and larva, and, if successful, will send you a series for examination. I do not think the larva attracts ants, or I should have noticed the ants frequenting the cardamom stools. In drawing the larva I did not notice any secretive gland or retractile tentacles. As regards the food of *L. elpis*, its natural food-plant is, no doubt, one or more of the allied *Scitamineae*, which abound in all Ceylon jungles *Curcuma*, *Amomum*, &c."

With regard to Mr. Green's remarks about ants, they are in reply to my questions on the subject. Many larvae of the *Lycaenide*, including an allied species, *Lampides elianus*, Fabricius, have two retractile tentacles on the twelfth segment, and a gland on the dorsal line of the eleventh segment, which latter, at the will of the larva, gives off a sweet liquid, of which ants are extremely fond; in consequence of this many species of *Lycaenide*, which possess this gland, are most carefully tended and guarded by ants, who seem to make "cows" of them, much in the same way as they utilise *Aphide*, *Coccide*, &c. Mr. Green also notes that "Ordinarily from 5 to 10 per cent of the fruit capsules are perforated by this insect."

Zoological Position of the Insect.—This pest is a butterfly of the genus *Lampides*, of the family *Lycenide*, of the sub-order *Rhopalocera*, of the order *Lepidoptera*. The genus is a purely tropical and sub-tropical oriental one, and occurs almost throughout India, in Ceylon, in the Audaman and Nicobar Isles, in Burma and in the Malay Peninsula and Archipelago. The male butterfly is of a very beautiful, pale metallic azure-blue on the upper side, with a narrow black border to both wings; the hind wing has sometimes a series of black marginal spots, and there is always a short black white-tipped filamentous tail-like process to each hind wing near the anal angle. The female is pale dull (not metallic) bluish-white on the upper side, the outer black margins much broader, and the black spots on the margin of the hind wing considerably more prominent. The underside of both wings of both sexes is pale brownish, crossed by numerous more or less broken prominent white lines the expanse of the open wings is about an inch and a half.

Life History.—It is most certain that this butterfly at low elevations, flies all the year round, and that there are a constant succession of broods. The female probably lays her eggs on the flower buds of the cardamoms (*Elettaria cardamomum*), as is the case with another *Lycenid* (*Virachola isocrates*, Fabricius) whose larva lives on fruit. The young larva emerges from the egg within a very few days and commences to eat the flower bud or young fruit, burrowing into its centre for that purpose.

Mr. Green describes the larva when full-fed as "dull, pale green, tinged with red on dorsal area; three reddish narrow dorsal stripes; spiracles minute, black; head small, brown, retracted beneath the second segment; length .55 of an inch. Pupa smooth, pale dull yellowish-brown, marbled and spotted with dark brown, spots coalescing into three irregular dorsal stripes." An allied species, *L. alianus*, Fabricius, has been bred by the writer in Calcutta on the leaves of *Heynea trijuga*, Roxburgh, and in Java by Dr. Horsfield on *Butea frondosa*. It is most singular that two species of one genus should have such dissimilar habits. Only two other genera of Indian *Eycenide* are known to live on fruits, *Virachola* with two species, *Deudorix* with one.

Within the fruit all its larval state is passed; it grows with the fruit and lives on the fruit entirely, probably never venturing outside unless the fruit to which it has hitherto been attached should for any reason become unsuitable to it, when it would seek a fresh one, and immediately bore into its centre. When full-fed, Mr. Green surmises that it leaves the fruit, and turns to a pupa or chrysalis amongst the shrivelled leaves and stalks. This is contrary to my experience of the habits of *V. isocrates* and *V. perse*, which, in nature, usually pupate within the fruit on which they have lived. The pupal state would last but a few days probably, when the butterfly would appear, and the second cycle of life begin by the females laying a new batch of eggs. As the cardamom grows, as far as I know, in South India and Ceylon only, it is certain that it cannot be the legitimate food-plant of this butterfly throughout its great range. Mr. Green, however, appears to have been the first to breed the insect, and thus to discover at least one of its food-plants. It is probable, like other pests, that *L. elpis* feeds upon some jungle plant, but that, finding the cultivated cardamoms quite to its taste, it has taken to them and rapidly increased in numbers, owing to its new food-plant being provided for it in such great abundance.

Damage of the Pest.—Mr. Owen estimates the damage done by this pest to be sometimes as much as 80 to 90 per cent to young plantations. Mr. Green states that "ordinarily from 5 to 10 per cent of the fruit capsules are perforated by this insect."

Remedies.—Mr. Owen states that "applications of wood-ash, lime, or anything of a like nature are said to be beneficial." It should be remembered that Mr. Owen did not know what insect constituted the pest, or its life-history. I imagine his remedy is meant to be applied to the earth surrounding the plants, which might keep away slugs and worms, but would be absolutely useless in the case of this insect. The only remedy I can suggest is to catch and kill all the

butterflies that can be seen. Small boys, provided with butterfly nets, should be able to satisfactorily account for the greater number of butterflies frequenting a given area, to prevent the females laying their eggs being the object of the slaughter. The butterflies have a slow, flapping flight, and are very conspicuous, so their capture is very easy. Once the eggs are laid no further remedy is possible, I think. To prevent the increase of the butterfly it would be advantageous to hunt for, and collect, all the capsules with holes in them, and to destroy them by fire or burial. This search for affected fruits would, however, be very tedious and expensive, so I fear impracticable. To kill one gravid female butterfly, with perhaps two or three hundred eggs in her body, each egg representing the loss of a capsule, would be a much more effectual remedy.

Further notes on "the Wheat and Rice Weevil" are too long to be quoted; a notice of the sugar borer moth, *Diatrea saccharalis*, is interesting locally only because of the statement that about the year 1856 the insect did great damage to cane in Mauritius, into which island it was supposed to be introduced from Ceylon. The sorghum borer does not specially concern us in Ceylon, the larger millets being but scantily grown here.

GEMS AND GEMMING

occupy a good deal of local attention in connection with the two Syndicates already registered, and through the enterprise of private individuals who are exploiting on their own account. Our Sabaragamuwa correspondent reports the arrival of an expert in the person of Mr. Baddely connected with Mr. Siedle of Colombo. Mr. Harding, one of the promoters of the Company employing Mr. Barrington Brown, has arrived and is busy, the latter being due in a few days. For the second Syndicate registered in London which has to do with Southern India as well as Ceylon and with plumbago as well as gems, Mr. Wm. Gow has been collecting information and otherwise preparing the way for work. Several of the chief promoters of this Company have South African experience. Mr. Barrington Brown's report will be eagerly looked for.

TOBACCO AND MANURE.

The following extract is taken from *Nature* of August 29th. The British Consul at Bogota, in his last Report to the foreign Office on the agricultural condition of Colombia says that for tobacco cultivation in that country no manure is used, and the same land is used over and over again for an indefinite number of years. In some districts, where disease has completely exterminated the tobacco plantations, it has been found that when plants are brought from other districts they are not attacked for a few years, but ultimately they are also destroyed. This, perhaps, might be avoided by constantly importing fresh seed; but the experiment was tried on some of the best tobacco land in Colombia, with the result that as the seed brought from inferior districts began gradually to improve by transportation to the better soils, it became more liable to disease, while the plants grown from seeds brought from the better districts were attacked at once. Another instance of the ignorance of scientific agriculture in Colombia appears in the case of cocoa. It is most carelessly cultivated, though it is a crop which requires constant care and labour to weed and clean the ground, and free the trees of the numerous insects, especially the caterpillars, which infest them. A most destructive disease has lately attacked the trees in the south of the Tolima, which is one of the very richest districts in Colombia. This disease does not seem to have been investigated, and no remedy has been suggested, but the extent of its ravages will be understood from the fact that one of the plantations attacked produced only 175 pounds instead of 18,000 pounds of cocoa.—*British North Borneo Herald*.

VINE PESTS.

The following extract is taken from *Nature* of August 15th. The Agricultural Society of the Gironde, as quoted in a recent British Consular report, has published a statement shewing the average costs incurred last year by proprietors in this department in employing the best-known remedies, viz., (1) against the *Phylloxera*, sulphuretted carbon; (2) against mildew, the so-called *Bouillie Bodelaise*, a mixture of three pounds of sulphate of copper with one pound of slaked lime and twenty-two gallons of water; (3) against *Oidium*, sulphur; and (4) against *Antrachnosis*, a mixture of eighty pounds of sulphate of iron and 10 pounds of sulphate of copper. The total cost of using all these remedies is said to have amounted on an average to about 31s. per acre, an expense which cannot be called excessive, especially when it is added that their application served at the same time as a preventive against snails and slugs, which also often do much damage to vines.—*British North Borneo Herald*.

A FEW WORDS ABOUT OIL ENGINES.

To the Editor,

SIR,—I notice an article in your Thursday night's issue on the subject of oil engines. I saw Messrs. Priestly's Engine in London. It is nothing more or less than an ordinary gas engine, and the system on which it works is identical. The only difference is that you heat the oil until it gives forth a gas instead of drawing the gas ready made from the main.

The disadvantage of all gas engines, including Messrs. Priestly's oil engine, is that they can in the first place only be run at one speed, and secondly that they only give out the nominal horse-power and no more. For instance, a ten horse-power steam engine will easily produce fifteen to seventeen horse-power. A ten horse-power gas engine, however, will only produce ten horse, as a general rule a good deal under, unless all the valves are specially clean and the pressure of gas a good one. Practically, therefore, to work a gas engine you want one of about double the nominal power of the steam engine you already have in your factory. This is the more necessary as in the ordinary patterns, such as the "Otto," the explosion occurs only every second revolution, and any sudden strain is therefore more likely to put the machine out of gear.

With regard to the speed, there is one make (Messrs. Atkinson Sons' patent) where the speed can be varied at will, and in which the explosion occurs at every revolution. There is also a method of manufacturing gas to use with this machine where none is available in the ordinary way. The chief point, however, as regards the utility of the machines for tea factories is the cost. A 20-horse gas would cost between two to three times as much as a 10-horse steam-engine with a 12-horse boiler. What we really require is some system of using oil to heat an ordinary steam boiler, and I believe that experiments are being carried on in this direction.

If a method is discovered, it would be applicable to heating Siroccos and other firing machines as well as boilers, and one difficulty as regards the future of Dimbulla and adjoining districts would be solved.

MACHINIST.

Colombo, December 13th.

—Local "Times."

THE QUALITY OF COCONUT OIL.

Manufacturers of Ceylon coconut oil are making an investigation at this late day of the comparative quality of the two grades of coconut oil which are made in Ceylon and Cochin, with the view of ascertaining why the latter is considered superior and commands a higher price than its rival. The parties making the inquiry had previously arrived at the conclusion that the difference in quality was due to the soil of the two localities where the coconut trees are cultivated, but a geologist made it appear that such a theory was absurd and they directed attention to the methods

employed in drying the nuts. We see it announced that the difference in quality is now attributed to the fact that the whole fruit is subjected to artificial heat for three months in Cochin, while in Ceylon the nuts are split in half and sun dried. Dealers in the article on the other side claim that Cochin oil is richer in stearine, while operators in Ceylon oil exclusively are disposed to question the legitimacy of the distinction which they think is partly due to commercial "jugglery." In this market the credit is given to an improved process of manufacture, but if that were the true cause of the superior quality of Cochin oil, there would be no excuse for the low grade of coconut oil made in England and on the Pacific coast where the manufacturers enjoy much better facilities for their business and are in a position to learn the latest improvements before they are introduced in the far East. However, the last argument has been demonstrated as a fact by practical experience. The finest coconut oil ever seen in any market has been made in this State from refuse material in desiccated coconut factories, by a process not known outside of the United States, and if the coconut growing countries were nearer home, there would be no necessity for importing the oils. Owing to the cost of transporting the nuts, the American oil industry can never reach large proportions, as it is confined to the utilization of a by-product. If the Ceylon people would carry out their experiments in the direction of employing an improved process in manufacturing, they may be successful in meeting competition both in quality and price. They will have to depart from old-time customs and communicate with the new world in regard to the latest contrivances, instead of relying so much on "coolie" labor to accomplish the desired results.—*Oil, Paint and Drug Reporter*.

A NEW SHADE TREE FOR CACAO.

The extensive injury done to the Bois Immortel in the Cacaguals of the mainland by locusts about three years ago compelled the planters to seek for a shade-tree that would not be exposed to their ravages. The Cacagueros of the district behind Yrapa have discovered in the *Apamato*, a native tree of the neighbouring forests, one which they think to be better for their purpose in many ways than the time-honoured *Erythrinus*. Its wood is stronger, in stem and branch; the foliage is thicker, and the long and darker leaf is persistent, not dropping from the tree in the dry season, thus protecting the Cacao trees throughout the year; and the branches, which are not formed or do not spread widely till the tree has shot up to a considerable height, are stiff and not liable to be broken by high winds. Locusts do not attack this class of leaf. Specimens of the young plant have been sent for, to the Main, by my informant, Mr. Pedro Ducharme, of this town, as well as, if procurable just now, the flower and fruit or seed, in order to trace its botanical affinities.

The tree is said to attain about the same bulk of stem and height as the B. Immortel, with a spread at top of about 45 or 50 feet. The Cacao-planters of the Yrapa district are replacing their *Anaucos* and *Bucares* by the new tree as fast as they can.

Stronger, closer fibre indicates slower growth, and it seems likely that even if the *Apamato* when full-grown offers a shade better for Cacao than the Immortel, it must be supplemented in young plantations by a more rapidly-growing tree till the new plant, having shot up and made its spreading head, the temporary and provisional shall be removed.

As Mr. Ducharme does not speak from personal experience or knowledge of the *Apamato*, and so many proposed alternatives for the old *madre del cacao* have failed to dethrone her, it is as well to reserve opinions till more exact information be received. The thanks of Cacao-growers are meanwhile due to Mr. Ducharme for what may prove to be a hint of some value to them.

8th August, 1889.

T. W. O.

P.S.—Later in the day I met a friend from Maturin, who, on being asked, said the tree was well known to him. According to him, it is a very tall tree, branching

only at top, otherwise somewhat resembling our *Cyppe* has not large leaves, nor is umbrageous; flower greenish or greenish yellow, bell-shaped, approaching the tulip in form, but smaller, or perhaps resembling Pou; the fruit, somewhat drupe (or plum-like?), resembling a small Mango, but is dry and inedible. The flowers grow in clusters—also the succeeding fruit. The wood, he adds, is like a coarse-grained *Cyppe* (*Cordia gerascanthus*), and in scent it also differs little from that wood.—T. W. O.—*Agricultural Record*.

COCONUT AND CINNAMON.

I do not remember one year since I took to planting in which we had better weather for vegetation than during the expired portion of this year. We escaped the much dreaded drought at the beginning of the year with 1'26 inches of rain in January and '04 in February. It was a very mild drought, and it was as well that it was mild, otherwise sceptics, and those who now can afford to pooh-poo Coconut leaf disease and question whether it is a disease at all would have piped a different tune. The very favourable weather we have had from March onwards has enabled Coconut trees, or rather plants, for it is these that were most affected, not to shew any visible signs of having suffered any permanent injury from the inability of their leaves to properly perform their allotted functions. Whether the badly affected plants have suffered permanently or not time will shew by their susceptibility to repeated attacks. Last year the disease developed with the North-East rains and attracted attention in January this year. Three years ago I find a correspondent to the *Observer* speaks of a "blight" affecting the branches of Coconut trees. Could that and the present affection be identical I wonder, and could it have been slowly but surely establishing itself more firmly every year owing to Coconut Planters lulling themselves into a state of inaction with the belief that of all cultivated products the coconuts tree is to be the only one to enjoy a perfect immunity from insect or parasitic attack? May experience strengthen their very comforting belief! June was a comparatively rainless month with only 2'09 inches of rain, but July and August have been simply splendid months for growing. And yet, in spite of such a favourable year when vegetation should be looking its best, the senior Editor of the *Observer* records in his notes of a visit to Henaratgoda that coconut trees are looking "fairly well." Such has been the result of my observation too, and I remarked this to a leading Sinhalese gentleman very largely interested in coconuts, and whose buoyancy is proverbial. He said that the late Mr. David Wilson once attempted to frighten him into the belief that coconuts were doomed, and had failed.

The rain we had on Sunday, Monday and Tuesday mornings will greatly aid in speedily maturing the bud now on the Cinnamon bushes, and will make peeling easy again.—Local "Examiner."

FORESTS OF VANCOUVER'S ISLAND.

The forests of the mountains in the interior of Vancouver's Island differ materially from those of the lowgrounds near the coast, while as one when travels inland the Douglas Fir (*Pseudotsuga taxifolia*) is the chief tree until an elevation of about 800 feet is reached. It then becomes insensibly intermixed with the western white pine (*Pinus monticola*), and a sprinkling of Red Cedar (*Thuja gigantea*). Within a few miles of Departure Bay, where all steamers bound for Alaska take in coal, rises Mount Benson, attaining the height of 3,360 feet, at about eight miles in a direct line from the coast. The lower slopes of this mountain are covered with Douglas Fir of enormous size, many of the trees being nearly 300 feet high and over 3 feet in diameter. The chief undergrowth is the Bracken (*Pteris aquilina* var. *lanuginosa*), which is generally from 4 to 6 feet high, and so interlaced that to force one's way through it, without first tearing it apart with the hands, is impossible. After this is passed, the under growth is composed of Sala

(*Gaultheria Shallon*), which is, if anything, more difficult to get through. Amongst the Sala the trees stand closer together, and are much less in diameter, but tower straight as arrows to an immense height. Here the Pine becomes quite frequent, and the Sala more interesting, for, in great profusion, the rare *Boschniakia Hookeri* is growing as a parasite upon its roots.

Then, as one ascends still higher, the western Hemlock (*Tsuga Mertensiana*) comes in, and our forest is composed of four species. Gradually the trees grow less in size, until, as the summit is neared, they become stunted, but still healthy and vigorous. On the summit two species appear, as if they were new creations. These are *Tsuga Pattoniana* and *Abies amabilis*.

Later explorations on other mountains showed the same trees kept their relative position, but toward the north were found at a decreasing altitude. It was ascertained that the forest trees of one mountain were those of another, and that *Tsuga Pattoniana* and *Abies amabilis* were the rule, and not the exception, as they were in company on every mountain, and were the last to disappear at an altitude of about 5,500 feet. Above this very few trees are found, but it was quite evident that their absence is not caused so much by cold as by the immense snowfall of the moist winter, which leaves the mountain summits covered to a great depth in the spring. Close to snow of unknown depth, trees, with a diameter of 2 feet, are growing vigorously on Mount Arrowsmith, while above them all is snow, or depauperated and broken trees, flattened down by the snow, growing while they can, and lying dormant the remainder of the year.

Without exception, the forests of Vancouver's Island are the finest now in Canada. It is sad to think that these noble forests are being devastated year after year by fires started by men who are "improving" the land, and what it is impossible to do with the axe is being done with fire. In every part of the island the timber is sound, and fit for market, and it might be kept so but for the recklessness of irresponsible men. For every tree destroyed by the axe, a thousand are being destroyed by fire, and year by year the number is increasing. During the last half of July and August, and early September (1887), the whole country was enveloped in smoke, and fire met the traveller at every point. A few years more and these noble forests will be but the blackened remains of a glorious heritage, as every year increases the power of the fire, and gives it more prepared fuel for the next season. It is not alone on Vancouver's Island that this destruction is going on.

The Olympian Mountains, on the other side of Puget Sound, in Washington, are being denuded in precisely the same way; and this autumn (1889) over nearly the whole of British Columbia and northern Washington, the sky was obscured for six weeks by the dense smoke of the forest fires raging in all parts of the country.—JOHN MACOUN, Ottawa, in "*Garden and Forest*."

DIRECT INFLUENCE OF POLLEN ON THE ORANGE.

Having read with great interest Mr. Phelps' valuable article on the direct influence of pollen on the Orange in a recent number of the *Gardeners' Chronicle*, I should like to ask him for a little further information on this subject, which would make the matter clearer to one unlearned in Oranges. I should be very glad if he would state what are the distinctive characters of the cellular pulp, flavour and shape of Navel Oranges, which distinguish them from the two kinds of Blood Orange which he mentions as having been affected directly by the pollen of the Navel variety; one might then judge better from his description of the fruits how far the Navel character appeared in the fruits borne by the Blood Orange trees. Also one would like to know the characters of the Majorca and Ribbed du Roi Orange which he mentions, and to what classes of Orange they belong. Further, am I right in judging from Mr. Phelps' re-

marks on the sterility of the Blood Oranges bearing the Navel marks that he considers this sterility due in some way to the direct influence of pollen having occurred? From what he says further on in his article on the character of the seeds of the Navel Bahia Orange when influenced by the pollen of the St. Michael's variety, one would infer that seedlessness does not always occur in fruits which show the direct influence of pollen. It would be very interesting to know how far it is usual to find sterility accompanying the direct influence of pollen on the fruit. In the account given by Maximowicz and others of this phenomenon, I do not remember any mention of sterility appearing in the fruits described by them. It is possible that those fruits which, through cultivation or other causes, have become more or less sterile, such as Gourds, Cucumbers, &c., may be those which are most easily influenced directly by pollen; for, according to Mr. Phelps, the Imperial Blood or Maltese Blood usually only produce one or two seeds. It would also be very valuable to know whether Mr. Phelps or other observers have ever noticed any after-effect on the mother after the direct influence of pollen on the fruit has occurred; i.e. whether a tree which has once had its fruits directly influenced by pollen has ever been known to produce more anomalous fruits without again receiving the pollen of the variety or species which affected it before. Mr. Burbidge, in his book on *Cultivated Plants*, quotes an instance of a white Calceolaria plant producing red flowers on a branch on which some flowers had been crossed with pollen from a red variety; and these red flowers were not merely those which had been crossed with the foreign pollen. It is possible that Mr. Phelps or others who have studied this interesting subject, might be able to add some more instances to the few already known of this further influence of pollen on the mother plant.—A. B.—*Gardeners' Chronicle*.

THE SO-CALLED MUSSËNDA COFFEE OF REUNION.*

[Communication from the Research Laboratory of the Pharmaceutical Society.]

BY PROFESSOR W. R. DUNSTAN.

A short time ago, Mr. Thiselton Dyer, the Director of Kew Gardens, suggested to me the desirability of making a chemical examination of a supposed substitute for coffee, concerning which a good deal has of late been heard in France. It has been stated, on the authority of M. Lapeyrère, a pharmacist residing in the island of Réunion, that the seeds of a plant abundant in the island which he calls *Mussenda boronica*, known to the natives as "wild orange," closely resemble coffee berries, not only in appearance, but also in their chemical constituents, so that they may be regarded as a formidable rival to coffee. This announcement appears to have caused some scare in the coffee trade, and it is said that many inquiries for the seeds have been made. M. Lapeyrère's paper on the subject is printed in the *Bulletin Bimensuel de la Société Nationale d'Acclimatation de France* for 1888, pp. 285-300. It contains an account of the botanical characters of the plant, which are stated to differ from those of the known representatives of *Mussenda*, and the plant is therefore adjudged by M. Lapeyrère to be a new species. The results of a chemical analysis of the unroasted seeds are recorded, from which it appears that they contain from 0.3 to 0.5 per cent. of caffeine.

An examination of the seeds at Kew revealed the fact that the plant in question is really a member of the natural order *Loganiaceæ*, named *Gartnera vaginata*, and not a new species of *Mussenda*, which belongs to the *Rubiaceæ*. In a despatch to the Foreign Office, Mr. St. John, the British Consul in Réunion, corrects some misstatements regarding the plant which have been made in connection with its proposed em-

ployment as a substitute for coffee. Mr. St. John points out that the shrub is not plentiful in the island, that it yields fewer berries than the coffee shrub the fruit growing only at the end of the branches. He further asserts that the *Gartnera* seeds are less fragrant than coffee, and would probably be more expensive.

These facts do not, however, affect the interest and importance attaching to the discovery of a new source of caffeine, and a possible substitute for coffee. M. Lapeyrère's statement that the seeds contain caffeine is not so remarkable when made in reference to a plant belonging to the natural order *Rubiaceæ*. In view, however, of the fact brought to light at Kew that the plant belongs to an entirely different natural order, *Loganiaceæ*, the statement becomes not only remarkable but improbable. A special search was therefore made, not only for caffeine but also for theobromine and other compounds belonging to the same family. In the first instance 150 grains of the very hard seeds were powdered, mixed with half their weight of magnesia, and made into a paste with water. This paste was dried and reduced to powder. Having been packed in a continuous extraction apparatus the powder, which would not contain caffeine in the free state, was successively exhausted with boiling chloroform, boiling alcohol, and finally, with boiling water. The residues left by the evaporation of these solvents were examined for caffeine. The residue left by the evaporation of the chloroform, consisting largely of fat and resin, was extracted with dilute hydrochloric acid, and the acid liquid was tested with a solution of iodine and with Mayer's solution, in both cases with a negative result. Another part of the same liquid was oxidized with nitric acid, and the residue mixed first with a little ammonia and then with potash, but neither a red nor a violet coloration was observed, so that caffeine and theobromine were certainly absent. The alcoholic and aqueous residues were similarly dealt with, but here, again, no trace of caffeine or of any similar substance could be detected. Since a plant belonging to the *Loganiaceæ* might be expected to contain strychnine or brucine, each residue was tested for these alkaloids, but neither was found. In fact, at no stage of the inquiry was there found any evidence of the existence of an alkaloid in these seeds. Unless, indeed, there is included the doubtful indications, afforded by the alcoholic residue of the presence of choline or of a substance resembling it. The seeds contain, besides much proteid and a small quantity of sugar, a fat which seems to be similar in some respects to the fat contained in *Strychnos Nuxvomica*, but owing to our supply of the *Gartnera* seeds having failed, it could not be examined minutely. It must be remarked, in conclusion, that the seeds bear only a slight superficial resemblance to coffee berries. They are flatter and are further distinguished by carrying on both surfaces a series of deeply marked radiating lines.

It had been intended to publish the facts in reference to the botanical nature of "*Mussenda* coffee," in the first instance in the November number of the *Bulletin* of information which is issued by the Kew Department. The notice was, however, crowded out of this publication at the last moment, and under these circumstances Mr. Thiselton Dyer generously placed at my disposal, for the purpose of this communication, the information which will now subsequently appear in the December number of the *Kew Bulletin*.

The paper gave rise to the following discussion:—

The PRESIDENT said this paper was rather unsatisfactory for the purpose of discussion, the results being purely negative, but such results involved a considerable amount of labour and skill, and if anyone would like to ask for further information Prof. Dunstan would be happy to afford it. It was perhaps one of the advantages of a Research Laboratory that substances of this kind, which were stated to have properties of great commercial value, could be quickly examined and the results promptly published.

* Read before the Pharmaceutical Society of Great Britain, at an Evening Meeting in London, Wednesday, November 13.

Mr. HOLMES said it might appear rather curious at first sight that a French pharmacist should mistake a member of the natural order Loganiaceæ for one of the Rubiaceæ, but this mistake had plainly arisen from want of good knowledge of systematic botany, which he was afraid had been rather neglected of late years, in comparison with morphology and biology. The real point of distinction between the two orders was that in the Rubiaceæ the ovary was inferior, while in the Loganiaceæ it was superior. M. Lapeyrère, in his communication published in the *Bulletin de la Société d'Acclimatation*, had figured the ovary of his *Mussaenda borbonica* as superior, which showed that he did not understand that the genus *Mussaenda*, as belonging to the Rubiaceæ, should have an inferior ovary. The *Gartnera vaginata* bore a strong resemblance in texture and shape of the leaves and in colour and arrangement of the flowers to *Mussaenda*; but in the latter genus the seeds are minute, whilst in the plant figured by M. Lapeyrère they were large and only one in each cell of the ovary. The opposite character of the leaves and the presence of interpetiolar stipules in both natural orders might also have further misled him. The mistake made by M. Lapeyrère was one therefore that might easily arise in the absence of good books of reference or of an imperfect practical knowledge of botany.

Mr. GREENISH asked if these berries had been treated in a similar way to coffee, roasted and ground, and, if so, did they yield a substance which would be at all suitable as a substitute for Coffee.

Mr. CHRISTY said there were plenty of very excellent substitutes for coffee, but as the law now stood they could not be used as coffee. And drink made from a new seed must be called by a new name, and that was what the public would not accept. If this were introduced, although it might have the taste and smell of coffee, if it were declared by the Pharmaceutical Society not to be coffee, it could not be sold as such.

Mr. LOMAS thought it rather strange that this French chemist should state that the berries contained caffeine if they absolutely contained none.

Professor DUNSTAN said they were stated to contain caffeine, and were put forward on that ground. Mr. St. John, the British Consul, tried them, and said they were much less fragrant than coffee. They seemed to present no advantage over ground date stones and coffee substitutes.

The PRESIDENT remarked that probably all berries when roasted were more or less aromatic. He must say he sympathized with the public on this question; he believed in coffee, and did not believe in any of the things which were substituted for it. He also believed in the physiological action of coffee, and could tell what it was without analysis. There was no doubt it was advantageous that the public taste should gravitate towards good things, and in the case of coffee, until a few years ago English people, as a rule, knew nothing about it. That which was sold as coffee was a mixture which was not coffee, but he would not say what it was. Those who had once enjoyed the luxury of real coffee, properly made, would naturally rebel against having anything substituted for it. He concluded by proposing a vote of thanks to Professor Dunstan, which was carried unanimously.—*Pharmaceutical Journal*.

COFFEE AND CINCHONA IN JAVA.

The East Java Agricultural Company has held its annual meeting, at which the report of the preceding year was presented. It is a satisfactory statement. Of the coffee undertaking Sirah Tapah only 100 of the 439 bouws have been worked, in consequence of the unfavourable weather. The crop of Kali-Padang will be small, but on the average a sufficient crop may be expected for 1889. The expectations of the 1888 crop have been realised, and the quantity amounted to 6,350 piculs of coffee. The cultivation of the Cinchona undertaking Soekasarie amounted to 633,000 trees, which number has been increased by 57,000 grafts as well as by 10,000 succirubras. From

the second cultivation about 15,170 Amsterdam pounds of Cinchona bark were obtained, of which 9,414 Amsterdam were shipped. The shipping and working charges may be estimated at c. 12 to c. 15 per Amsterdam pounds when shipped by sailing vessels, so that bark of 3 per cent. will not give profit in the event of the unit declining to c. 6, and, moreover, the charges for managing the undertaking have still to be taken into account. The production of coffee compared with the former year was much better, being 6,375 piculs, which were sold at an average price of c. 51 55-100, which proves the good quality of the coffee. Of the bonded loan f. 6,000 can be redeemed, and the debt is thus reduced by f. 10,000; f. 10,500. The dividend was fixed at 12½ per cent., or f. 125 per share of f. 1,000, of which already 50 guilders have been paid.—*London and China Express*.

"THE TROPICAL AGRICULTURIST."*

This Journal has been strongly recommended to the Local Agricultural Boards and others as the best current periodical treating of Tropical Agriculture, and anyone may satisfy himself of the wisdom of this advice by referring to the very complete Index published in the June number (to be found in the Public Library); this number completes the Eight Volume, and it will have to be confessed that its scope is quite encyclopedic, its contributors practical and accurate, and in every way it might serve as a model of what could be done in "Trinidad," if every one would take the excellent advice given by Mr. Hart in his second Lecture, "Our work," and pull together for the common good.

Reviewing the last three numbers from a West Indian point of view, there is much in which we have a common interest with our Cingalese brethren, but, many of their leading staples being foreign to us and occupying considerable space, the pages devoted thereto would probably be turned over unread, but even in these pages there are lessons for us to learn, viz. :—

TEA.—This is perhaps their leading staple, but one that is out of the question in Trinidad; it has supplemented Coffee in Ceylon on many estates, the one having been cut down to make room for the other, much in the same way that we once cut down cane to plant cocoa. The manner in which this product has been established on the failure of Coffee (due to the fatal leaf disease) should prove a valuable lesson to our half-hearted planters. Another notable fact is the marvellous way in which they canvas, advertise and push the sales of this product in all the markets of the world. Thus we have the Ceylon Tea-planters' Association everywhere to the front in London, and the Ceylon-American and Ceylon-Australian Association to force the product into notice in each country. Is it quite hopeless to suggest a similar policy here with regard to Cocoa? Could agents do nothing for us in England and America, and will alarmists as to the future of Cocoa admit what is said in the Ceylon Journal, "that there is ample room in the world for all the Coffee, Tea and Cocoa that can be produced"—the population increase faster than production, and these staples must be properly regarded as necessities rather than luxuries.

COFFEE.—The main interest under this head is in the fact that its cultivation is being rapidly abandoned in Ceylon as well as in the Java, and perhaps that helps to explain the present favorable price of the article and at the same time opens the field to us. In Ceylon they are now coming to the conclusion at which we had arrived long ago—that coffee can be grown with great advantage at the sea level. There the soil is mostly poor and it must be heavily manured; but with our rich vegas we might look forward to a production that would be astounding to the Ceylon planter. In Ceylon also the system of shipping in the parchment is in favour, and that should be a great en-

* "The Tropical Agriculturist"—A. M. & J. Ferguson, Colombo, Ceylon; London Agents, John Had- don & Co.

couragement to us, as we have no elaborate cleaning machinery as at Colombo, and it must simplify matters very much.

COCOA.—About this staple very little is said, although we very well know that in this pushing Colony they make the *very best* of what they have, but their soil is not favorable, and therefore they do not much extend it.

COCONUT.—This is the oldest if not the most important of their staples, and naturally meets with a great deal of consideration. They have lately arrived at the conviction that coconuts can be profitably planted in the inland districts and even at altitudes from 1,000 to 2,000 feet, and still more surprising to us, we learn that they do not hesitate to plant them in stiff clays lands; only, in that case, they take care to pulverise the soil by digging and turning it over to a depth of 18 inches. The principal controversy just now in Ceylon, in connection with coconuts, is the use of salt. The consensus of opinion is in favor of it, either placed round the roots, *i.e.*, the stem of the tree, or in holes when planting out, but not so much as an application to the fronds and spathes as we use it. Salt is by them hardly regarded as a manure, although elsewhere it is at least considered to have a stimulant action, *i.e.*, it acts chemically in decomposing otherwise inert matter and liberating nitrogen, etc., which would benefit the plant. Salt is, moreover, thought to stand high as a destroyer of insect life, and more particularly, the Termites or white ants. These pests are very destructive with us as well as in Ceylon, and would very soon account for cocoa or fruit trees if unmolested. The question is much mooted in India as to whether they ever attack living trees; this point may be very easily settled by any observer in breaking down their tracks, when it will be seen that they eat away the living bark as they go, and this in time leads to the death of the tree. As to salt being a preventative it is at least doubtful, because they are not affected by immersion in a saturated solution. To the lower forms of life fungi, etc., salt, no doubt, is fatal.

BLACK PEPPER.—This would be regarded with us as a minor industry of, at most, the third order: but in the East it is esteemed as a paying article and a cultivation that gives a speedy return and requires but little skill. It might be grown here on the Bois Canon. In Ceylon it is recommended to plant it *without* shade and trimmed down to low bushes as in viticulture. It requires very good land and would eminently suit coolies or other small cultivators. Could not some of the District Agricultural Boards undertake to supply plants with the fullest instructions to any willing small proprietors? say in the rich quarter of Siparia! His Honour Sir John Gorrie, who always speaks to the purpose, said that it is to these small men we must look to help us out in the establishment of new industries! Is it not even possible that some of our East Indians are already familiar with the cultivation?—*Agricultural Record*.

COTTON EXPERIMENTS.

(From the Proceedings of the Agricultural and Horticultural Society of India.)

From Mr. J. Cameron of Bangalore, asking if any cotton seed could be supplied to him. Mr. Cameron is engaged in cultivating cottons experimentally for the Mysore Government, the object being to ascertain which variety is most likely to repay growers there. 2½ lb. of Sea Island and New Orleans seed were supplied, and it was suggested that the seeds of the different cottons commercially recognised in Calcutta should be obtained; the offer was accepted with thanks by Mr. Cameron. Mr. D. McL. Morrison has kindly given a list of the cottons known in the Calcutta markets *viz.*, Bengal, Cawnpore, Ferozabad, Indore, Agru, Delhi, Hatras, Kurjsh. Bombay and Madras cottons are also sub-divided in a similar manner in Mr. Morrison's list. Correspondents residing in the parts of the country, by the names of which the

varieties are distinguished, have been asked to cooperate in procuring seed. In response, Mr. J. Gasper Nicholls, writes from Cawnpore:—"I asked Mr. Wishart (Messrs. Begg Sutherland & Co.,) who is Secretary to our Chamber of Commerce, about seed of the Cawnpore staple cotton. He tells me that there are three distinct varieties, the Gángápári, *i.e.*, that grown in the western districts of Oudh, namely, Hardoi, Oonao and Rai Barielly; the Jamnapari grown in Hamirpore, Banda and Jaloun (Kalpi and Koonch) districts; and the 'Desi,' or common country cotton of the lower Doab—the tract between the Ganges and the Jumna. Possibly the Kalpi cotton is a hybrid, for the Company Bahadour spent much money and some lives about 50 years ago in trying to introduce American seed at Kalpi." Mr. Nicholls continues that Mr. Wishart has very kindly promised to meet the Society's wishes.

In connection with the attempt to introduce American cotton at Kalpi, alluded to by Mr. Nicholls, which was under the superintendence of professional American cotton planters, it may be stated that a much later attempt made by the Society in Lohardugga district has also left its mark. Mr. Basu of the Agricultural Department says of the cotton now cultivated in that locality, that the plant has the appearance of American cotton, and the fibre is longer and superior in other respects to the country kind.

FISH-CURING OPERATIONS IN MADRAS.

It is satisfactory to note that during the year 1888-89 fish-curing operations in the Madras Presidency show a decided improvement, and that it has continued to do so year after year with very slight variations towards a decrease. The number of yards where they were carried on at the close of 1887-88 was 148. During the period under notice 3 were newly opened and 2 closed. Thus 149 yards were open at the end of 1888-89. The total weight of fish brought to be cured was 1,132,756 maunds or 41,611 tons against 1,020,686 maunds or 37,495 tons in the previous year, showing an increase of 4,116 tons or over ten per cent. Two causes account for this favourable result, one was the general development of the industry, and the other the genial character of the season. The total quantity has doubled in the last five years, *i.e.*, from 20,108 tons in 1884-85 to 41,611 tons in 1888-89. Last year the quantity and value of salted fish exported from the Madras Presidency were 2,921 tons and R5,57,360, respectively. The bulk of the exports go to Ceylon; considerable quantities also go to Bombay, and there is some export to Burmah. It is stated that since 1883-84, the year in which the success of the fish-curing industry may be said to have been established by the breaking up of the combination among the fishermen in South Canara, the value of the exports has steadily increased from R2,64,039 to R5,57,360, though the quantities have shown some slight fluctuations. There is also a steady improvement in the quality of the article exported, as the average value per lb of salted fish rose from 9 pies in 1879-80 to 1 anna 4 pies in 1888-89. The average quantity of salt issued to each maund of fish cured was 12 55 lb against 12 59 in the previous year.—*Indian Agriculturist*, Dec. 7th.

MR. ROBERT'S OPINION ON THE LATE FALL IN PRICE OF CEYLON TEAS.

LONDON, Nov. 29th.

The late fall in price of Ceylon teas has been the subject of remark by me in several recent letters, but as it was not until the present week that the opportunity occurred for my speaking with Mr. Roberts on the subject, it was not possible before now for me to tell you his opinion on the matter. To the causes or this diminution that have been previously men-

tioned Mr. Roberts has added one that is very likely to have strongly contributed; but it will be better for me to record what he mentioned to me as nearly in his own words as it may be possible for me to do from recollection only. He observed to me: "Primarily there is little reason to doubt that the stimulus which sent up the price of teas so abnormally until within the last month or so was due to the depletion of stocks in the hands of country traders which resulted from the cessation of supply to them during the period of the dockers' strike. When that cause ceased to be operative, it was some time before ships could be fully unloaded and their cargoes placed on the market. At the same time there was a marked absence of the lower grades of Indian teas from the market. Both these circumstances made the supply far below the requirements of the trade, which were unusually heavy from the depletion I have mentioned. It was not surprising therefore that those who could afford to do so held back for terms, and then the dealers were perforce obliged to concede, their wants being so pressing. When these were satisfied, however, and the quantity of supply was increased by the arrivals of Indian tea, they refused to buy at the rates they had been before content to give, and which had averaged as high as 13½d all round. Naturally, therefore, it was not long before the reaction was felt by the market, and Ceylon teas fell somewhat, until the average of about 11½d was established which seems to be about the present figure, and which will probably remain so until after the New Year. Why do I predict this? Well I'll tell you, and you will see that the reason to be given has also contributed to prejudicially affect prices for quite the last two months. About the beginning of October the grocers begin to buy their stocks of dried fruits for Christmas. This is an article which has a very short prompt, much shorter than is the case with tea. They must therefore have as much ready cash for making the heavy payments for such fruits in hand, and while they are thus pressed they will buy as sparingly as they can of all other goods, including of course tea. That matter restricts them as to buying all through October and November.

"Then, when December sets in, there is another contributory cause to slackness of buying. It is the wish of great numbers among traders of all kinds to show as large a balance to their credit in their bank-books when made up at the end of the year as possible. This always seems to me a very ridiculous aim, because, having had a good deal to do with banking myself at one period of my life, I know that bankers think nothing of large balances at any particular time. It is the average throughout the year that they specially look to, and the balances are regarded as they stand day by day, not at the seasons when the customer's books are made up. But nevertheless the fashion is prevalent, and grocers among others follow it and will restrict their purchases as much as possible so as to accumulate cash in their bankers' hands at the close of the year. Therefore it is that I should say you will not again observe an upward tendency in the tea market until the New Year opens."

Mr. Roberts proceeded:—"You ask me if I fear any further downward movement. No, certainly I do not. I think equilibrium between supply and demand is for the present established, and the country traders are more willing to pay the current rates, and only this morning I have sold lots I withdrew yesterday from the public sales at the full price for which I held out. Then the plethora temporarily caused by the inrush of the medium lower grade teas has been worked off, and therefore, in spite of the causes which I have

mentioned to you as restricting free purchases at this season, there is full evidence that the country dealers can and are willing to pay present prices, and the supply is not so ample as to cause forced sales, which always of course depress prices. There does not appear to me any reason to fear an increase to the present restricted receipts of China teas. These have been forced out of the market, and this exclusion is too normally established for there to be any inducement offered for increased importation consequent upon the late abnormally high prices, the causes of which were of course well-known to the trade and their evanescent effect fully foreseen by it. I cannot at all anticipate that we shall again see Ceylon teas down to the wretched prices of the latter end of last and the beginning of this year. If popularity is daily extending, and we are more and more called upon to supply a demand for it, China cannot again resume the competition which resulted so disastrously for it during the period mentioned and which gave rise to the low prices of 7d and 7½d for Ceylon souchongs. I doubt very much if the average price for these will ever again vary to below 9d for teas of ordinarily good quality. As to the future outlook for Ceylon growths, I feel the utmost confidence, for effort to popularize it, strongly as this has been made, is daily extending in every direction. I myself am doing all I can to aid in this, and when I hear of a fancy bazaar I make a present to it of a quantity of the finest Ceylon tea I have, and you would be surprised at the number of orders that flow in from those who have purchased these free gifts. It is an admirable method of advertising the teas, because people will purchase readily for charity where no amount of inducement offered by the shopkeepers will tempt them out of their beaten tracks.

"What I fail to understand is, why your people in Ceylon should have such constant attacks of dread for their future. Very likely what you say as to the want of capital behind so many of them largely accounts for such periodical panics as you come to consult me about; but, take my word for it, they are both needless and groundless. The future of Ceylon teas is assured, and you may go on extending and extending their cultivation without the least fear of overdoing it. We can take all you can supply and more, and glad to get it." Although having little doubt myself that Mr. Roberts's predictions are well-founded, I shall watch anxiously the course of the tea trade during the next few months. If he is right it would seem that present prices will remain about stationary till January commences, and that there they may go up about a penny the pound all round.—London Cor.

PLANTING IN QUEENSLAND.

From the letter of a well-known old Ceylon planter, who has adopted our *sobriquet* of "The Wanderer," we quote as follows:—

"Queensland, Nov. 12th.
"It's an up-hill work to get a new industry established against a crossgrained community. Last week I received a small consignment of cacao (seed) pods from your fertile island. They took 26 days to get to me after the boat arrived (about 150 miles). I don't know where they had been hawking them about nor either the purpose. But of course I am the sufferer: they are useless although not rotten. This is my 2nd attempt. I must have more by this time on the way, and am again to try other two lots before I give up. A few plants I have are doing fairly well, but we are having a very dry season, the showers are very light, then comes down the sun proper—not a day but 100 in the shade and sometimes more, but the evenings are always cool.

"I am very glad to see by the *T. A.* that a bright speck appears for your future good in Ceylon new products and go-ahead is your cry. The tea is your standby: it is always increasing in favour; all the people here say Kintyre estate is the best tea we have had for a long time. I see you notice our crash on the sugar industry: this style of colonialism will when it is too late find out its mistake. At present neither cacao, coffee, fruit nor anything else can possibly pay. Still, I am determined to introduce them at their best."

COCONUT OIL PROSPECTS.

There is an impression in some circles that the coconut oil market will suffer an important decline after the turn of the year, on account of liberal supplies being afloat and ready for shipment. Such a belief is pronounced erroneous as stocks are in a position favorable to higher prices. The vessels on the way with Ceylon oil are the "R. Morrow" with 300 tons, due Nov. 15th, the "Holmsdale" with 650 tons and expected daily to arrive, the "Glenesslin" with 750 tons will come to hand about midwinter, to be followed by the "Veronica" and "Lansfield" with moderate amounts. The cargo of the unfortunate "Fede Speranza" is expected about Jan. 1st on the "James Wishart." Large consumers have anticipated their wants and bought most of the stock afloat, thus leaving very little to go into store. It is claimed that the market was seldom in a better position than now exists, and that a firm feeling is likely to rule for the next eight months. Although consumption is largely on the increase, the amount annually distributed in the United States for that purpose being placed at 6,000 tons, there has been an important decrease in exports from Colombo. The total quantity shipped during the year ending Sept. 5th only reached 286,537 cwt.s., in comparison with 328,767, for the previous year. This is accounted for by the fact that low prices discouraged production, which has been limited to a greater extent recently. Cochin oil is consumed in the United States to the amount of 1,000 tons annually, but the local market has been bare of supplies for some weeks because values are below the views of shippers on the other side. Only two small lots are on the way, the "Suffolk" bringing about 150 tons and the "R. Morrow" 275 tons, most of which has left first hands. It would not be surprising to see a higher range of prices all around before the opening of the new year, and some operators are cutting their cloth accordingly.—*Oil, Paint and Drug Reporter.*

CEYLON TEA IN AMERICA.

INTRODUCTION OF CEYLON TEA IN TO AMERICA—SOME VALUABLE SUGGESTIONS—AMERICA'S TRADE DODGES—THE FORTHCOMING EXHIBITION AND THE REPRESENTATION OF CEYLON ADVOCATED.

Philadelphia, Nov. 6th.

While in new York, I called on Mr. R. Macgregor who was formerly in Colombo, and from him I got the address of Mr. R. B. Arthur, formerly on Kirkoswald estate, who is now acting for Messrs. Davidson of Belfast, as their agent for Sirocco Tea. I had several long conversations with him on the subject of our teas, in America, as well as with Mr. Murray of this city; and their remarks, coupled with my own experience during my trip, inevitably drive me to the conclusion that the introduction of our teas will be an exceedingly difficult and slow undertaking. It must not be understood that I am hopeless on the subject, but I doubt if your American Company appreciates the difficulty. Our teas are already known, but no one wants to buy them and very few care to drink them. The reason grocers do not want to buy them is that their trade channels already established are filled with Chinas and Japans, for which they have a ready sale and from which they make a larger profit than they can hope for out of

Ceylons; and the public won't drink our teas (*i.e.* won't buy them) because they are thoroughly accustomed to the other kinds and because they don't know how to make tea (in the pot). It is left to the servant man or girl, and if you only knew what the American domestic was like, you would not wonder at the awful decoctions of tepid water that are often served up as tea.

In nearly every large city I have visited I called on one or two of the leading wholesale men, and in every case I have found Ceylon tea *known*, but all united in saying that it won't sell pure at any rate for a long time to come, and none were disposed to take it up and push it. The American business man is not going to push Ceylon tea unless he sees his way to making more out of it than he does out of Chinas and Japans; and so long as the public know nothing about the tea they are drinking, the trader will go on pushing these cheap impure teas. These then are the primary difficulties which must be overcome, and you (and the Company) can readily see they are not inconsiderable. I think they *must start by mixing* and swallow their pride. For the American cares nothing and knows less (!) where the article comes from or how it is made. He must have something that he likes; and candidly I believe he can be made to like a good deal if you have a smart enough man to help it over his throat. Blending therefore is in my opinion the first step to success. Abandon the idea of selling Ceylon tea as Ceylon tea, but adopt a brand—the more attractive the better—and push your brand, not perhaps, entirely putting "Ceylon" out of sight (for it might come in afterwards) but at any rate keeping it in the background.

If your Company can see their way to improving the efficiency of the average American "slavery" (Max O'Rell calls them "reduced duchesses") they will have overcome the next most serious difficulty and laid this vast Continent under an obligation which no amount of tea buying on its part could ever repay; but inasmuch as this object probably does not fall within the articles of Association of the Company I had better pass it over.

Spending three months in the States is far from sufficient to give one any intimate knowledge of business men and business practices here. But I claim to have made a pretty good use of my time, and though I only wish my opinions to be taken for what they are worth, I venture to send them as being possibly of some little value and at least quite impartial. Business here is to a great extent a game of "bluff" (English, deceit and lying!), by which the contents of the pocket-book of the purchaser is to be transferred to the pocket-book of the seller. Never mind how the transfer is effected, but transfer it. Conscience is entirely out of place, especially with a new article. Success then in great measure depends on the ability of the business man to "bluff" artfully (*i.e.* to conceal the art!) There are many other little dodges in trade peculiar to America or at any rate better developed there which only an American can successfully cope with (unless one has been a very long resident), and I believe it is a mistake sending Englishmen here to *start* a new thing in trade.*

I do not wish to be understood to undervalue the services of those gentlemen who have been working Ceylon and Indian teas here. Not at all. *They have bought their experience* and paid high for it. But I would humbly advise the Company to employ Americans as much as possible, retaining the services of an Englishman as their trust-

* Mr. Pineo is more Yankee than English, a Nova Scotian, and knows the American tea trade well.—Ed.

worthy manager, until they knew something more about the business at any rate. They will have to be prepared also to face immense outlay in advertising and distribution of bills and samples, and rent, before seeing a penny of profits. But if they can hold on long enough and work skilfully (on this side especially) I believe they will come out all right.

I think there is every indication that Chicago will succeed in having the 1892 Exhibition held there; but no matter where it is Ceylon ought it to put her best foot foremost to secure adequate representation. Mind it must be Ceylon with the Government thrown in and not merely the P. A. with a Tea-house. Probably any benefit that does arise will be through your tea, but that can be no excuse for the Government remaining out of it. Unknown foreign lands (among which catalogue Ceylon) have a great interest for the average American and if a fairly good Exhibition of native marvels (barbaric and otherwise) can be got together, much attention will be attracted.

While in Washington, through the kind offices of a friend I had an interview with the Secretary of the Board to promote the holding of the Exhibition at Washington (capital of the States). He was sanguine that ultimately all would agree to Washington, after the other candidate cities had cut each other's throats. But I think he is wrong. Chicago has worked indefatigably for it and got some ten or twelve million dollars subscribed against the 2½ millions of New York. If held at Washington it will be a Government controlled affair entirely, but if at Chicago probably a Syndicate will work it. However I explained to the Secretary what the C. P. A. would want and specially warned him of difficulties with the refreshment contractor, not because he is in a position at present to do anything but because if the Exhibition is held at Washington, I am pretty sure he will be on the Board of Management and the matter might then be recalled to his mind.

A. MELVILLE WHITE.

AMORPHOUS QUININE LIQUOR.—A parcel of 600 bls. of this article, imported about four years ago for account, we believe, of the Indian Government, was declared for sale at last week's drug auctions, but did not actually figure in the catalogues. The lot was put up for sale in 1885, when it first arrived, but could not find a buyer at that time. As the article is of some theoretical interest we secured a small sample, and in the limited time at our disposal have made an analytical examination of it, the results of which deserve to be placed on record. The liquid has all the external characteristics of liquid extract of cinchona; it is of dark brown colour and of the consistence of a thin syrup. But the aroma is very poor—not at all like a bark extract. The taste is distinctly bitter. We found that it responded abundantly to alkaloidal reagents, and a quantitative test showed that all the supposed colouring matter was precipitated by alkali and was taken up by the alkaloidal solvents (chloroform and benzolated amylic alcohol,) and the liquid thus proved to be a solution of amorphous cinchona alkaloids in combination with sulphuric acid. We obtained 20 per cent of the amorphous mixture from the sample. The liquid probably consists of the mother liquors derived from the manufacture of cinchona febrifuge. It is, of course, valueless, and the holders are evidently aware of this fact, as we understand that they are willing to part with the lot for the cost of the stone jars in which it is lodged, throwing in the liquid free of charge.—*Chemist and Druggist*, November 23rd.

THE NETHERLANDS INDIA SUMATRA TOBACCO COMPANY has received a telegram from the chief manager in Sumatra advising that the company's first crop has been harvested. Although a less number of fields was put under cultivation than contemplated in the spring, the 552 fields actually planted have produced 3,660 piculs, equal to 488,000 lb. English. As, however, the tobacco loses in weight during the process of fermenting and sorting, the net weight at date of shipment will be somewhat less than that indicated above. It is too early as yet to judge of the quality. Since the 1st ult. Mr. S. A. van Someren, who has had over seventeen years' practical experience in the cultivation of tobacco in Sumatra, has taken charge of the estates of the company as head manager. For the 1890 crop the preparatory work for the cultivation of 720 fields has been taken in hand.—*L. and C. Express*.

ORCHELLA WEED may be ranked among the principal articles of trade in Zanzibar. The small-leaved orchella, called malele majani, or malele urima, by the natives, is the variety most in esteem. It is found in immense quantities along the shore southwards from Kismayu down to Mozambique, almost completely covering the low shrubs along the littoral. This accounts for the large admixture of wood and dried leaves belonging to other plants with which the orchella is usually brought to the market, and which is not caused by any wilful adulteration, but purely because the weed, thrown up by the sea, remains hanging in the branches in such quantities as to kill the plants. This orchella, is cleaned and repacked in Zanzibar, the foreign matter in it averaging from 20 to 30 per cent. The coarse orchella-known in the native language as malele uene, or malelaja Brawa, is found northwards of Kismayu as far as Socotra.—*Chemist and Druggist*, Nov. 23rd.

THE ANNUAL REPORT OF THE AGRICULTURAL COMPANY for the East Coast of Java has been published, according to which the coffee cultivation is progressing satisfactorily; but the tobacco cultivation has not realised the anticipations which were formed, in consequence of which the managers propose to stop the latter for some time. This unfavourable result is mainly to be ascribed to the condition of the weather. As regards the various estates the following information is given:—At Pareredjo the coffee cultivation comprised 222 bouws, with 458,000 trees. The total cultivation consists of 340 bouws, with 708,000 trees. The soil proved to be very suitable for the coffee cultivation. The expenditure amounted to f.36,657. The tobacco crop, which was far from being encouraging, delivered 413 piculs, for which an average price was made of c.23 27-100 per lb. The expenditure—f.28,135—was not nearly covered. With regard to the estate Kali-Tapah the cultivation comprised 225 bouws, with 350,000 trees of coffee, the situation of which is excellent. The crop was 921 piculs, of which 872 were sold. Information was received that the crop for 1889-90 will be below the estimate. The expenditure amounted to f.36,490, and the 842 piculs realised f.46,781, the total profit being thus f.11,214, which will be used for the other undertakings, which have as yet not given a profit. On Kali-Lebah the coffee cultivation was 70 bouws with 124,300 trees, while a further 70 bouws with 261,300 trees will be worked. The cinchona cultivation consists of 111,520 trees, and the proceeds of 1,000 trees was f.635. The expenditure of Kali-Lebah amounted to f.25,583. The balance-sheet shows an amount of f.558,549 as revenue and expenditure, and, among others, the following items:—Debit: shareholders, f.48,750; Kali Tapah, f.178,800; Pareredjo, f.152,894; Soember Sewoe, f.25,000; Kali Lebah, f.93,427; unissued shares, f.55,800 credit: capital, f.500,000; drafts, f.45,000—the profit being thus f.11,114.—*Amsterdam Cor., London and China Express*.

COMMERCIAL PRODUCTS OF THE
COCONUT PALM.

(COMMENTS ON DR. WATT'S MONOGRAPH.)

The use of the words "The mainland of the Malabar District" evidently arises from the mistake made by the writer that the Laccadives are, for administrative purposes, under Malabar. What he really means, probably is the two West-coast districts of the Madras Presidency, South Canara and Malabar, which have a sea board of over 250 miles. As these districts contain very different peoples, speaking different languages, and with totally distinct customs, it is highly probable that considerable differences may be found in their coir. We would, therefore, recommend that a collection of fibre should also be made from the North of South Canara. The four most northerly of the inhabited islands of the Laccadive group are, for administrative purposes, part of South Canara. The other four inhabited islands with Minicoy, some 200 miles further South, are attached to Malabar. Kiltan is part of South Canara. The Laccadive palm is not cultivated specially with a view to coir, but, as the revenue is paid in coir, that article is the chief staple of the islands. Minicoy is under a different system.

As regards the difficult points which exist regarding the coconut palms, which are expressed on p. 192, by Dr. Watt in question, form:—1. The palm is not grown expressly for coir. The ripe nuts, from which the coir has been stripped, are used for copra. 2. The tree is tapped for toddy. If tapped continuously it cannot produce nuts or coir, as the flowering spathe are destroyed; but, in some parts of South India, it is believed by the natives that the occasional tapping of a tree improves the yield of nuts, and, consequently, of coir and oil. The same tree may yield fibre, oil, and toddy; but trees tapped for toddy are not allowed to yield nuts, and, therefore, do not yield oil or fibre. 3. If the trees are tapped for fermented toddy, in some parts of the Madras Presidency a tax is paid on each tree. No tax is paid on trees tapped for the preparation of sugar. 4. If only one spathe is tapped, other may, at the same time, yield nuts, and, consequently, coir and copra. As a rule only one spathe is tapped at one tree in the Madras Presidency, because, at or about the time that the new spathe becomes sufficiently developed to yield toddy, the yield of the old one ceases. Occasionally one spathe ceases to yield before the next commences, and the tree becomes dry for some days; and, not unfrequently, the new spathe yields before the old one runs dry. 5. The number of nuts required to make a maund of dry copra varies with the size of the nuts.

The statement on page 194, that "on the Eastern and Western Coasts it is particularly abundant, more so towards the South" is scarcely accurate as regards the West Coast, where the coconut palm is exceedingly abundant in the South Canara district. The statement that "all flower in the hot season, the nuts ripening from September to November" is incorrect, and is incompatible with the statement on page 195, that "a coconut throws out a spathe and a leaf every month: each flowering spike yields from 10 to 25 nuts." As a matter of fact it produces a flower every month, and, in the absence of accidents, a crop of nuts is also produced every month. The statement that "the Indian region of the coconut may thus be said to be the lower basins of the Ganges and the Brahmaputra, and the Malabar and Coromandel Coasts" is incorrect. In the interior of the Madras Presidency the coconut is abundant, especially along the banks of rivers, irrigation channels, and tanks. At Ranipet in the North Arcot district, there is a single tope believed to contain 10,000 trees. In the Salem Taluk of the district of same name the tree tax was paid upon 19,398 coconut trees for the manufacture of fermented toddy in the half year ending 31st March, 1889, which is not the season for toddy drinking. In the same half-year 10,410 trees were tapped in the Trichinopoly Taluk for fermented toddy. The Salem Taluk con-

tains 1,072 square miles, and the Trichinopoly Taluk 486 square miles. In South India the nuts are planted with their points upwards, when they are sown. The rate of growth depends on the nature of the soil, the amount of attention which the young tree receives, and whether it is watered regularly or not. In the Laccadives trees sometimes bear in the fourth year. The following figures show the quantities of the products of the coconut palm received from the Laccadives during the last periods for which information is available.

1. Islands attached to the District of Malabar.—

	Coconuts. Number.			Coir. Candies.

One Candy=560 lb.

If compared with the figures given on pp. 206-7 of Dr. Watt's Monograph, the above show that a great deal of the West Coast coir is manufactured on the mainland.

Lastly, it may be mentioned that the green nuts are not used for coir-making. The ripe nuts are useful for fibre.—*Madras Mail.*

THE FIBRE INDUSTRY IN TRINIDAD

was thus discussed at a meeting of the Agricultural Board of the Colony:—

Professor McCarthy said that his motion for the importation of a small decorticating machine explained itself. There were several valuable fibre-producing substances here, but the mode of extraction was very tedious and a good deal of fibre was lost. His Excellency the Administrator suggested that he should bring this motion forward in order that the exact proportion of fibre in each plant should be ascertained. Some of the fibres were very valuable, but they were in non-paying quantities, and such a machine was required in order that definite information could be obtained.

The Chairman said there was a Report received from the Royal Gardens at Kew on the fibres obtained from plants grown at the Bocas islands, and he understood that it was reported that they were equal to Sisal hemp. The Government had also communicated with the English Consul at Yucatan. There were one or two plants in the Botanic Gardens which were supposed to be the true Sisal hemp, and it was proposed to propagate them as much as possible. A part of Naparina, and also from Arima northward towards Matura, and away again towards Sangre Grande, were magnificent fibre-producing districts which were now utterly useless and there was not the slightest doubt that plants would, grow a great deal better there than they did at the Bocas. Members had seen the Report of the person who was sent from the Bahamas to Yucatan to report on the fibre industry there, and he thought that from sixty thousand dollars' worth they had gone up to about four or five hundred thousand dollars a year, and always found a ready sale for their fibre. It was a product in constant and increasing demand. The industry was started in Yucatan by means of the Mexican Government wisely putting a very heavy tax on all lands that were not planted with Sisal hemp. Rather than lose their lands the people planted them, the consequence being that the country was flourishing instead of being

a miserable place where one lived from hand to mouth and simply grew enough provision to live upon. He said that from his knowledge of Yucatan, having lived for some years close by, he dared say they could get a machine. The Indian Government had offered a prize of \$5,000—(Mr. Devenish: So has the British Government). There were a great many machines exhibited at the New Orleans Exhibition. He (Mr. Fowler) sent tons and tons of fibre (from Honduras) for the purpose of being tried at that Exhibition, and there was one machine which was a great deal better than the rest, and could have been obtained for £20; but you could not get one machine to give every kind of fibre—each fibre must be dealt with by a machine suited to its peculiar constituents, and we were waiting for the engineers or mechanics to invent one that could be used for all fibres. They had planted the Ramie at the Convict Depot at Chaguanas, and had sent some fibre the other day to be tested. It was essential to move about the districts where there were fibre plants, to get the fibre and see what would be the result of the products we had got. The one essential thing was a constant stream of water. The Board would no doubt recommend that a machine should be obtained. It would be worked at Chaguanas by prisoners.

Mr. Riddell was understood to say he had gone into the particulars with Engineers in London and Belfast, and had come to the conclusion that to manufacture fibre would be impracticable unless there was a plentiful supply of water.

Mr. T. Warner said the lands at Arima just referred to had plenty of rivers running through them.

Mr. Anderson, alluding to the nature of the land spoken of at Arima, said that fibre took such a large amount of nourishment from the soil that it would be found in a year or two that the plants would not yield anything unless they were manured.

The Chairman: How do they grow at the Bocas?

Mr. Anderson: Because they have never been reaped, but the moment you go into cultivation the land will not yield; neither will the land at Arima. It would be a dead loss of time and money to grow fibre on such land as that.

The Chairman: I think I may undertake to say that there will be a field laid out at our Model Farm at Chaguanas.

Mr. Anderson: But it is a great deal better than the land at Arima. That flat at the Depot is a great deal better.

The Chairman: I propose to get plants from the Bocas and have four or five acres of land at the Depot planted, and see what the result will be.—*Agricultural Record.*

MALDAH MANGOES.

(From the Proceedings of the Agricultural and Horticultural Society of India.)

Read the following letter from the *Indian Agriculturist* of the 22nd June: "To the Editor, Sir,—I see in the report of the Agri-Horticultural Society that enquiries have been made by Mr. Samuells about Malda mangoes. All the good Malda mangoes are described in Mr. Maries' work on mangoes. This work is now, we hear, in the hand of the Agri-Horticultural Society to be published if funds are forthcoming. This ought not to be difficult, considering the number of Members in the Society, and the value of such a work.

Malda' mangoes are known in Calcutta only as *Fuzli*, a big coarse fruit which I certainly class as 2nd rate fruit. The history of it was given some time ago by Mr. Reily of the Ochanal Estate, Malda. Malda mangoes in Saharanpore, Lucknow, and other gardens in Upper India are the celebrated *Shah 'Pusund'* (Shah's favourite), a big irregular shaped fruit, sometimes weighing 3 lb., and I think a better fruit than *Fuzli* to eat. This is also common in Malda and Tirhoot. It is marked No. 18 in Mr. Maries list and rated 2nd class. The best Malda mango is *Gopal Bhog*, the food of the god Gopal. This is a dirty-looking small fruit, spotted and speckled over with black, often reddish peach on the top, and a whitish bloom; it weighs about 6 to 8 oz. only. This equals the finest 'Afooz' from Bombay. There

are several varieties, very much like this, but there are none to equal it. It is a shy bearer generally and not known in the market. I obtained fruit from Chanchal.

"Other Maldas are 'Berrua Malda,' 'Gowraya Malda,' 'Kirsapat,' 'Chipka Malda,' 'Kova Pahari,' 'Subza Malda,' 'Safada,' 'Mobun Bhog,' or 'Ram Pershad,' 'Jhali Bandi,' 'Lamba Budaya,' 'Dishbaz,' the four last being very late fruits. I believe all the mangoes are well known under these names in Malda, and all were planted and many bore fruit in the model plantations lead out by Mr. Maries in Dorbhunga. By the way, writing about these plantations, it would be well if the Agri-Horticultural Society would procure grafts of all sorts of mangoes from these celebrated gardens. Such collections of fruits do not exist in any other place in India. Upwards of 150 sorts of mangoes, all good ones, are there collected from all parts of the country at enormous trouble by Mr. Maries. Most of the grafts made by him were from trees loaded with fruit, so that the names of the trees are correctly given."

AFOOZ.

An estimate of the cost of Mr. Maries' work on mangoes is being prepared; it is proposed to invite subscribers to register their names for copies, and issue the book to them at special rates.

SCALE ON TEA.

Messrs. Mitchell Reid & Co. wrote, handing following extract of a letter from Mr. E. O. Cotes of the Indian Museum, and asking for a copy of the minutes referred to:—

Extract.—"The blight is the same as what was recently discussed at a Meeting (the last?) of the Agri-Horticultural Society of India where particulars of what is known of the pest were given in full. I have not a copy of the minutes of the meeting by me, so would suggest your applying to Mr. R. Blechynden for them. The blight is a species of scale insect belonging to the genus *Lecanium*, and is closely allied to the scale insects* which have done so much towards ruining the coffee industry of Ceylon and Southern India."

A copy of the *Proceedings* for May last was sent to Messrs. Mitchell Reid & Co. who, in acknowledging receipt, promised to advise the society of the result of the applications therein recommended.

MULBERRY LEAF AS FODDER.

Mr. James Cleghorn, in a recent letter, referred to some remarkable results he had obtained from feeding milch cows on mulberry leaf. A cow he had for six months in milk, and which had, when he got her, a six months' calf at foot, continues to give milk, and the quantity has even slightly increased. The effects of a feed of leaf night and morning 2 lb. each time, was apparent even though the animals were eating quantities of other green food. Mr. Cleghorn says:—"I stopped feeding one cow on mulberry and the milk went down from 5 pows to 3 pows, but again feeding her for three days on a *seer* of leaf morning and evening she is now giving her 5 pows again. I have a good deal of leaf now, and during the past five days the cows are having good feeds of mulberry and the milk supply is giving up."

Mr. Cleghorn has promised to communicate the result of further trials of this novel fodder.

GEMS IN CEYLON.

MR. BARRINGTON BROWN AND THE GEMMING ENTERPRISE IN CEYLON.

We give Mr. Barrington Brown a cordial welcome to the island. A great deal depends on his visit at this time, and it is satisfactory to know that tried reputation, skill and long experience in connection with the matter which he is to investigate, prevent any question or doubt as to our visitor being the right man in the right place, to report on the gemmiferous country and the prospect of establishing profitable Gemming and Mining industries in Ceylon. We need not repeat how the island has been famous for its precious stones any time during the last 2,000 years—how its fame

has extended far and near in Asia as well as to Europe in Greek, Roman, Venetian and more recent times. The gem-yielding country of Ceylon covers a wide region and many and diverse have been the experiments made in the Central, Western and Southern Provinces, to gather a harvest of gems, among the latest being that of Sir Samuel Baker below Nuwara Eliya and Horton Plains. But there is a significance in the fact which will be duly appreciated by our visitor that the natives for generations seem to have had certain defined favorite localities, and yet these are so wide apart in some cases—including Ratnapura, Rakwana, districts around Matara, below Balangoda in Maskeliya, and the Moon Plains, Nuwara Eliya—as to lead to the belief in a wide field for the expert and, as we hope, the resulting Gemming Companies.

Dr. John Davy (brother of Sir Humphrey Davy) was one of the first to write intelligently and scientifically about the "Gems of Ceylon," and Mr. Barrington Brown has no doubt already read all that he and others have to say on the subject, in the volume "All About Gold, Gems and Pearls in Ceylon" which we have endeavoured to make a repertory of all that is useful on the subject. One thing is clear, that neither Burma, South Africa nor, perhaps any other country, yielding precious stones under the sun, can compare with Ceylon in the conveniences offered for developing any large industry of the kind. We have a peaceful settled country, well served by roads (if not by railway) with the cheapest and most reliable of labour supplies, with good acclimatised supervisors ready to hand; a climate on the whole fairly good, the seaside and our cool hill regions being within easy reach; and we trust we may also add in this matter—though the proof perhaps has yet to come—a Government enlightened and progressive enough to understand that it is for the interests of Ceylon and its people to give every possible encouragement to Mr. Barrington Brown and his principals and agents in a work which may be the means of bringing large amounts of capital for the development of the island.

We are aware of the hard work done by Mr. E. G. Harding—who is back looking like a giant refreshed after his holiday—in promoting the Gem Syndicate and by Mr. W. Saunders in making arrangements about land leases and concessions at this end; and we know that the promises of support from some of the wealthiest of London Brokers and Capitalists, make it very certain that any amount of capital required will be forthcoming at once, on the conditions now to be worked for, being fulfilled. We have always gone on the broad fact that if Upper Burma is deemed a favourable field for the establishment of an important Gemming Company, much more ought Ceylon; and this has been the mainspring of action on the part of the Messrs. Saunders and Harding in getting up the preliminary Syndicate (some shares in which at Mr. Harding's urgent request have been reserved for Ceylon), to be followed in due season by a large Company if all goes well at this end. The second point, on which we have dwelt in opposition to a good many old colonists and would-be authorities who had pooh-poohed the idea of Europeans getting the gems even after being found, with coolies ready to conceal and even swallow them at every turn,—is the immense advantage of working with modern machinery. Our expectation is most fully confirmed as to machines now existing which absolutely preclude the risk of the loss of any stone caught up in the excavations, the same being carried on, until by specific gravity it is separated and deposited in a receptacle available only to the manager.

In the meantime we have to await the result of the prolonged and careful examination of our gemming country by Mr. Barrington Brown. It is not likely he will leave Ceylon, or arrive at definite conclusions on which to base his final Report, much before February. The weather is, of course, henceforward all in favor of operations. Mr. Barrington Brown who arrived yesterday by the S. S. "Lusitania" is at present the guest of the Government Agent for the Western Province. He is likely to visit the gem-cutting establishment of Mr. Louis Siedle this afternoon, to see the local manipulation of some of our stones. On Saturday he will probably accompany Messrs. Harding and Saunders to Dikoya—the holidays being so close at hand—and have a look at Maskeliya, Bogawantalawa (and perhaps the Moon Plains, Nuwara Eliya) before travelling down via Balangoda to Sabaragamuwa. We feel sure that whatever be the professional outcome of his visit, Mr. Barrington Brown will see much to interest him in his visit to the island, and his Report is sure to be full of scientific as well as commercial interest. It is a disgrace to the Ceylon Government that the Geological Survey of the island which we have been urging for twenty years back, has not yet been undertaken. Mr. Wm. King, now at the head of the Geological Survey of India, was very keen about it when as a junior he used to visit his brother in this island about the time we mention. But we may well hope that as one result of the present enquiry about gems, this survey will not now be much longer delayed.

USE OF WIND POWER IN CEYLON.

As might be expected, the Dutch, who carried their great institution of canals to Ceylon, did not neglect the allied appliance for drainage and water-raising, in the shape of windmills. They used wind-power for a different purpose, however. Christoph Schweitzer, whose quaint and interesting account of Ceylon more than two centuries ago is appearing in the *Literary Register*, in describing the Colombo Fort of 1665 wrote:—"There is also a Powder Wind-Mill by *Port de Gala* [the gate facing Galle, which we remember as the South Gate] and by the *Water-Pass*, a Wind-Mill to saw Boards, &c.)* This is very interesting, and perhaps some of our friends learned in the Dutch lore of the colony may favour us with any further references to the use of wind-power by our predecessors which they may find in records or respecting which the older Dutch descendants may have traditions. We should like especially to know whether windmills were utilized for draining swamps or lakes or in raising water for irrigation. It is a question of cost, of course, as to whether a small moveable wind mill could not be used to raise water from a lower level to higher in paddy-fields, instead of the large *ola* baskets slung with ropes now in use, and also in some places in supersession of the "well-whip," used in Jaffna to raise well water for irrigation, and in Colombo and other places to fill bath tubs. Beside first cost of a windmill, which ought not to be high, there is, no doubt, the difficulty of arranging the sails, so

* These mills are referred to by Dr. Daalmans in his notes on Ceylon (1687-89) translated in the *Literary Register* II, p. 303, as follows:—"Here [near the Waterpass] stands a saw-mill worked by wind.... Close to the Galle Gate there stands a powder-mill, worked also by wind, where gunpowder is manufactured." This powder-mill was built by the Portuguese; but we believe that in their time it was worked by a water-wheel.—Ed.

that they should not suffer in gusts of wind. We recently mentioned that the late Mr. John Armitage contemplated draining the great Muturajawela swamp on the north side of Kelani river near Colombo, by means of wind mills. We do not know the reason why the design was not carried out, and we should like to know what engineering or other difficulty there may exist to prevent such operations on a large scale. In our previous article we mentioned the fact that the late Dr. C. Elliott superintended the construction of a windmill at Colombo, which was quite successful in raising sea-water for a swimming bath. Curiously enough the next we hear of a windmill in Ceylon in the British time is from our late friend's son, in his Administration Report of the Southern Province, including the Galle Municipality, for 1888. This time the windmill is on the ramparts not of Colombo but of Galle fort. Here is Mr. Edward Elliott's account of this "ingenious device" for raising salt-water to flush the drains of Galle:—

Amongst the measures taken, an important one was the erection of a windmill on the ramparts for raising salt-water to flush the drains of the Fort and water the streets. The military authorities allowed one of the old batteries to be converted into a reservoir capable of holding about 25,000 gallons, which is filled by the pump attached to the windmill.* For the present the distribution is carried out by carts at a cost of R1 per diem, as the cart is filled by gravitation direct from the reservoir. 2,500 gallons a day are thus distributed for flushing and watering. Under the old system, when the cart had to be taken out of the Fort and filled by hand, the cost was R4 per diem for four or five trips. The windmill pump and reservoir cost about R 1,000, and it is calculated will clear itself in between two and three years, while it admits of some four times the amount of flushing and watering being done, with great benefit to the health and comfort of the Fort residents during the hot weather. The intention is in time to provide flushing cisterns at various points, which can be rapidly emptied into the drains at regular intervals, and to connect them with the reservoir by piping. A length of a thousand feet of drainage pipes has been ordered from an Indian firm for experimental purposes. If found suitable they will permit the above intention to be carried out at a comparatively small cost.

It would appear from the details of this very interesting experiment that the best weather for the operations of the windmill is, when the movement of the air exceeds 7 miles an hour up to twice that rate. As 27 miles an hour means a gale, we are not surprised to learn that "sail had to be shortened" when the force of the wind was represented by 21 miles an hour. We should be glad to hear the history of the experiment up to date. In his diary Mr. Elliott refers to the windmill and pump thus:—

Our windmill has been set up, and is found to answer. There is almost too much wind just now, but the crucial time will be in the hot weather next year. It seems, however, to require very little wind to work it, and with one-fourth of the canvass stretched the mill throws up 500 gallons of water per hour to a height of 35 ft. into a reservoir. From this it will be removed by a large water-cart and the Fort drains flushed daily and regularly at an outlay of about Re. 1½ a day, against a very indifferent service previously costing twice that.

* The following particulars of the working of the pump will probably be interesting:—The water is raised 34 ft. (26 ft. lift and 8 ft. force); but it is found the windmill will not work unless there is a breeze of at least 7 miles an hour blowing. This force will give 1,000 revolutions an hour and pump up 400 gallons an hour. A ten-mile breeze gives 1,240 revolutions and 430 gallons. The maximum raised has been 530 gallons (with 1,450 revolutions) when the wind travelled 21 miles in the hour by the anemometer, and sail had to be shortened for fear of accident.

Supposing we worked two-thirds of the year, this gives a saving of R360 a year against an outlay of about R1,000. If time should confirm these experiences it is proposed to obtain a bigger pump and provide a larger reservoir, from which the water will in time be conducted by pipes to flushing reservoirs at the head of each main drain. Salt water is a splendid disinfectant and these frequent flushings will keep our drains free from foul gases, I believe.

If the Galle experiment continues to be successful it might be well for the Colombo Municipality to utilize salt water after a similar fashion for watering roads as well for flushing and disinfecting drains. In Dr. Elliott's more modest experiment, the water was raised by the buckets of a "Persian wheel."

It strikes us as just possible that the officers of the Forest Department might take a hint from the employment by the Dutch of wind-power for sawing timber. Of course the agency of the steam engine, of which the Dutch of two centuries ago knew nothing (and so with the English) is now available. But we should think that windmills could be rigged up more speedily, shifted with greater facility and would be altogether more economical than steam engines?

CEYLON TEA AND MR. R. E. PINEO IN AMERICA.

(From the *Tacoma Lodge*.)

R. E. Pineo, manager in America of the Ceylon Planters' American Tea Company, yesterday made inquiry among the local jobbers relative to the sale of Ceylon tea in this market. He was greatly encouraged, and will probably open a house in this city for the distribution of Ceylon tea in the northwest. The local jobbers assured Mr. Pineo that they had no doubt but that the brands of tea which he proposed to furnish would sell freely in Washington and throughout the northwest. However, under the present shipping arrangements, they could not undertake to handle the Ceylon tea direct from that country. They urged Mr. Pineo to establish warehouses in this city, from which they could supply their demand.

"I am considering the proposition to establish a branch tea house in this city," Mr. Pineo said, "and shall undoubtedly do so if some one of the local jobbers do not handle our tea. I am confident that the people of the northwest will prove heavy consumers of the Ceylon tea when once they become acquainted with its superior qualities."

"The Ceylon tea would cost more—for various reasons best known to the trade—than the Japan or China tea, but it is a far superior tea, and one pound of it will go as far in the kitchen as one and one-half pounds of any brand of tea that is imported from China or Japan. Then too, the Ceylon tea is much more wholesome than the China or Japan tea. It is not mixed with drugs in order to give it flavor, and it is free from all foreign and poisonous substances that are found by chemical analyses in the China and Japan brands."

Mr. Pineo leaves by this morning's boat for Vancouver and Victoria, and will subsequently proceed to Chicago and New York. He says the Ceylon tea which will eventually reach the Tacoma market must come via Hongkong to either San Francisco or Vancouver. The establishment of the proposed steamship line between Tacoma and Hongkong, he said, would encourage the Ceylon and India tea business. Besides the proposed line of steamers would be patronized extensively by the Ceylon and India tea merchants, which would in turn be an encouragement to the speedy establishment of the new line.

R. E. Pineo, of Colombo, Ceylon, accompanied by two native servants—a man and his wife—of that country, arrived at The Tacoma last evening (Nov. 7th) after a pleasant overland journey from San Francisco. Mr. Pineo's servants were attired in the picturesque attire of their native land, and attracted much attention. The man wore a highly colored turban, and his wife's ears and nose sparkled with jeweled ornaments.

Mr. Pineo was found in the lobby of the hotel during the evening and told a very interesting story regard-

ing his visit to America. "I have crossed the Atlantic eighteen times and this is my second tour around the world. I have lived in Ceylon thirty-one years, and have watched closely the growth of the tea industry in that country and in India.

"The object of my visit to America is to establish new agencies for Ceylon tea. An agency will be established in San Francisco, and, sooner or later, there must be a house for the distribution of our goods in Tacoma. I do not know whether I shall be able to establish the house at present or not. Tomorrow I shall consult with several of your local merchants. Most of our tea now goes to England. Last year we exported from Ceylon 35,000,000 pounds of tea, and from both India and Ceylon 185,000,000 pounds were exported. The average jobbing price received for the same was 24 cents, this being much higher than the average price received by the Chinese exporters, as our tea is far superior to the Japan and China tea. Ceylon and India tea is the only machine-made tea in the world. All other tea is made by hand.

"In 1873 we exported 278 pounds of tea. It was then doubted that any one besides Chinamen could make tea. Now, the Chinamen are coming to us to learn how to make tea. The superintendents of our works are all Europeans. At present there are 200,000 acres under cultivation in Ceylon, and 300,000 persons, each receiving on an average 13 cents a day, are employed. These laborers save 50 per cent. of their wages, as it costs them only 6½ cents per day to live.

"The condition of the lower classes in Ceylon and India is improving. The castes are being broken up, and 300,000,000 people are kept peaceably with only 66,000 soldiers."

Mr. Pineo represents the tea merchants of Ceylon. His servants receive \$300 per annum for their services. The woman is 20 years old and has a child 3 years old. Her husband is aged 23. In addition to several rings in her ears and nose, she wears silver anklets and gold rings on her toes—so Mr. Pineo says. Some of her costumes are very elegant.

"JAMAICA SARSAPARILLA."

With a paper parcel we received the following letter from Mr. J. P. Abraham:—

"I beg to send per bearer a sample of fresh Jamaica sarsaparilla roots this day taken out from 8 inch pots. They are of from 3 pots which weigh fresh. The plants are 15 months old in pots, and never planted in ground, all of the 3 pots seems full of roots. I am glad if you could kindly forward the sample for valuation and of their analyze as the cultivation of Indian Sarsaparilla do not require any attention nor good manure, and can be easily grown from sea level up to any elevation, it is a very hardy variety, the parent plants being imported from Jamaica Botanical Gardens."

We referred the letter and specimens of drug to Dr. Trimen, who has courteously responded after the following interesting fashion:—

"The sample sent is a rather poor one, the roots being too young and not of full size; no doubt also growth in pots has somewhat hindered their full development. In ordinary trade samples of this sort of Sarsaparilla the cylindrical roots are considerably more in diameter and the large mass of fibrous rootlets ('heard') is usually absent, having been trimmed off before sending to market.

"There are some curious points connected with this product, which has been cultivated in Jamaica for many years past. The plant is not native there, and its geographical origin is not ascertained; nor has it ever been botanically determined with certainty. Moreover this drug, though certainly a Sarsaparilla from Jamaica, is not the 'Jamaica Sarsaparilla' of commerce. This latter is a product of Central America and obtained its name in consequence of coming by way of the W. Indian Island. It differs from the kind before us in the dark reddish-brown colour of the root-bark which has very little starch in its structure or as it is termed in the trade is 'non-mealy.' It is this sort that is most sought after by druggists. The sort

grown in Jamaica is much paler in colour, more starchy ('mealy') and is less valued in the English market. Its cultivation however is still carried on there to a considerable extent and is said to be very profitable; the export in 1870 was 1,747 lb. and in 1871, 1,290 lb., I have seen no later returns.

"I do not think the culture of Sarsaparilla advisable here, at least on any large scale. The reputation of the drug, once very high, has been falling for many years, and by many therapeutists and practitioners it is now regarded as almost if not entirely inert. Careful chemical analysis has not revealed the existence of any alkaloid with important properties, and the use of this once famous tonic is steadily diminishing."

H. T.

Here are two strange revelations: first as to the doubtful origin of the plant and then as to the scepticism which has arisen regarding the efficacy of what was once deemed a potent tonic and "purifier of the blood." There is a substitute for Sarsaparilla which grows wild in India and Ceylon which was once in high repute. We recollect Dr. O'Shaughnessy of Calcutta analyzing it, and we believe his report was favourable. In Jaffna we heard that natives thin of habit, went through a regular course of sarsaparilla, when appointed to a Government office in order to obtain a degree of obesity necessary to secure full respect from the people!

By a curious coincidence, after passing Dr. Trimen's adverse judgment to the printer, the *American Exporter* reached us, with an advertisement commencing thus: "Your last chance to regain health, is Ayer's Sarsaparilla—the well known standard blood purifier. If you have never tried it, begin at once," &c. Then follow certificates of cures of blood poisoning, scrofula and carbuncles! But medical science and quackery are two different things. Only where is the process of disillusion to stop?

"INDIAN AND CEYLON INSECT PESTS"*. *

(Third Notice.)

But we now come to an insect of special local interest, not only because it attacks tea, but because it is named after the late Dr. Thwaites of Peradeniya.

A CATERPILLAR INJURIOUS TO TEA AND SALT.

Dasychira thwaitesii, Moore.

Plate III, fig. 1, a imago ♂, b imago ♀, c cocoon in tea leaf, d pupa, e larva (dorsal view), f larva (side view), all natural size; fig. 1, g, *Chalcis euclypea*, Hope (enlarged); fig. 1, h *Perilampus*, new species (enlarged).

NATURE AND EXTENT OF THE DAMAGE.—Caterpillars and cocoons of this insect were forwarded to the Museum in February 1888 by Mr. Trotman of the Planters' Stores Agency, who writes—the caterpillars "have lately visited our Eastern Doora's tea garden in such quantities as to cause serious damage to the leaf of the tea shrubs."

In the *Indian Forester* is an account by Mr. W. R. Fisher of a caterpillar that defoliated salt trees in the Eastern Doora's and Goalpara in 1878, and which appears to be the same insect.

Mr. Fisher writes that, in the commencement of October 1878, every leaf of the salt trees, in a forest of about two hundred square miles in extent, had been devoured. In this tract, which is situated on a raised plateau of red loam and gravel, and is called the Purbotjuar and Guma forests, and in which salt almost everywhere constitutes the predominant species, the foliage was so completely destroyed that the salt trees were rendered perfectly bare of leaves, and the ground was strewed with their debris, and with the caterpillars' dung.

The caterpillars, however, prevailed over a much larger area, the more westerly forests in the plains of the Eastern Doora's suffering the most. Other trees

* Notes on Indian and Ceylon Insect Pests—with splendidly executed plates—Price R1-25—to be had at Observer Office.

were also attacked, especially *Careya arborea*, and even the tea plants of a garden which had lately been opened out in the neighbourhood of the forest. From some of the villagers Mr. Fisher also learnt that there had been similar attacks of caterpillars within their memory.

THE INSECT, AND ITS LIFE HISTORY.—The insect belongs to the Bombyces moths of the family Liparidæ and has been described* by Mr. Moore as *Dasychira thwaitesii*.

The caterpillars, when full-fed, are about $1\frac{1}{2}$ to 2 inches long, covered all over with long, erect, yellow hairs, a thick bunch of which occurs on the dorsal aspect of each of the first four segments of the abdomen, and also on the terminal segment; there is a black transverse stripe between the two anterior dorsal tufts.

After it is full-fed the caterpillar spins itself up between the leaves of its food-plant, into a scanty cocoon, composed of its own hairs, which appear to be very easily detached and which it binds together with silk. After almost completely denuding itself of hairs to form the cocoon in which it encloses itself, the caterpillar creeps out of its larval skin and becomes a pupa. In the case of the February generation, which was the one that was kept under observation, the insect remained in the pupal state for further observation less than a fortnight. The most noticeable feature about the moth is the difference between the sexes, the male being very much smaller and more brightly coloured than the female.

Mr. Moore describes the moth as follows:—

Male: fore wing, greyish white, crossed by a basal, antemedial, and a post medial, indistinct, black speckled sinuous duplex line, and a marginal side line, a lunular mark at the end of the cell, the lines slightly dilated at the costal end; hind wing, pale brown, the costal border and the cilia, greyish-white; thorax, head palpi and legs, greyish-white; abdomen, pale brown; thorax, slightly brown speckled; sides of head and palpi, blackish legs with black spots; antennæ ochreous brown, shaft white.

Female: fore wing greyish-white, irrorated with numerous brown scales, the transverse sinuous lines much less defined, being mostly apparent at the costal end and composed of scattered brown scales; hind wing white, with a few brown scales from the anal angle; body greyish-white; thorax brown speckled; legs and antennæ as in the male.

Expanse—male $1\frac{1}{2}$ inches; female $2\frac{1}{2}$ inches."

Food-plants; Moore quotes from Thwaites that the larvæ feed on *Erythrina indica*, while from the above we learn that it also feeds on tea, sâl, and *Careya arborea*.

Parasites.—A considerable number of cocoons were sent to the Museum, but almost all of them were destroyed by parasites, of which the most numerous in individuals was a tachinid fly. The pupæ of the tachinid were found in great numbers loose in the bottom of the breeding cage, where the larvæ, after leaving the caterpillars in which they had developed, had no doubt been overtaken by their pupal stage, whilst endeavouring to hide themselves in the ground after the manner of the "silk worm fly" with which they appear to be identical. A few chalcid parasites also emerged, and these Mr. P. Cameron has kindly examined: he finds that they belong to two species, viz., *Chalcis (Brachymeria) euplaea*, and a new species of *Perilampus*. Of these three species of parasites, the tachinid flies, no doubt, did by far the most execution; but the chalcids must have accounted for a certain number of the pest, and altogether the parasites were so effective that out of a very considerable number of cocoons of the pest, which the writer attempted to rear, it was with difficulty that sufficient moths could be obtained for the identification of the species. If, therefore, the specimens sent to the Museum were at all representative of those left on the bushes, but very few moths of the February generation will have emerged to propagate the species, and there can be little to fear from the pest next year.

Dasychira thwaitesii seems to be singularly subject to the attack of parasites, for Mr. Fisher's experience

in 1878 with the sâl pest is almost identical with what has been above described, in the case of the tea pest, Mr. Fisher writes*:

"I collected several hundred chrysalids, intending to send specimens for identification, but they all died, whether from a disease or ichneumon I cannot now determine. Since May 1879 I have not noticed a single specimen of the insect."

He considers that the mortality amongst the chrysalids may possibly have been due to the unusual heat and dryness of the weather in March and April 1879, but the writer is inclined to think that *Dasychira thwaitesii*, like many other insects, is continually kept in check by internal parasites, which have such vast powers of reproduction that, whenever their favourite food becomes abundant they multiply to such extent as very rapidly to destroy the great majority of the insects on which they feed, though they may never succeed in entirely extirpating them.

The tachinid fly has not been described in this paper, as a considerable amount of information has been collected concerning it, and it would seem more appropriate to consider it in connection with the silk worm of which it is so serious a parasite.

Remedies.—If it should turn out, as now appears probable, that the tachinid which attacks the *Dasychira thwaitesii*, is the same as the "fly" that destroys silk worms in Murshidabad and other parts of Bengal, it would seem to be well worth while to ascertain by actual experiment whether the increase of the pest cannot be more rapidly controlled by introducing fly-blown worms from the silk district than by waiting for the parasites to be introduced by accident.

Besides any such possible method of controlling the pest, however, there can be no doubt but that, in any limited area, the caterpillars can be readily destroyed by arsenical insecticides,† though it has yet to be ascertained to what extent it will pay to employ these substances in India.

The fact, observed by Mr. Fisher, that vigorous trees are not attacked to the same extent as trees in an unhealthy condition, is worthy of notice as being another instance of what would seem to be a very general law with insect pests.

"Cut worms" are noticed as having injured paddy, and the remedy suggested is

Bundles of cabbage, turnip, or clover are sprinkled with Paris green water and laid at intervals between the rows of the crop to be protected, but, before the plants come up, these poison the Cut worms, which are thus got rid of before the appearance of the crop which they would otherwise attack.

The scientific name of the "cut worm" is *Agrotis suffusa*. Dr. Riley of the United States is quoted to this effect:—

"The larva has a most emphatic and pernicious cutting habit. We have known it cut off large tomato plants that were over six inches in height, generally at an inch above ground. After severing one plant, the same worm would travel to other plants, and thus, in a single night, would ruin three or four. In quite hard, clayey, corn-land, each worm was found to have a smooth burrow, in which it lay hidden during the day, and to the bottom of which it could generally be traced.

"Nothing seems to come amiss to its voracious appetite. It is reported as one of the species especially destructive to corn-fields and gardens. It destroys young tomato and tobacco plants, and, in confinement, feeds with equal relish on apple and grape leaves, and has been found in a garden cutting off cypress vines; it is also one of the cotton Cut worms of the south."

CEYLON TEA IN NEW ZEALAND.

It is not going to be all smooth sailing with Mr. R. B. Taylor of Timaru, with our Exhibition representative Mr. W. Watson, and with the new Company—the Ceylon and Indian Tea Association, Limited, of Colombo and Calcutta, opened at Dunedin with

* Indian Forester, 1. c.

† See Notes on Economic Entomology, No. 2.

pure Ceylon and Indian Teas on November 5th, and which has Mr. Kenneth S. Begg as Manager. It was not to be expected that existing large dealers in China teas should stand quietly by and allow their monopoly gradually to disappear. One of the largest New Zealand tea distributing firms issued a circular in a Dunedin paper, in anticipation of the Company. It is headed "Buy Jumbo," such being the delectable brand of the firm's blends:—the Jumbo Blends at 2s and 2s 4d per lb.; and while Messrs. Nelson, Moate & Co. profess in this very document to "import more China, Indian and Ceylon teas than any wholesale distributing house south of the line," the following shows how they try to do good (?) service to Ceylon and Indian planters. They go on to say, in their precious circular, distributed all over the Colony, that their "Jumbo blends"

Are Superior and more Regular in Quality, better liquoring, and less Distasteful to those who are at all inclined to Biliousness than any original packages of Indian or Ceylon teas imported. *As all Indians and Ceylons are Sickly and most irregular in taste, we strongly recommend those who can drink them, to try these. Pure Uniform blends.*

The italics are ours. We are glad to see that Mr. Begg, in advertising the new Company, without descending to the vulgarities or the spiteful and unwarrantable attacks of Nelson, Moate & Co., relates facts in respect of China versus Indian and Ceylon teas after the following businesslike fashion:—

These Pure Ceylon and Indian teas have found such favour in the Home market that year by year they have lessened the consumption of China Teas, so that these have fallen off, according to the Customs Statistics, to less than one-half. The attempt by dealers in Chinese Teas to depreciate and cry down Ceylon and Indian Teas shows that they are afraid of this new competition here, as profits on Ceylon and Indian teas are not nearly so large as on the Chinese teas. The Ceylon and Indian teas can be guaranteed for Purity, Strength, Flavour, and Cleanliness, as they are all manufactured by machinery, under European supervision. On the other hand, the Chinese tea is made by hand, subject to all sorts of adulteration, as Europeans do not see the Tea in China until it reaches the Treaty Ports. We are selling at the Lowest Possible Prices, and as only one-half as much is required as compared with Chinese tea, the saving in using our Ceylon and Indian Teas is very considerable.

While doing their little worst to injure Ceylon and Indian teas in the estimation of the people of New Zealand, Messrs. Nelson, Moate & Co. profess to be large importers of these teas. So far as this market is concerned, we have good reason to doubt if they have been at all regular importers of teas from Colombo—they may at rare intervals have got small consignments, but we should be prepared to challenge them to prove that they have got as much as 20,000 lb. direct from Ceylon during the last ten years. Certainly after their petty but deliberate ebullition of spite in their "Jumbo" circular, all sensible people in New Zealand will look to other quarters for approved pure Ceylon teas; and teas which have carried the day in fair and open competition with "Chinas" in the mother country are not likely to be considered "sickly in taste" by the people of the "Britain in the South."

PLANTING TEA NOTES.

DEHRA DUN, Dec. 4th.—We are all busy pruning and hoeing. It is very cold now; quite a white frost in the early morning, and ice can be seen on buckets or pans of water in the early morning. Health generally good.

SONARI, Nov. 29th.—November has been an unusually good month in the way of leaf, and most gardens have made much more tea than during same month last year. Plucking will be continued well in December.

Weather much warmer than is common at this date. MANGALDAI, Dec. 2nd.—Tea season virtually closed. Most gardens in this district are behind estimate. Telegraph communication with Mangaldai opened on the 8th ultimo. November has been exceptionally warm, and has proved a good month for leaf. Still great delay in shipping tea from this ghat. Steamer calling very irregularly.

CHARALI, Dec. 2nd.—Weather still continues mild and there is every appearance of another flush or two being got before we close for the season. Pruning has been commenced on some of the gardens.

NAGRAKATA, Dec. 6th.—There has not been a drop of rain here for the last two months. The season is fast closing, many gardens having already succeeded in making their estimates. There is still a little leaf on the bushes, but another week will probably see the end of manufacture. Weather fairly cold at nights but still hot in the day time.—*Indian Planters' Gazette.*

DEPRESSION: TRADE, REVENUE AND LIFE IN MAURITIUS.

Even the better classes are not affluent, and that the trade, such as it now exists, is gradually drifting into Arab—that is Indian—hands. The Mauritians have put all their eggs into one basket, and that not a very sound one. Everything has been sacrificed to the sugarcane. Coffee and spices, tobacco, cotton, cocoa, manioc, indigo, all of which were introduced by La Bourdonnais, and all of which should thrive in this marvellous climate, have virtually disappeared. The export of sugar in 1887 was to the value of R2,31,29,949, the export of vanilla R2,36,583, the export of aloe fibre R4,46,176. These are the only products, and for everything else Mauritius depends upon outside supplies. Here, as I have the statistics before me, a few more figures may be useful. The value of the sugar exported in 1878 was R3,40,80,008. In 1887 it was only R2,31,29,949. I said in an earlier letter that Mauritius must be Indian by and by, and the following little table shows that India is already the mainstay of the Island:—

	1878.	1887.
Exports to U. K. ...	R. 78,58,767	R. 17,61,476
Do to India ...	1,05,55,272	1,39,88,469

Again the "excess of expenditure over revenue" for the last four recorded years is a handy and useful test.—

	Revenue.	Expenditure.	Deficit.
	R.	R.	R.
1884 ...	86,09,628	91,62,442	5,52,814
1885 ...	73,09,238	83,91,059	10,81,826
1886 ...	72,29,973	83,90,054	11,60,081
1887 ...	68,58,918	79,85,909	11,26,991

The official classes also feel the pinch. Mauritius is a Crown Colony, of course, and so its Civil Servants, to begin with, do not receive more than one-third of the pay drawn by their more fortunate brethren in India. At the same time they are even more affected by the silver difficulty. In the year 1878 it was imperatively necessary to set the finances of the island in order, and this was cleverly accomplished by adopting our Indian rupee currency at the rate of R10 to the pound sterling. Since then all local salaries have been drawn at the rate of R10 to the pound sterling, but in order to conciliate the officials they were allowed to remit at par as much money as they pleased to send to bona fide relations, while pensions and furlough allowances were also paid at par. Officials, however, who have joined during the last four or five years have their pensions and allowances paid at the ordinary rate of exchange. The old French Governors were remunerated at the rate of £20,000, the English Governors, until lately, drew £10,000; Sir John Pope Hennessy only draws R60,000 per annum; and it is understood that his successor, Sir Charles Lees, will draw a good deal less. Retrenchment, in fact, is the necessary order of the day all round. Mauritius used to be one of the most popular military stations in the

world—to say that it is now the most unpopular is to use a mild figure of speech. I heard of one officer who had paid £1,500 to a substitute who came here instead of him. The garrison has been cut down from three full regiments to one battalion—1st Battalion Prince of Wales's (North Staffordshire) Regiment. There is little or no exchange of hospitality between the officers of the garrison and the French Creoles—the attitude, indeed, of the Creoles just now is something like that of the Venetians towards the close of the Austrian occupation. These few facts tell you more about Mauritius than columns of descriptive writing could do.—(By a Roaming Correspondent) *Times of India*.

OUTLOOK FOR TEA, COFFEE, &c.

The worms are beginning to turn at last. A correspondent of the *Grocer* complains that the directors of many of the Indian tea companies show, to use his own words, "either wilful or foolish apathy in not placing their companies more fully before the public," and by this line of procedure, "causing the shares to be as unsaleable as a horse or a horse, or an ass, that won't go." This correspondent adds:—"And, further than this, very few of the companies have made any progress during the last ten years. They go on paying a dividend, or not, as the course of the London market (over which they have no earthly control) will admit, but hardly in any instance do they show an increase in acreage under cultivation; and as most of them have enormous uncleared ground, some of which must be most suitable for planting, if they cannot work it themselves, why do they not sell it, or lease it, or try the allotment system? Anything is better than the stagnation into which many of them have fallen."

The writer of the letter referred to has evidently been unfortunate in his selection of an investment, and he should try a company where matters are rather more lively. But there is more than a grain of truth in what he says. The way in which some of the Indian tea companies are managed in London speaks volumes for the patience and ignorance of the shareholders. Year after year these concerns go on in the good old sleepy way of twenty-five years ago, when tea was young and everybody connected with it green. That these concerns pay dividends is due more to luck than judgment, and it is strong proof of the resources of the gardens and the ability of the management in India that companies of the kind pay at all, hampered as they are by cut-of-date notions and played out ideas. Fortunately there are not many of these companies. The tea industry numbers many able and enterprising men, old and young, and the boards of some concerns are models of judicious management, although others are quite the reverse. Tea has become a great and important industry, although some people fail to recognise this and act as though they were engaged in the direction of soup kitchen. The days of experimental tea growing and fooling around are past, and a general awakening of sleepers is wanted.

The wisdom of the proposed fortnightly meeting of members of the Tea District Association is so obvious that we wonder no step of the kind has been taken before. The tea industry requires something in the nature of a permanent committee sitting in London with power to enquire into and amend all that tend to retard progress. Difficulties as they crop up require to be met promptly, and a committee possessing the confidence of the representatives of the industry in London would be able to do some actual good. We should like to have some expressions of opinion from our readers on the subject. Something of the nature of a "Tea Growers' Union" would serve the purpose and it might work as an auxiliary to the Industry Districts Association, or as a distinct organisation in harmony with it. There are numerous ways in which such a committee could be of use. Pressure might be brought to bear upon people and customs held by the majority to be hindrances to the weal of tea generally. This proposed committee of the I. T. D. A. will, we

hope, be the forerunner of some such permanent committee. Tea property and the shares of tea companies would certainly improve in value were such a committee in existence. At present competition is the ruling spirit. Union is wanted, and something more than the furthering of merely personal interests.

"We are glad to learn," says the *Produce Markets Review*, "that steps are now being taken by the Wholesale Tea Dealers' Association to lessen the time allowed for the delivery of weight-notes. The present arrangement is found to work most unsatisfactorily, as it is quite the exception to obtain weight-notes until the seven clear working days from date of purchase have expired. It is now proposed, as regards China tea, that weight notes for not less than a third of each entire parcel should be furnished to the buyer within four days from date of purchase, and the balance in a further three days. With Indian and Ceylon teas it is proposed that one half of each parcel shall be delivered to the buyer within three days of the sale, and the remainder in a further four days. Missing packages, however, to the extent of 5 per cent. in the case of Indian and Ceylon, and 10 per cent. in China teas, are to be exempted from these conditions, and are to be accepted by the buyer at the original price and prompt if tendered within fourteen days from date of contract. This, although undoubtedly a step in the right direction, does not go so far as we could wish, our contention being that no tea ought under any circumstances to be offered for sale until the packages are weighed and ready for delivery."

COFFEE.

The outlook for the coffee planting interest of Brazil does not look bright. According to the *Rio News* of Oct. 28th recently received by the mail, complaints of a great scarcity of labour were being received from all the coffee districts. Now, the country is full of able-bodied men and women who have neither property nor employment, and 200,000 immigrants have been received since the abolition of slavery; yet the three provinces in which coffee, the main source of Brazilian wealth is cultivated, are short of labourers to carry on an essential work, and short coffee crops are predicted.

We learn that the committee appointed by the Dutch Government to report on the cultivation of coffee in Dutch India has come to the conclusion that in Java and Menado the purchase price of coffee should be raised to 20fl. per pikol, with the maintenance of obligatory sale. It has also decided in favour of the principle of suppressing the compulsory growing of coffee, which is to come into operation five years after the issue of a regulation on the subject. During the five years various measures to prepare the introduction of the new system are to be taken. Many waste regions in Java are to be planted with trees, and other Government enterprises with paid labour are to be carried on to serve as models and encouragement to private enterprise. On the western coast of Sumatra the purchase price of coffee is to be raised to 25fl. per pikol, and obligatory sales to be maintained, but free choice is to be left with regard to the selection of the ground and the mode of culture, while a poll-tax is to be established as an equivalent for the increase in the price of coffee. One member of the committee was in favour of allowing the cultivation and disposal of coffee by the growers to be perfectly free, and also of cultivating the State plantations with free labour.—*H. and C. Mail*, Nov. 29th.

SUBSTITUTES FOR GUM ARABIC.—In connection with the recent disturbed state of the Soudan, and the consequent scarcity and high price of gum arabic, it is stated in a recent report, that the effects of this are now being felt in Persia, where gum is now being extensively collected from the wild Almond and other shrubs and trees, and measures are being taken to prevent the wholesale destruction of such woods. Consequent upon this, fire-wood and charcoal are expected to become scarcer and dearer in Persia, and supplies of the latter article have recently been received at Bushire from Kurrachee.—*Gardeners' Chronicle*.

GERMAN TRADE IN THE EAST.

The following extracts from an article in the *National Gazette* of Berlin headed "German Trade with Ceylon and Singapore" show how closely the press in Germany watches the development of trade. The article is written by Dr. Paul Neubauer, who has travelled several times all over the world in order to make a special study of Germany's trade relations and prospects, and the following translation has been sent to us by a Ceylon planter now at home:—

"The commercial relations which we are about to discuss embrace only a small portion of Indian trade, but they are of special importance because of the line of Imperial mail steamers. In considering the trade of the Straits Settlements and of Ceylon, the shipping tonnage of both amounting to as much as 4,229,351 tons in 1885, we would observe that Colombo not only includes the trade of Ceylon, but also the greater part of the east and west coasts of Southern India. It is connected with Europe by the N. G. Lloyd, P. and O. and M. M. steamers running to India, China and Australia, and Hamburg line, the A.-H. Lloyd and the Rubattino lines, but most especially by the B. I. lines, which has almost the monopoly of freight from the Persian Gulf to the Straits Settlements. The N. G. Lloyd have made arrangements with the B. I. by which the former are able to grant through bills of lading via Colombo to the various parts of Persia, India and Burma." (There is also a long account of shipping communications and outlets for trade with Singapore and Penang.)

"Some of the principal houses of business in Singapore are German, and there are several in the various rice ports in Bangkok, Mandalay and the Sunda Islands. In the Straits Settlements out of 1,761 Europeans 206 are Germans. It may be well to allude here to the danger which the whole European trade is exposed to by wholesale immigration of Chinese. They already outnumber the Malays and they are by no means all of the labouring class, but number many traders and even merchants among them. In the British Colonies and in Sumatra the industrial and artisan class is nearly all Chinese. Their merchants in Singapore and Penang are immensely wealthy and they bid fair before very long to acquire the whole of the intermediate trade of the adjacent territories. They hold a great deal of landed property in Singapore, especially in the commercial quarter. These are facts which should attract the serious attention of the European commercial community, as although the business done with Europe by the wealthy Chinese firms is not yet of any great extent, it soon will be, and the consequences to the mercantile community will be serious. The Germans stand to lose even more than the English and French owing to the absence of a German Bank at Singapore which would be of immense advantage as facilitating the transactions of export and import houses in Germany.

"In Colombo there are also several import German firms, among which that of the German Consul, Messrs. Freudenberg & Co., ranks as high as any of the English houses, if not higher, having a large import and port business, large oil mills, &c., &c.

"The importance of these trading centres can be clearly gathered from the foregoing remarks. The important business of both will steadily increase, as the countries round about them are opened up and in a more marked way still should the report of tropical produce; Singapore especially so and to the advantage of Germany from its proximity to the German colonies in the South Seas. As soon as the producing powers of New Guinea and the Bismarck archipelago have passed beyond the experimental stage, their communication with Singapore as an outlet will become necessary.

"The present movement of trade in Singapore represents a value of 250,000,000 dollars; in Ceylon about £91,000,000. This latter quantity is the actual trade of the island, transhipment goods representing a much higher value."

(A detailed account of merchandise imported, and exported then follows, with quantities and values.)

"The staple produce of Ceylon is, however, coffee, tea, cinnamon, cinchona, arecanuts, copra, coconut oil and

timber. In recent years there have been fluctuations in these products which call for special notice. Coffee, which several years ago represented one-third of the whole export, is now steadily declining owing to leaf-disease. Tea, however, shows the opposite results. As coffee has decreased, tea has increased, and most of the coffee estates have been converted into tea. This circumstance is especially worthy of attention by the German market. The tea itself is of excellent flavour, quite equal, if not superior, to China tea, and the tea planters of Ceylon have this advantage over the Chinese that their tea is sorted and packed for shipment on the estate itself, so that no manipulation of the article is possible. Ceylon shipments to Germany consist at present principally of coconut oil, coffee, coir &c., but little or no tea as yet."

TEA CHARGES.

Messrs. Anderson Brothers of 16 Philpot Lane issued the following circular on 6th December:—

"We regret to inform you that the Docks and Wharves have issued the following notice:—"In consequence of the great increase in the cost of labour and other expenditure resulting from the recent strike, we beg to inform you the discount at present allowed on Importers' Charges on Tea will be reduced from 20 per cent to 10 per cent, and such reduced discount will apply to all Tea arriving by ships reporting on and after the 1st January next."

TOBACCO CULTIVATION.

Now that tobacco cultivation is becoming an industry of some prominence in Ceylon, it may be well to note what is being done in other and new countries in regard to this enterprise. The last issue of the *London Chamber of Commerce Journal* says that a bright future is before Congo tobacco, both for cutting purposes and cigar making. Some samples produced by persons having no knowledge of its cultivation, and which had not been fermented, displayed a very good quality, and the leaves were very supple. A correspondent states that he received specimens from different parts of the Upper and Lower Congo country. From these he made cigars which gave excellent results as to quality and combustion—in fact leaving nothing to be desired. The Upper Congo tobaccos are superior in quality to those of the Lower Congo, especially in the fineness of the leaves, and he attributes this to the difference in the character of the soil, which is drier in the Upper Congo districts than those of the Lower, which are generally damp. In sending this glowing account of the product, the correspondent notifies the *Journal* that a company is being formed in Belgium to cultivate tobacco in the Congo Free State systematically, and under proper direction; that it will be *une affaire d'or*; and that "within two or three years all Belgian manufacturers will use the tobacco for cutting purposes and cigars."

The "Nail-less Horse Shoe Company," in which Mr. A. Ross, of Matale, has an interest, is making good progress towards launching on the London market, where it may be looked for very shortly.

Quite recently we met a gentleman, formerly manager of the Monerakaude estate in the Haputale district, Mr. Walker. He is in the enjoyment of good health, and was, when we saw him, on the point of leaving England for Switzerland, where he intended to winter with his family. He spoke in high terms of the quality of Ceylon teas, and was taking with him a quantity of the leaf, the produce of his old district, being resolved to drink no other, as well as to make its quality known to friends abroad. We gathered from him that he has not any intention of returning to Ceylon—at the same time he was very pleased to gather from us all the particulars we were able to supply, as to the great strides made by the Ceylon tea industry.

Amongst the latest registrations of new undertakings we have to notice the "The Ceylon Gem and Mining Syndicate" registered by Sydney Morse, 4, Fenchurch Avenue, E. O., with a capital of £10,400 in £1 shares.

Object, to acquire any mines mining rights or licences, or metalliferous land, and to explore, work, develop and turn to account the same. There shall not be less than three nor more than five directors, the first to be appointed by the subscribers to the Memorandum of Association. Qualification, 50 shares. Remuneration, £500, divisible. This syndicate is formed for the purpose of obtaining reliable examinations, and reports on the gem bearing capabilities of the Suffragan district in Ceylon on obtaining which it is intended to convert the syndicate into a Company with a capital sufficient for gem mining purposes. An experienced mining expert will shortly visit the island in company with Mr. E. Harding, a Ceylon planter.

The editor of an industrial journal says, "A gentleman connected with the tea trade publishes each year a table of Indian Tea Company balance-sheets. Some twenty-four companies are comprised in the statement, and they have a combined capital of £2,652,000 employed in the ownership and cultivation of 56,813 acres of tea plantations. The crop gathered is stated at 19,011,000 lb., for which the average price realised was 11.23d. per lb. After deducting cost of production an average profit of 252d. per lb. is shown. The surplus represent an average net profit of 6.87 per cent. on the investment. Twenty out of the twenty-four companies paid dividends last year, the remaining four using their surpluses to pay off debentures, and to meet interest charges. The highest dividend was 12 per cent., and the lowest $3\frac{1}{2}$ per cent. on the share capital. Seventeen companies have reserve funds, which, in the aggregate, exceed their paid-up capital by 10 per cent. Considering these favourable results it is surprising the lack of interest hitherto manifested in these concerns." Apart from the question as to 6.87 per cent being a satisfactory return for investments in India, we would remind the editor in question that the twenty-four tea gardens included in the above statement, represent probably not more than a tenth of the entire Indian tea industry. What about the annual returns on the remaining nine-tenths?

The Battalgalla Estate Company has recently been registered with a capital of £15,000 in £10 shares. Object, to acquire the Battalgalla Estate, Ceylon, and to carry on the business of tea growers, tea manufacturers and merchants. There shall not be less than three nor more than five directors. Qualification, £200. The first are E. H. Hancock, C. A. Reiss, and A. Zimmer. Remuneration to be determined in general meeting, but not to exceed £300.—"Ceylon Advertiser."

CINCHONA IN JAVA.

The report by Mr. Van Romunde, Director of the Government Cinchona Enterprise in Java, for the 3rd quarter of 1889, dated Tirtasari, 10th Oct. 1889, has reached us, and we give the following translation:—

In the latter part of July the weather continued pretty dry. During the second half of August and the month of September also few rainy days were registered. Whilst during the rainy season operations in the plantations were chiefly confined to the keeping clean of the young gardens, on the setting in of the drought the soil in the young and old plantations alike was turned up. In consequence of this stirring the plants have everywhere grown vigorously. During the past quarter only a comparatively small quantity of bark was gathered. The plantations were kept pretty thick during the dry season, in order as much as possible to protect the crown of the trees from the influence of the injurious rays of the sun. During the course of this year altogether about 500,000 pounds of bark have been gathered, of which by the end of September 449,700 half-kilograms were dispatched to Tandjong-Priok. As in the previous year caterpillars again caused considerable damage to the plants. The Nagrak establishment suffered greatly from the plague, and the insects also appeared though in less degree at Tjibeureum and Tjinjoroan, on which last-named establishment the original ledgeriana had endured a severe attack of the insects. But it

was once again chiefly the graft plantations at Tirtasari that were severely affected by caterpillars, so that even here, in order to maintain a maximum of leaf in the plantations, the gathering of bark was as good as stopped. The evil was as far as possible combated by the catching of the insects, but the plague could not be entirely checked, as the catching of the caterpillars on high branches is pretty well impracticable. In consequence of the continuous rains the seed of ledgeriana and succirubra ripened very slowly, so that up to the present it had been impossible to hold any sales of cinchona seed. Not until November and December of this year will some lots of seeds be put up for sale. On 13th June and 18th July sales of cinchona bark of the crop of 1888 were held at Amsterdam. The average prices at these sales amounted to 27.10 and 27.45 cents per half-kilogram bark. At these sales, although the bark prices fell to a hitherto unknown low point, very profitable prices were paid for ledgeriana and officialis barks,—35.21 and 37.70 cents respectively. Pharmaceutical barks in quill form also obtained good and even very high prices,—up to 91 cents per half-kilogram for succirubra. According to the detailed reports received, at the sales of 18th July, 5th September and 3rd October the unit prices calculated per half-kilogram bark and per cent quinine sulphate amounted to 7, $8\frac{1}{2}$ and $9\frac{1}{2}$ cents.

The total number of plants in the Government Gardens at the end of the 3rd quarter of 1889 amounted to 3,293,300. In the nurseries there were:—1,205,000 ledgeriana (including 15,000 grafts) and 180,000 succirubra: total 1,385,000. In the open there were:—1,220,000 ledgeriana (including 225,000 cuttings and grafts and exclusive of the more or less 3,000 original ledgeriana) 300 calisaya and baskarliana, 618,000 succirubra and calonera, 68,500 officialis, and 500 lancifolia: total 1,908,300.

THE BRITISH EAST AFRICAN COMPANY: AT THE ROYAL SCOTTISH GEOGRAPHICAL SOCIETY.

Last night the inaugural address of the session was delivered in the Synod-Hall, Edinburgh, to the members of the Royal Scottish Geographical Society by Sir Lewis Pelly, K.C.B., M.P., Dr. Murray, of the "Challenger" expedition, presided in the absence of the Duke of Argyll. There was a large attendance.

Sir LEWIS PELLY in the course of his remarks referred to the operations of the British East Africa Company. He said that a most gratifying feature of the active explorations of the company's officers was found in the peacefulness of their progress and the good-will which they had everywhere succeeded in winning from the natives by their method of dealing with the various chiefs and tribes. The first year's progress in opening the interior to civilizing influences, with a staff merely initial and a base of operations limited to a line of coast (about 150 miles long) promised large and rapid results. Now that the company's sea base had been extended some hundred of miles further to the north, and that the company was stretching itself to a more comprehensive grasp of its great work westward, the extension of British influence was free to the confines of the Congo independent State beyond the Albert Nyanza and northwards. Much had been done during the few months of the company's existence in a practical direction at Mobassa and elsewhere by the construction of a pier, a lighthouse, a short line of rail, and other ordinary appliances of civilization. The first strand of a railway (about 40 miles in length), intended to connect the port of Mombassa with Lake Victoria Nyanza, was being sent out from England. The coast line from Mombassa to Kipini was being connected by telegraph, and road arrangements had been completed under which Mombassa was connected with the sea cable of Sir John Pender's company, and thus placed in direct communication with London, Aden, and Bombay. One or two small coasting steamers had been ordered for feeding commerce. A shallow steam craft would ply

on the river Tana, while the British India Steam Navigation Company would run a fortnightly line of swift mail steamers between London, Mombassa, and other ports. Caravans would continue to traverse the interior in all directions, surveying the country, establishing convenient stations, prosecuting friendly intercourse with the tribes, and examining by experts the mineralogical features of the higher lands. Mr. Stanley had now discovered that Lake Victoria Nyanza stretched far away to the south-west of what was supposed to be its southern limit. It reached 270 miles long and covered an area of 27,000 square miles. Moving southward from the inland point of the East Africa Company's southern limit, we passed along the Lake Tanganyika, and arrived at the region so beneficially developed by the African Lakes Company, which was originally organized as a lay section of the missionary societies. This company, however, under the guidance of some disinterested Scottish merchants, though enjoying no charter at all, had pushed British trade and interests and had supported British missions over all that area which was sacred to the name of Livingstone. The company succeeded in developing regions of East Central Africa between the Zimbezi River and the Tanganyika Lake. It constructed a practicable road between Lakes Nyassa and Tanganyika, another road round the rapids of the Shiré River, and it launched steamers on the waters of the Nyassa. The influence of the company had been wholly for good, giving employment to natives, excluding spirits and firearms, strengthening the hands of the missionaries, and tending to check intertribal strife and the slave trade. It was possible that this excellent little company might now be merged in the larger association to which the British Government had within the past few weeks granted a charter under the name of the British South Africa Company. This latter company embraced in its operations the immense area lying between the Upper and Middle Zambesi on the north and the Crown colony of British Bechuanaland and Transvaal border on the south. A glance at the map showed that the backbone of the African Continent was a line protracted in a north-east and south-west direction along the high level lake region from South Africa to the Red Sea. It might be objected that it was a far cry from the Cape to Cairo. So it was, but therein lay the problem to be solved. Already there were railways from Cape Town and Port Elizabeth to Kimberley, and a line was projected and the money forthcoming for an extension to Shoshong and beyond. While they were assembled there it was quite possible that arrangements might be in contemplation for connecting Lakes Nyassa and Tanganyika, with the Shoshong terminus. These lakes already had cognizance of steam vessels. The Germans and British might be counted on to connect Tanganyika with Victoria Nyanza and to place steamers on the Victoria itself thus debouching on the valley of the Nile, and stretching out on the east to meet the rail to the Port of Mombassa, and on the west towards the river transport of the Congo basin and the railway which would soon bridge the navigable rapids of the lower reaches between Matadi and Stanley Pool. (Cheers).—London Times, Nov. 29th.

CEYLON COTTON: BROKING REPORTS.

We are indebted to Messrs. Darley, Butler & Co. for brokers' reports (two on Sea Island and one on Egyptian) and sales note of part showing how Mr. Blackett's cotton is selling at home. We are sure they will be full of interest as well as encouragement to many in our midst:—

REPORT ON 7 BALES COTTON RECEIVED PER "DEUCALION" (STEAMER) AT COLOMBO.

London, Oct. 31st.

SI MG.—Value about 14d, excellent cotton, fine, long, strong staple. If this cotton can be produced clean and free from stain it will almost equal the best American Sea Island Cotton, and be worth 15d to 20d per lb. It should be picked in dry weather if possible. It is longer and stronger, and finer than

Florida Sea Island which sells at about 14d per lb. A sample of this class of cotton is herewith forwarded to show the cleanliness spinners like.

There is a good and regular demand for this class of cotton, and all that can be produced would find a ready market. We should judge from this sample that the climate and soil of Ceylon is adapted to grow a Sea Island cotton of the very finest quality.

REPORT AND VALUATION OF 6 BALES COTTON PER "DEUCALION" (S.)

Marks.	Quantity.	Description.	General Remarks.	Staple.	Value per lb.	Classification.
S. I. M. G.	2	Ceylon	<i>Sea Island.</i> Bright in colour, a little leaf, & broken seed.	Very long and fine.	14d	Nominally.
S. I. H. G.	1	do	Slightly brown in colour, very little leaf.	do	13½d to 14d	do
E. W. H. G.	1	do	<i>Egyptian.</i> Generally white, but rather spotted, very little leaf.	do	6½d to 7d	do
E. B. M. G.	1	do	Brown in colour, a little leaf, & broken seed.	Rather short.	6½d to 6¾d	do
E. W. M. G.	1	do	Slightly spotted, a little leaf & broken seed.	Short & rather coarse.	6½d to 7d	do

6 bales.
London, 17th October 1889.

Nov 20 1889	SI	2 Bales	Cotton	J Blackett	Mary Hough	
"	SI	1 Bale	"	"	"	12½d
"	KG	3 Bales	Received	6 bales	"	

To J Blackett, Esq, Ceylon,
London, November 22nd, 1889

Mr. D. Joseph of Matale, in sending an advertisement which appears elsewhere, favours us with a sample of cotton and writes:—

Enclosed you will find sample of the Fiji cotton grown by me and from which the seeds now advertised was giuned. My small venture in cotton cultivation is, so far, a splendid success, and I believe that Fiji cotton could be cultivated to advantage in Matale, notwithstanding pests, adverse seasons and the criticisms of hasty writers.

THE CHINESE TEA GUILD AND INDIAN COMPETITION.

The N. O. Daily News translates the following from the Shen-pao:—The Taotai has received the following report from ten Chinese gentlemen, forming the Committee of the Tea Guild, giving their suggestions towards the revival of the Chinese tea-trade now suffering severely from Indian and other competition. It was called for by the Taotai on 11th November, in pursuance of an order from the Viceroy Li Hung-chang, received in consequence of instructions from the Tsung-li Yamén dated 30th September. The Yamén, which had already directed the Viceroy's attention to this matter a year before, is now desirous of obtaining the opinion of the leading teamen with regard to a recent report of the Commissioner of Customs at Tamsui to the Governor of Formosa. In the latter report the Commissioner had ascribed the falling-off in the Formosan tea-export to two causes; the adulteration of the leaf, sometimes t

the extent of ten per cent, with extraneous substances, (principally, however, tea stalks) and the excessive amount of inland duty levied. The teamen's report is as follows:—

They think the complaint of adulteration is not justified by the facts. They have some personal experience of the preparation of the teas which they sell to foreigners at Shanghai, Kiukiang, or Hankow. These are the *red teas* (i. e., black teas) of Hunan, Hupeh, and Kiangsi, the green tea of Anhui, and the Pingsuey of Chékiang; but on the Foochow teas they have no information to give. Leaving, therefore, the Foochow Teas to be reported on by the teamen of that port, they think they can safely say of the other kinds that, whatever may have been the case ten years ago, at present adulteration practically does not exist. At that time some Chékiang Pingsueyes were falsified with siftings, and with little pellets of rice paste; but the strenuous efforts made by the Guild to check this abuse, combined with the present abundance and cheapness of the supply, have combined to suppress adulteration, and any defects in quality now-a-days can be only caused by original want of flavour of the pure article and bad methods of preparing it for the market. The rigorous scrutiny, moreover, to which every chop is subjected by the foreign buyers at the Treaty ports would make any attempt at imposition so hopeless, that no teaman would think it worth his while, even if his conscience would consent to it, to make such attempt. As for tea siftings they have their own buyers, the brick-tea merchants; and tea-stalks find a profitable market in the interior.

The real cause of the decline in the tea-trade is therefore to be sought not in any imaginary adulteration of tea in China, but in the excessive inland and export duties levied there, and in defects in growing and preparing; and the following six suggestions are put forward by the Guild as the remedy for that decline.

1.—Increased care in growing. In China, the tea generally grows on the slopes of hills. This ground is hard and cold, and the plant has to make a greater effort to grow on such a soil than in the warm and loose-soiled plains in which it is cultivated in other countries. But in those countries, although its leaf is softer, the juice contained in it is far thinner and less flavoured than what is distilled from the Chinese tea plant. Let the up-country growers, who are, sad to relate, in many instances abandoning their tea-gardens on the hills, owing to the smallness of the prices which are offered to them for the product, take heart, and they will still produce an article that can hold its own against any in the world. Let them take advantage of the winter season to well loosen the soil, and fertilise it with ash-manure, and they will have a fine crop by next season, which will richly repay them for all their trouble.

2.—There should be no delay in picking the various crops at their seasons. In China these are three, called respectively first, second, and third spring crops. So little attention has been paid of late years to this important point, that the market has been flooded with large coarse old leaves, while the tender fresh young ones, the best of the tea harvest, have been conspicuous by their absence. Mr. Huang, the late Prefect of I-ning Ohow, in Kiang-si, was so well aware of the advantages to be got by timely picking that he ordered all the growers in his jurisdiction to pick the young new season's leaves at least ten days' before the spring rains, and enjoined the greatest care in the preparation of the tea for the market. In fact, this Prefect went so far as to invite the buyers of tea to inform him of any violation of these injunctions, so that he might inflict punishment on the offenders. Not one tea-grower dared disobey, and the consequence was a splendid crop of Ningehows last year, which fetched excellent prices.

3.—In firing the tea, charcoal should always form the fuel to prevent any possibility of a smoky taste being imparted. The foreign *chaasze* is now grown very fastidious, and tea fired by wood fires meets with either rejection or a cut. The officials should impress on the up-country growers, by every possible means,

the folly of attempting to economise in such a manner as using wood instead of charcoal for this purpose.

4.—Machinery should be used in preparing tea. At present in China human labour only is employed, which is a most expensive and cumbersome arrangement.

5.—Likin and other inland charges should be reduced. Besides taxes levied on the growers at the place of production, under a variety of names, varying in different provinces, likin is collected at every barrier, and the tea, which now is only two-fifths of its former value, is taxed as heavily as in the prosperous old days; which is very discouraging to those who deal in it in the interior.

6.—Export duty should be diminished. Indian and Ceylon teas pay neither likin nor export duty, and in Japan the export duty is only \$1 per 100 catties. In China the old Canton tariff was Tls. 2½ per 100 catties. The trade was then a flourishing one; 100 catties was worth Tls. 50 or more, and could well bear a tax of five per cent. The case is very different now when most teas only fetch 8 or 9 taels per 100 catties a price of Tls. 30 being rarely obtainable. The present export duty comes to about 25 per cent all round, which is certainly excessive. The unfortunate teaman has besides to pay on every 100 catties from 4 to 7 taels for boxes, firing-charcoal, coolie-hire, transport and other concomitant expenses. A graduated scale of export duties should be introduced, instead of the present system of indiscriminately taxing all teas two taels and a half per 100 catties.

The Tea Guild are of opinion that in the adoption of the reforms they have proposed is to be found the remedy for the present depression; and they confidently maintain that if these changes are introduced not only will the merchants themselves be benefited, but the Government will be rewarded for its efforts on their behalf, by the largely increased receipts accruing from the enlarged volume of the trade.

DEALERS V. GAMBLERS IN MINCING-LANE.

A Market, according to old-fashioned ideas, is a place where commodities are bought and sold; but of late years produce markets have largely followed the bad lead of the Stock Exchange, and become to a great extent centres of mere gambling. The evil has been largely intensified since the establishment of the Produce Clearing House and the terminal market arrangements, &c. By these a spirit of gambling has been induced among small dealers, particularly on the Continent, who operate on the remote chance of an easy profit; but the frequent consequent collapses have proved most detrimental to the wholesale dealers here, who now find this trade too hazardous, and are really dubious of trusting anybody. Brokers, financial houses, and others who would be less of a pest to commerce, if they had kept in their proper sphere, the turf, have done very much to disturb legitimate arrangements, and we have by no means seen the end of the mischief that these harpies will effect.

These observations are suggested by an article which we reproduce from the *Financial News*. We are not concerned to defend Mr. O'Donoghue; for all we know to the contrary, he deserves the satire with which the *Financial News* has treated him. This, however, we do know, that the article in our contemporary is of a very "bullish" tendency, and that there is, or was up to the end of last week, a strong bull account open in coffee on the Produce Clearing-house. We should like to enquire, was the article inspired by or in any way due to interest in this bull movement? It is very generally stated that the great fortune Mr. Marks has made out of the *Financial News* has been largely augmented by success in kindred departments of business, and we imagine he looks with a kindly eye on the Produce Clearing-house, inasmuch as he was an original allottee of 100 shares in that company.

We observe that of late much attention has been paid in the columns of the *Financial News* to tea, coffee and other commodities which are used as gaming counters in the Produce Clearing-house, and this

is likely to increase the undesirable Capel-court methods which are so injurious to the community when, applied to food products, although, of course, the successful gamblers reap a rich harvest.

We would next ask, is it compatible with the interests of coffee dealers that coffee values should be largely at the mercy of sets of gamblers by whose tricks and dodges business is severely harassed? And would dealers be well advised to discriminate against those brokers (it is unnecessary to name them here) who for the sake of extra commissions, aid and abet a system which is most prejudicial to legitimate business.—*Grocers' Gazette*

COFFEE AND CONSCIENCE.

(From the *Financial News*.)

"Strict integrity in business is always respected and admired by the world, and the most censorious critic could hardly refuse his praise to a man who retires from trade because he can no longer conduct it profitably without doing violence to his conscience. Such a man, apparently, is Mr. Joseph J. O'Donohue, the great coffee dealer of New York, who has given up business and resigned from the Coffee Exchange because he is disgusted with the element of gambling that has been introduced into it. In an outburst of virtuous indignation, he went so far as to say that the men dealing upon the Exchange were 'little better than confidence operators and bunco steerers.' He said, further, that he 'could no longer associate himself with a business which had for its ultimate end the robbery of the poor man'; and, altogether, the merchant took the highest moral grounds against gambling in food products, and particularly in coffee. He makes the important statement that the American people are paying £8,000,000 more for their coffee than they ought to pay—a kind of allegation that might lead one to suppose that Mr. O'Donohue is in sympathy with the bears, were it not for the fact that he proclaims himself against the manipulators of coffee, either bulls or bears. Mr. O'Donohue is particularly hard upon the New York Coffee Exchange, which he holds responsible for the evils that have driven him from business. The Brazil growers, he says, work the market for their own benefit, and the poor man is, in the end, the sufferer. 'So,' concludes the honest dealer, 'I go out of business on purely conscientious scruples.' Curtain! All this leads us to reflect upon the efficacy of business reverses to induce exceptional business morality. It may be remembered that in July last the *Financial News*, in the course of an article entitled 'A Gamble in Coffee,' mentioned the fact that a New York jobber had come to London openly boasting that he was 'going to bust up the Mincing-Lane coffee market.' This jobber was Mr. Joseph J. O'Donohue, the moral merchant of New York. He certainly did his best to 'bust up' the market, and his bear operations were of such magnitude as to attract considerable attention, and to cause no little consternation. But Mincing-lane still exists, and Mr. O'Donohue has retired. He found it difficult to keep down the price of coffee when the present crop is calculated to be a couple of million of bags below the average and he has, therefore, shown his sense in abandoning the field of speculation. The president of the New York Coffee Exchange is unkind enough to say that the reason Mr. O'Donohue is disgusted with the Exchange is because the members did not elect him president; but, however that may be, Mincing-lane may be relieved to learn that the New York jobber who came over to 'bust up' their market has retired into private life."

THE TEA TRADE: ALL ABOUT BLENDING.

The enterprising grocer of today has a way of including among his wares many drugs, medicines, &c., which in more old-fashioned times were only to be bought at a chemist's shop, and no doubt many readers of the *Chemist and Druggist* have smarted under such competition. Now a chemist as a rule can hardly retaliate by importing a grocery department bodily into his shop, but that he can and often does add sensibly to his profits by retailing tea may be proved, if proof were needed, by a letter which appeared in the *Chemist and*

Druggist of September 21st, 1889, from a "Country Chemist," who in a few years blended and retailed 7,000l worth of tea.

It is of course impossible in an article to teach all the ins and outs of the tea trade, with its multitudinous kinds and qualities of tea; but it is quite possible by a few hints and suggestions to enable a chemist who really intends to do a tea trade to compete, and compete successfully, with the average grocer or tea dealer, even though he may profess to make tea his constant study, and to retail "scientific blends" at "Mincing Lane prices." Too often tea purchased at a chemist's shop reminds one only too forcibly of other draughts to be obtained in the same quarter; but there is no reason at all why this should be the case if only proper care and attention are bestowed, and the principle acted on that whatever is worth doing at all is worth doing well.

A chemist may buy his tea in any of three ways. First, ready blended and packed in ½-lb., ¾-lb., and 1-lb. packets (lead or paper), to retail at 2s, 2s 6d or 2s 8d, and 3s per lb., and sometimes to retail at 1s 8d per lb. Second, ready blended, but to be put up in packets by the retailer, who will of course use his own discretion as to profits. No instructions are necessary in these cases save a few suggestions as to material for packets below.

If, however, in the third place, the chemist elects to buy original packages from the wholesale dealer, and to blend and pack for himself, he will require to know the kinds of tea to buy, the proportions to mix, and the prices to pay.

There is a uniform duty of 6d per lb. on all kinds and qualities of tea, and no licence is required for selling. Four prices should be fixed upon for retailing—1s 4d, 1s 8d, 2s, and 2s 6d or 2s 8d per lb., though it will be found that the demand for tea over 2s per lb. is not large, and that for tea over 1s 8d per lb. is in many districts decreasing. The 1s 4d tea will be a blend of China and Assam (Indian), for, though occasionally Ceylons can be bought at sufficiently low prices to use in this blend, it is quite the exception. The other three blends should consist of Ceylon and Assam, or Ceylon pure and simple (care being taken to describe blends of Ceylon and Assam as "Ceylon blends selected from choice Ceylon and Indian growth," &c.), though three other more old-fashioned blends of China and Assam are given in case it may be desired to have both on sale. The proportions given below for mixing are purposely simple, and arranged so that it may be necessary to buy as few packages of tea as possible, but they will, with reasonable care in buying, give thoroughly good blends and require a good deal of beating. The prices given are, as far as possible, average prices for useful teas, lowest grades being, of course, most liable to fluctuation, leaf Assam, for example, having recently been obtainable as low as 6d per lb. in bond.

(a) China and Assam blend, to sell at 1s 4d per lb.

Costing about
s. d.

Equal parts { Leaf Kaisow 0 6
 { Leaf Assam 0 8

Blended costs 7d per lb., and 6d duty leaves 3d profit gross.

(b) Ceylon blend, to sell at 1s 8d per lb.

Costing about
s. d.

Equal parts { Leaf Assam 0 8
 { Leaf Ceylon 0 10
 { Assam Pekoe 1 0

Blended costs 10d per lb., and 6d duty leaves 4d profit gross.

(c) Ceylon blend, to sell at 2s per lb.

Costing about
s. d.

Equal parts { Assam Pekoe 1 0
 { Ceylon Pekoe 1 0

Blended costs 1s per lb., and 6d duty leaves 6d profit gross.

[A "self-drinking" Ceylon can often be bought at about 1s that will not require blending with Assam, but as Ceylon fluctuates rather violently it would not always be easy to keep the tea the same, and it will be better in practice to blend with Assam.]

the extent of ten per cent, with extraneous substances, (principally, however, tea stalks) and the excessive amount of inland duty levied. The teamen's report is as follows:—

They think the complaint of adulteration is not justified by the facts. They have some personal experience of the preparation of the teas which they sell to foreigners at Shanghai, Kiukiang, or Hankow. These are the *red teas* (i. e., black teas) of Hunan, Hupeh, and Kiangsi, the green tea of Anhui, and the Pingsuey of Chèkiang; but on the Foochow teas they have no information to give. Leaving, therefore, the Foochow Teas to be reported on by the teamen of that port, they think they can safely say of the other kinds that, whatever may have been the case ten years ago, at present adulteration practically does not exist. At that time some Chèkiang Pingsueyes were falsified with siftings, and with little pellets of rice paste; but the strenuous efforts made by the Guild to check this abuse, combined with the present abundance and cheapness of the supply, have combined to suppress adulteration, and any defects in quality now-a-days can be only caused by original want of flavour of the pure article and bad methods of preparing it for the market. The rigorous scrutiny, moreover, to which every chop is subjected by the foreign buyers at the Treaty ports would make any attempt at imposition so hopeless, that no teaman would think it worth his while, even if his conscience would consent to it, to make such attempt. As for tea siftings they have their own buyers, the brick-tea merchants; and tea-stalks find a profitable market in the interior.

The real cause of the decline in the tea-trade is therefore to be sought not in any imaginary adulteration of tea in China, but in the excessive inland and export duties levied there, and in defects in growing and preparing; and the following six suggestions are put forward by the Guild as the remedy for that decline.

1.—Increased care in growing. In China, the tea generally grows on the slopes of hills. This ground is hard and cold, and the plant has to make a greater effort to grow on such a soil than in the warm and loose-soiled plains in which it is cultivated in other countries. But in those countries, although its leaf is softer, the juice contained in it is far thinner and less flavoured than what is distilled from the Chinese tea plant. Let the up-country growers, who are, sad to relate, in many instances abandoning their tea-gardens on the hills, owing to the smallness of the prices which are offered to them for the product, take heart, and they will still produce an article that can hold its own against any in the world. Let them take advantage of the winter season to well loosen the soil, and fertilise it with ash-manure, and they will have a fine crop by next season, which will richly repay them for all their trouble.

2.—There should be no delay in picking the various crops at their seasons. In China these are three, called respectively first, second, and third spring crops. So little attention has been paid of late years to this important point, that the market has been flooded with large coarse old leaves, while the tender fresh young ones, the best of the tea harvest, have been conspicuous by their absence. Mr. Huang, the late Prefect of I-ning Chow, in Kiang-si, was so well aware of the advantages to be got by timely picking that he ordered all the growers in his jurisdiction to pick the young new season's leaves at least ten days' before the spring rains, and enjoined the greatest care in the preparation of the tea for the market. In fact, this Prefect went so far as to invite the buyers of tea to inform him of any violation of these injunctions, so that he might inflict punishment on the offenders. Not one tea-grower dared disobey, and the consequence was a splendid crop of Ningehow's last year, which fetched excellent prices.

3.—In firing the tea, charcoal should always form the fuel to prevent any possibility of a smoky taste being imparted. The foreign *chaasze* is now grown very fastidious, and tea fired by wood fires meets with either rejection or a cut. The officials should impress on the up-country growers, by every possible means,

the folly of attempting to economise in such a manner as using wood instead of charcoal for this purpose.

4.—*Machinery* should be used in preparing tea. At present in China human labour only is employed, which is a most expensive and cumbersome arrangement.

5.—Likin and other inland charges should be reduced. Besides taxes levied on the growers at the place of production, under a variety of names, varying in different provinces, likin is collected at every barrier, and the tea, which now is only two-fifths of its former value, is taxed as heavily as in the prosperous old days; which is very discouraging to those who deal in it in the interior.

6.—Export duty should be diminished. Indian and Ceylon teas pay neither likin nor export duty, and in Japan the export duty is only \$1 per 100 catties. In China the old Canton tariff was Tls. 2½ per 100 catties. The trade was then a flourishing one; 100 catties was worth Tls. 50 or more, and could well bear a tax of five per cent. The case is very different now when most teas only fetch 8 or 9 taels per 100 catties a price of Tls. 30 being rarely obtainable. The present export duty comes to about 25 per cent all round, which is certainly excessive. The unfortunate teaman has besides to pay on every 100 catties from 4 to 7 taels for boxes, firing-charcoal, coolie-hire, transport and other concomitant expenses. A graduated scale of export duties should be introduced, instead of the present system of indiscriminately taxing all teas two taels and a half per 100 catties.

The Tea Guild are of opinion that in the adoption of the reforms they have proposed is to be found the remedy for the present depression; and they confidently maintain that if these changes are introduced not only will the merchants themselves be benefited, but the Government will be rewarded for its efforts on their behalf, by the largely increased receipts accruing from the enlarged volume of the trade.

DEALERS V. GAMBLERS IN MINCING-LANE.

A Market, according to old-fashioned ideas, is a place where commodities are bought and sold; but of late years produce markets have largely followed the bad lead of the Stock Exchange, and become to a great extent centres of mere gambling. The evil has been largely intensified since the establishment of the Produce Clearing House and the terminal market arrangements, &c. By these a spirit of gambling has been induced among small dealers, particularly on the Continent, who operate on the remote chance of an easy profit; but the frequent consequent collapses have proved most detrimental to the wholesale dealers here, who now find this trade too hazardous, and are really dubious of trusting anybody. Brokers, financial houses, and others who would be less of a pest to commerce, if they had kept in their proper sphere, the turf, have done very much to disturb legitimate arrangements, and we have by no means seen the end of the mischief that these harpies will effect.

These observations are suggested by an article which we reproduce from the *Financial News*. We are not concerned to defend Mr. O'Donoghue; for all we know to the contrary, he deserves the satire with which the *Financial News* has treated him. This, however, we do know, that the article in our contemporary is of a very "bullish" tendency, and that there is, or was up to the end of last week, a strong bull account open in coffee on the Produce Clearing-house. We should like to enquire, was the article inspired by or in any way due to interest in this bull movement? It is very generally stated that the great fortune Mr. Marks has made out of the *Financial News* has been largely augmented by success in kindred departments of business, and we imagine he looks with a kindly eye on the Produce Clearing-house, inasmuch as he was an original allottee of 100 shares in that company.

We observe that of late much attention has been paid in the columns of the *Financial News* to tea, coffee and other commodities which are used as gambling counters in the Produce Clearing-house, and this

is likely to increase the undesirable Capel-court methods which are so injurious to the community when, applied to food products, although, of course, the successful gamblers reap a rich harvest.

Would next ask, is it compatible with the interests of coffee dealers that coffee values should be largely at the mercy of sets of gamblers by whose tricks and dodges business is severely harassed? And would dealers be well advised to discriminate against those brokers (it is unnecessary to name them here) who for the sake of extra commissions, aid and abet a system which is most prejudicial to legitimate business.—*Grocers' Gazette*

COFFEE AND CONSCIENCE.

(From the *Financial News*.)

"Strict integrity in business is always respected and admired by the world, and the most censorious critic could hardly refuse his praise to a man who retires from trade because he can no longer conduct it profitably without doing violence to his conscience. Such a man, apparently, is Mr. Joseph J. O'Donohue, the great coffee dealer of New York, who has given up business and resigned from the Coffee Exchange because he is disgusted with the element of gambling that has been introduced into it. In an outburst of virtuous indignation, he went so far as to say that the men dealing upon the Exchange were 'little better than confidence operators and bunco steers.' He said, further, that he 'could no longer associate himself with a business which had for its ultimate end the robbery of the poor man'; and, altogether, the merchant took the highest moral grounds against gambling in food products, and particularly in coffee. He makes the important statement that the American people are paying £6,000,000 more for their coffee than they ought to pay—a kind of allegation that might lead one to suppose that Mr. O'Donohue is in sympathy with the bears, were it not for the fact that he proclaims himself against the manipulators of coffee, either bulls or bears. Mr. O'Donohue is particularly hard upon the New York Coffee Exchange, which he holds responsible for the evils that have driven him from business. The Brazil growers, he says, work the market for their own benefit, and the poor man is, in the end, the sufferer. 'So,' concludes the honest dealer, 'I go out of business on purely conscientious scruples.' Curtain! All this leads us to reflect upon the efficacy of business reverses to induce exceptional business morality. The president of the New York Coffee Exchange is unkind enough to say that the reason Mr. O'Donohue is disgusted with the Exchange is because the members did not elect him president; but, however that may be, Mincing-lane may be relieved to learn that the New York jobber who came over to 'bust up' their market has retired into private life."

THE TEA TRADE: ALL ABOUT BLENDING.

The enterprising grocer of today has a way of including among his wares many drugs, medicines, &c., which in more old-fashioned times were only to be bought at a chemist's shop, and no doubt many readers of the *Chemist and Druggist* have smarted under such competition. Now a chemist as a rule can hardly retaliate by importing a grocery department bodily into his shop, but that he can and often does add sensibly to his profits by retailing tea may be proved, if proof were needed, by a letter which appeared in the *Chemist and*

Druggist of September 21st, 1889, from a "Country Chemist," who in a few years blended and retailed 7,000*l* worth of tea.

It is of course impossible in an article to teach all the ins and outs of the tea trade, with its multitudinous kinds and qualities of tea; but it is quite possible by a few hints and suggestions to enable a chemist who really intends to do a tea trade to compete, and compete successfully, with the average grocer or tea dealer, even though he may profess to make tea his constant study, and to retail "scientific blends" at "Mincing Lane prices." Too often tea purchased at a chemist's shop reminds one only too forcibly of other draughts to be obtained in the same quarter; but there is no reason at all why this should be the case if only proper care and attention are bestowed, and the principle acted on that whatever is worth doing at all is worth doing well.

A chemist may buy his tea in any of three ways. First, ready blended and packed in $\frac{1}{2}$ -lb., $\frac{3}{4}$ -lb., and 1-lb. packets (lead or paper), to retail at 2s, 2s 6d or 2s 8d, and 3s per lb., and sometimes to retail at 1s 8d per lb. Second, ready blended, but to be put up in packets by the retailer, who will of course use his own discretion as to profits. No instructions are necessary in these cases save a few suggestions as to material for packets below.

If, however, in the third place, the chemist elects to buy original packages from the wholesale dealer, and to blend and pack for himself, he will require to know the kinds of tea to buy, the proportions to mix, and the prices to pay.

There is a uniform duty of 6d per lb. on all kinds and qualities of tea, and no licence is required for selling. Four prices should be fixed upon for retailing—1s 4d, 1s 8d, 2s, and 2s 6d or 2s 8d per lb., though it will be found that the demand for tea over 2s per lb. is not large, and that for tea over 1s 8d per lb. is in many districts decreasing. The 1s 4d tea will be a blend of China and Assam (Indian), for, though occasionally Ceylons can be bought at sufficiently low prices to use in this blend, it is quite the exception. The other three blends should consist of Ceylon and Assam, or Ceylon pure and simple (care being taken to describe blends of Ceylon and Assam as "Ceylon blends selected from choice Ceylon and Indian growth," &c.), though three other more old-fashioned blends of China and Assam are given in case it may be desired to have both on sale. The proportions given below for mixing are purposely simple, and arranged so that it may be necessary to buy as few packages of tea as possible, but they will, with reasonable care in buying, give thoroughly good blends and require a good deal of beating. The prices given are, as far as possible, average prices for useful teas, lowest grades being, of course, most liable to fluctuation, leaf Assam, for example, having recently been obtainable as low as 6d per lb. in bond.

(a) China and Assam blend, to sell at 1s 4d per lb.

		Costing about
		s. d.
Equal parts	{ Leaf Kaisow	0 6
	{ Leaf Assam	0 8

Blended costs 7d per lb., and 6d duty leaves 3d profit gross.

(b) Ceylon blend, to sell at 1s 8d per lb.

		Costing about
		s. d.
Equal parts	{ Leaf Assam	0 8
	{ Leaf Ceylon	0 10
	{ Assam Pekoe	1 0

Blended costs 10d per lb., and 6d duty leaves 4d profit gross.

(c) Ceylon blend, to sell at 2s per lb.

		Costing about
		s. d.
Equal parts	{ Assam Pekoe	1 0
	{ Ceylon Pekoe	1 0

Blended costs 1s per lb., and 6d duty leaves 6d profit gross.

[A "self-drinking" Ceylon can often be bought at about 1s that will not require blending with Assam, but as Ceylon fluctuates rather violently it would not always be easy to keep the tea the same, and it will be better in practice to blend with Assam.]

(d) Ceylon, to sell at 2s 6d or 2s 8d per lb.—finest tea—can be bought in chests or half-chests at 1s 5d or 1s 6d and duty, that will not require blending. It must be a rich, thick liquoring tea, with quality, that can be drunk by itself.

(e) China and Assam blend, to sell at 1s 8d per lb.
Costing about

	s.	d.
2 parts Soomoo, or Saryune Kaisow, or Ningchow Moning	...	0 10
1 part leaf Assam	...	0 8
1 part Assam Pekoe	...	1 0

Blended costs 10d per lb., and 6d duty leaves 4d profit gross.

(f) China and Assam blend, to sell at 2s per lb.

	s.	d.
2 parts Soomoo, or Saryune Kaisow, or Ningchow Moning	...	0 10
1 part Assam Pekoe	...	1 0
1 part Assam Pekoe	...	1 4

Blended costs 1s per lb., and 6d duty leaves 6d profit gross.

(g) China and Assam blend, to sell at 2s 6d or 2s 8d per lb.

	s.	d.
Equal parts { Fine Ningchow Moning,	...	1 6
{ or Chingwo Kaisow	...	1 6
{ Assam Pekoe	...	1 4

Blended costs 1s 11d per lb., and 6d duty leaves 7d or 8d profit gross.

In writing for samples, a few stamps may be enclosed to cover cost, as first orders will be small. The terms on which a wholesale dealer sells tea are three months' credit with satisfactory references, and cash for duty on delivery. If references are not given the market terms are discounted for ninety days at 5 per cent per annum on tea, duty of course net. To begin with as small a stock as possible, first order for blends *a*, *b*, *c*, and *d* may be as follows:—One-half chest Kaisow at 6d; one chest leaf Assam (Souchong or Pekoe Souchong), at 8d; one chest Assam Pekoe at 1s, and if possible one half-chest each Ceylon leaf (Souchong or Pekoe Souchong) at 10d; Ceylon Pekoe at 1s, and Ceylon Pekoe "self-drinking" tea at 1s 5d to 1s 6d. This, with duty 6d per lb., involves an outlay of about 30l, and if the thing is to be done in such a way as to compete with neighbouring grocers and tea dealers it cannot well be attempted on a smaller scale.

If blends *a*, *e*, *f*, and *g* are used, the minimum quantity to be ordered (in addition to the half-chest Kaisow at 6d, and chest Assam at 8d, for use in the 1s 4d blend) will be: Two half-chests Soomoo or Saryune Kaisow at 10d, one chest Assam Pekoe at 1s, one chest Assam Pekoe at 1s 4d, and one half-chest Ningchow Moning or Chingwo Kaisow at 1s 6d.

China tea is mostly imported in half-chests (56 to 60 lb. net), Assam in chests (90 to 100 lb. net) and Ceylon in chests as Assam, or half-chests (of about 50 lb. net). In some parts of England a great deal of Scented Caper and Scented Orange Pekoe—especially the former—is used, the consumption being large in the West, Midlands, and North of England. These teas are bought in 20-lb. boxes, from 7d to 1s 6d or more per lb., and may be kept in stock for use where required, but it is not advised that they be used in the blend as a regular thing. Green tea (Gunpowder, Young Hyson, Hyson, and Imperial) is rapidly going out of consumption in the United Kingdom, but, if necessary, "Pinguet" Gunpowder may be bought in boxes (25 to 35 lb.), from 8d to 1s 6d per lb., or "Moyune" Gunpowder (preferable in liquor), in half-chests (about 60 lb.), from 8d to 2s 6d or more per lb. Assam and Ceylon teas are used almost to the entire exclusion of China tea in Ireland, and many Assams so used are broken-leaf teas, drawing dark rich liquors. It will be unnecessary ever to buy Java or Japan tea, though a little Oolong may be introduced if the pungent liquor is liked.

When a connection in tea is once established it is not advisable to change prices, kinds or qualities or proportions of mixing, without good reason. People who are accustomed to one kind of tea usually object to a change, even though it may really be for the better. Packages of tea when once opened should be kept exposed to the air as little as possible, as foreign flavours

and damp are readily absorbed by the leaf, and this is of special importance in the case of a chemist's shop; if possible, a small room should be set aside exclusively for blending and storing tea, which should never be loose in the shop. Where the amount of trade warrants the expenditure, a tea-mixer should be bought to ensure thorough mixing, and a mill (though not so important as a mixture will be found most useful in reducing the size of bold-leaf teas, such as Assam and Ceylon Souchongs and Pekoe Souchongs. Tea-tasting pots and cups should be used in buying, and water just boiling poured on leaf to the weight of a sixpence, six minutes being allowed for brewing. The teas should first be tasted singly; and though the chemist may have very vague ideas of tea-tasting, he will very soon detect and reject any objectionable tarry or burnt flavour, and the eye will be sufficient judge of thickness and richness of liquor. The blend may then be made up from the liquors, and tried without and with milk.

Lead packets are the best for preserving tea, though they are most expensive. The lead or foil can be bought in the shape of the packets, and only requiring filing, closing up at one end, and labelling with a striking distinctive label. Paper packets can be bought in the same way, but great care must be taken that the paper is not porous and that it has no smell; and as some skill is required to turn out packets either in lead or paper in a presentable form unless the lead or paper is already supplied in packet form, it will be best, at first at any rate, to incur the small extra cost of so purchasing it. Paper may be used for the 1s 4d and 1s 8d blends, lead for the two higher-priced ones. The usual adjuncts of bills, showcards, transparencies, &c. will be needed to bring the merits of the respective blends before the public.

It may, perhaps, in conclusion, be worth while to emphasise the fact that it will be absolutely necessary to sell teas at prices, below 2s per lb. if success is to be attained, except, perhaps, in cases where a chemist has a very select clientele indeed. It will probably be found that tea will be invested with an additional charm if it can be recommended by the faculty as specially digestible, and this may be attained by rigidly rejecting, in buying, the more astringent liquoring Assams and selecting softer and smoother liquoring teas. Analysts' certificates are sometimes made use of in this connection.—*Chemist and Druggist Diary*.

PROPOSAL TO ISSUE SEED PADDY, (AND COTTON SEED) TO BE RECOVERED WITHOUT INTEREST.

Galle, Sept. 28th, 1889.

P. A. Templer, Esq., Government Agent, Southern Province, Galle.

Sir,—Although I have not had the honor of serving under you or being known to you personally I feel that from the interest you have manifested in the progress and advancement of the province under your administration the subject of this communication will be considered of sufficient importance to need no apology for the liberty I take in introducing it to your notice. The subject of agriculture has long engaged my earnest attention, and although I have to some extent, under the encouragement and support of your predecessor, succeeded in establishing the advantages of a system of paddy cultivation by means of imported seed, cultivators could not be persuaded to patronise the scheme to any appreciable extent. The laudable efforts also made by Government through the Agricultural School to introduce improved methods, whilst they have gone a great way to impress the native agriculturist with the advantages of modern appliances have not yet proved a perfect success, and in a majority of instances to the poverty, and not the apathy* of the native agriculturist is to be attributed I think in a very great

* They generally go together. Apathy, too frequently both the cause and the consequence of poverty. Poverty comes as the retribution of apathy, and then poverty instead of rousing to effort intensifies apathy. The cure lies largely in the exercise of a paternal despotism by Government authorities.—Ed.

measure, the abortiveness of schemes hitherto initiated for his special benefit and the public generally, I have discovered that one of the chief objections to the village agriculturist undertaking cultivation is to be found in the prohibitive levy of 50 per cent on the seed issued to him, which he is liable to make good, subject to no conditions and which in the event of unforeseen casualties has operated as a serious hardship. Taking the foregoing into consideration I have devised a scheme for affording the agriculturists greater facilities, and as any suggestion which may have for its object the development of local enterprise and the cultivation of local products generally and serve as a means by which the agriculturists could be reached and persuaded to take a more practical interest in the cultivation of local products, especially the staple article, I venture to make the following proposals which I beg to submit with the earnest hope that should they be found feasible they would receive your sanction and approval, as I regard the willing and hearty co-operation of the Mutaliyars and their headmen as a most important factor to the success of any such measure, and their sympathy and assistance will entirely depend on the degree of favour bestowed on the scheme by the Government Agent of the province. To sketch the brief outlines of the project.

1. I propose the undertaking to issue seed paddy free of interest to 120 poor proprietors in the Galle district in the proportion of 20 in each Pattu, viz. 20 within the gravets, 20 in Talpepattu, 20 in Ganga-bodapattu, 20 in Wellabodapattu, 20 Hinidumpattu, and 20 in Bentota Walallawitti Korale.

2. The supply of cotton seed on the same terms provided the people chosen for this help possess lands of their own with not less than 1½ acres available for cultivation.

3. That the above be subject to the conditions set forth in the form hereto annexed.

4. The form requiring certain information is submitted for approval to subject such alterations as may suggest themselves hereafter if the scheme be approved.

In laying this little effort of mine before you, in which I have been influenced wholly by motives of benevolence, I venture to hope that it may commend itself to you and that it will receive your encouragement and support, and in the event of your reply being favorable to the project as a tentative measure, I hope to be able to extend the basis of operation in a larger scale in the future, as I have little doubt that although the natives in his ignorance and wedded to primitive ideas prefer to sow the same description of seed always, he can in time through the help of the headmen be persuaded to choose a change of seed from other districts, when it can be supplied to him on such advantageous terms as my scheme offers. I have seen some excellent samples of paddy exhibited at the last Matara show, and there are a variety of superior kinds in Batticaloa and other places which might be introduced with considerable advantage into the Galle district for sowing.—I remain, sir,

(Signed) W. JANSZ.

The particulars of information indicated by Mr Jansz include pattu, division, or district:—

1 Pattu—2 Division or district—3 Village—4 Consecutive No. of proprietors—5 Names—6 No. in each family—7 Names of fields—8 Ascertained extent; Amunams, Pella's Kurnies—9 a. r. p.—10 Probable distance of the field from the nearest cartroad.—Information by the Proprietors:—11 Description and quality of seed usually sown—12 Season of sowing and reaping.—13 Will you prefer to have a change of seed, which is better or the same which you saw?—14 Do you promise to make no other use, but for sowing only, the seed which is intended to be sent to you?—15 Do you promise to return the seed immediately after the harvest?—16 Have your garden land near your fields? if so state probable extent.—17 Will you like to try cotton on this land if supplied with seed and instructions how to cultivate?

The information required from Headmen is as follows:—

Are the people to whom the seed is intended to be lent free of interest, the bona fide proprietors of the land, and are they the worst off in your division?

Can you rely on their promise to return the seed immediately after the harvest?

Will you kindly undertake to make the recovery and hold yourself responsible for the same?

The reasonableness of the preceding question must be apparent to you, and you ought cheerfully to answer it in the affirmative, for in so answering you will be aiding the introduction of a beneficial object to the poor cultivators of your village. What do you say? Yes, or No?

The information to be supplied by Mutaliyars:—

Do you know of any valid objection to the distribution of seed, free of interest to cultivators in your Pattu?

Are the people chosen by the headmen for distribution of seed, and included in this list, the best deserving of such aid?

How would you recommend the recovery of seed given on loan? Is it in kind, or its equivalent in value? What would be more acceptable to the cultivators?

Have you any suggestions to offer or observations to make, if so, please state, they will be very acceptable and much appreciated.

[Mr. Templer has not had time yet to consider Mr. Jansz's suggestions. It occurs to us, that, in supplying seed free of interest, thin sowing should be insisted on.—Ed.]

COFFEE; LIBERIAN AND ARABIAN; COCOA CARDAMOM; VANILLA; CULTIVATION IN THE CIVIL PLANTATION, MERGUI.

Three years' reports of the Deputy Conservator in charge of the South Tenasserim division on this plantation have reached us together. In this there is a certain advantage, for we are enabled to note with ease the course of operations during more than the ordinary term of twelve months. The first item in the reports deals with Liberian Coffee. In 1886-87, we are told, some 1,340 Liberian coffee trees seemed vigorous and had a healthy look. As an experiment, the picking of the coffee cherry was put up to auction, and was brought, we are told, by a native of India for R45. It was hoped that if the purchaser made a good thing of the business it might induce Chinamen and others to go in for the cultivation of coffee. Seedlings had been offered to people near Mergui, but all had been refused. It is believed that the purchaser obtained 72 baskets of cherry from the trees, one basket yielding about two viss of clean coffee. This coffee was saleable at the Mergui bazaar at R1-6-0 to R1-8-0 a viss, but it was not known what the man's expenses had been in picking and cleaning the coffee. During the year 1,180 plants were given away, and a good stock of seedlings remained on hand at its close. The coffee continued in a healthy and vigorous condition during 1887-88, the number of trees and seedlings at the close being 2,617. The crop was collected and cleared in the garden, and resulted in a yield of 109 viss of bean coffee. The work of picking and cleaning entailed no extra expense, and as the Forest Ranger said that he could easily sell the coffee in Mergui at R2-4 a viss retail, it was decided to try the plan. No buyer came forward, however, and no coffee was sold before the close of the year. Twenty viss were sold at Tavoy by the Sub-Assistant Conservator, realising R2-4 a viss, but the money was not collected till after the close of the year. It was eventually decided to sell the balance by auction at Mergui. In the following year's report we find it stated that the whole crop of 1887-88 (? 1887-88), which is given as 113 viss, was sold for R196-14. In 1888-89 the crop was only 66 viss, and it was sold for R99 at a uniform rate of R1-8. per viss. Great difficulty was experienced in introducing the coffee for sale, but this is partly attributed to a belief that the lot bought by "a Burman" (he was "a native of India" in the original report) was badly cured, as some people even went the length of saying that the plantation coffee was unfit for consumption. However, the crop of 1887-88 was gradually cleared off, "the buyers were all pleased with the coffee; and when the 1888-89 crop came forward it found such a ready sale that the supply was not sufficient for the local demand." We are informed that the plantation coffee has now made a name for itself locally for flavour and general excellence, and is much preferred to the coffee sold in the bazaars! No explanation can be given, however, of the falling off in the quantity of crop.

As regards Arabian coffee, we learn that in 1886-87 some 175 of the larger trees died off. Five plants and 1,158 seedlings were given away, and it is noted that "the species does not thrive: the elevation is probably too low." The following year 65 more casualties were reported, the number of plants being thus reduced to 669, and the Sub-Assistant Conservator remarked, "The plants do not thrive, looking weak and sickly." Only twenty plants were distributed in that year. By the close of 1888-89 the number of plants growing was only 485, and we read: "the cultivation of Arabian coffee in the Mergui plantation is a failure, and has been abandoned." Cocoa seems also to have fared badly. In 1886-87, four trees died, leaving a total of 14. Eleven pods were obtained from the trees and from these 212 seeds were procured and some 146 germinated. The next year 127 seedlings were transplanted from nurseries, bringing the number of plants to 141. Seventy-seven were destroyed by white-ants, leaving 64 plants, besides something like 170 new seedlings in nurseries. Ninety-seven of these were transplanted in 1888-89, bringing up the number of plants to 161, of which 101 were destroyed by white ants. The termites certainly seem to have the pick of the 'Mergui cocoa. Tea barely maintains its ground, but no details are given about the plants. Vanilla seems to have flourished. It flowered in 1887-88, and in last year's report we read "the vanillierie is in a flourishing condition, none of the plants died, and the number remained at 284. The plants all flowered, but the flowers died and fell off without coming to maturity. This is attributed to want of insects to assist in the dissemination of the pollen. The Forester reports having tried fertilizing by hand among a few flowers, but without success." To this remark is attached a note that "fertilization by hand is essential in every case. Instructions regarding the process will be obtained and sent to Mergui, as the forester evidently does not know how to see a bout it." The last item referred to is Cardamoms. In 1886-87 eighteen baskets containing 1,725 plants of the Mysore cardamom were sent through the Secretariat. When the baskets were opened only 113 plants were found alive. When these were put out in the garden they were attacked by an insect and only four small plants were left alive. Of two lots of seed subsequently received one was bad. During the next year, plots were selected and cleared in the garden and seeds were planted out, and beyond the information that the four cardamom plants on hand at the beginning of the year died, this is nearly all we learn in the 1888-89 report. "Seeds were put down in nurseries and in the selected plots, but none germinated. The seed was described as 'best selected' and seemed in good condition at the time of sowing. The forester in charge cannot ascribe any reason for this complete failure." The expenditure during the three years amounted to R2,435 11-10, and the receipts to some 4 or 5 hundred apparently though this is not quite clear.—*Madras Times*.

THE COFFEE PLANTERS of Coorg are in a dilemma as to labour for their plantations. Mysore coolies can no longer be procured in sufficient numbers, so the Planters' Association has asked the Revenue authorities for assistance in recruiting coolies in Ganjam and other districts.—*Madras Mail*, Dec. 19th.

THE PRODUCTION OF IVORY.—There are annually killed in Africa a minimum of 65,000 elephants, yielding a production of a quantity of raw ivory the selling price of which is some £850,000. This quantity is shipped to various parts of the world—to the American, the European, and the Asian markets. A large quantity is, however, kept by the native princes of Africa, who are very fond of—and, as a rule, very good judges of—ivory. The production out of Africa is only insignificant, and India, Ceylon, and Sumatra together produce only some 20,000 kilogs, per year. India is the largest consumer of ivory, and China is also a good market.—*Industries*.

GOLD AND SILVER ABSORBED IN INDIA.—In consequence of the love of jewellery and addiction to hoarding of the Hindus, India has been called "the sink of the precious metals." As an illustration let us take the conclusion of the review of the trade of India in the *London Times*:—

During the 80 years since 1859, says Mr. O'Connor, India received and retained of the precious metals 113½ millions sterling of gold and 227 millions of silver, all the gold being practically withdrawn from circulation to be hoarded or converted into ornaments. Altogether since 1834 Mr. O'Connor estimates that 442 millions sterling of the two precious metals have been received and retained by India.

"ACROCARPUS FRAXINIFOLIUS,"—seeds of which are advertised by Messrs. J. P. William & Brothers, ought to be a valuable acquisition on estates up to 4,000 feet, or perhaps in this climate 5,000. Its limit on the Eastern Himalaya is 4,000 feet, and it seems to flourish down to sea-level at Chittagong. Also in Southern India, the Tinnevely name being *Mallay Kone*. Gamble describes it as a lofty deciduous tree with thin, light grey bark. Sapwood white; heartwood light red, moderately hard. Weight 39 lb. per cubic foot. The wood is used by planters in Darjiling for tea boxes and planking, in the Wynaad for building and furniture and in Coorg for shingles. It is an extremely handsome tree, growing with a fine tall cylindrical stem, handsome flowers and large bipinnate leaves, which are red when young; it reproduces easily and is fast growing. Beddome mentions a tree 27 feet in girth above the buttress, and Manson states that a windfall tree in the lower Darjiling Hills had a bole 70 feet without a branch and measured 11 feet in girth at the small end.

"LONDON PURPLE" AS AN INSECTICIDE.—A supply of London Purple, a refuse obtained in the manufacture of aniline dyes, has been recently sent from the Indian Museum, Calcutta, to Madras, for experiments on a pest, the caterpillar of a moth, *Achaea Melicerte*, known as "Janga purugu" which has been causing damage to the castor oil plant in the Madras Presidency. This moth has also been found feeding on the castor oil plant in Ceylon and Calcutta. London Purple, which can be obtained from Hemingway's London Purple Company, Limited, 60, Mark Lane, E. C., has been used largely in America for the cotton worm, potato beetle, canker worm, and other pests. It is used in the form of spray, and it has been recommended, as regards its application to the coffee leaf disease that the stems of the coffee plant should be painted with a mixture of London Purple and water applied pretty thickly like a white-wash, in a stronger dose than is applied to the tender leaves. Directions as to the mode of applying the insecticide are contained in No. 2 of notes on Economic Entomology by Mr. E. C. Cotes, from which the following is an extract:—(a): Forty gallons of water $\frac{1}{4}$ to $\frac{3}{4}$ of a pound of London Purple, three quartz of flour, the solid ingredients intimately mixed with the water by washing them through a strainer, sprayed upon the trees by means of a force pump and San Jose nozzle, were found to effectively destroy web-worm. The effect of the poison is sometimes not observable until after three or four days; care must, therefore, be taken not to overdo the spraying. . . . To drive the liquid through the nozzle some kind of force-pump is required, and a great number have, at different times, been experimented with some of them being of a most complicated nature. It is, perhaps not of any great consequence which particular form is adopted for use in India; but the aquapult force pump, which has been arranged to be worked entirely by one man, who also distributes the spray, seems to be about the best suited for general use in a country, where economy in labour is generally not so great an object as economy in the cost of apparatus.—*Madras Mail*.

PLANTING IN QUEENSLAND.

(From Annual Report of the Queensland Department of Agriculture for the year ending 30th May 1889.)

FRUIT, COTTON, &c.

DROUGHT.—It is generally admitted that no such drought as that we have passed through has ever before been experienced in this colony, so wide and far-reaching has it been in the disastrous results which have arisen from it; the agricultural, pastoral, and commercial industries having all suffered.

Numerous instances of the effects of the drought have come under the notice of this Department; in some cases, farmers who have purposed bringing a larger area under cultivation have been prevented by the hard and baked condition of the land from breaking up the soil, in others, the land has been ploughed and prepared, the seed has been sown but failed to germinate, and again the seed has germinated, the blade showing itself above the ground only to perish. Pastoralists have suffered immense losses in sheep and cattle, while commercial life, which to a great extent depends upon both agriculturists and pastoralists for its existence, has been paralyzed. The drought has not, however, passed away without, I believe, teaching a valuable lesson to those who live directly from the soil. The rainfall throughout the colony is quite sufficient for all our requirements, if proper steps towards conservation were taken. In anything like a favourable season, plant life is so vigorous that large supplies of fodder can be secured in the form of hay and ensilage, and many, who never before thought of saving hay, have made up their minds to be more provident in future, and since the breaking up of the drought a number of farmers are making ensilage, some by the stack system, others by the old silo process. In addition it has been proved that there are large underground supplies of water, which only require to be tapped to provide that element so essential to all conditions of life, pure water. In many places dams and tanks are being constructed and boring and well-sinking are being carried on.

BENICASA CERIFERA.—With the fodder plants a small quantity of this edible gourd was ordered, and the result has fully justified expectations, notwithstanding the dry season; several farmers to whom seeds were given have been most successful in cultivation of this plant, which is new to this colony, and which I believe will prove to be most valuable, both as a vegetable and as a fruit for cooking and preserving.

CHORO-GI (*Stachys tuberifera*), referred to in my last report, was supplied by Messrs. Cocking and Co., of Yokohama, Japan, and has been distributed throughout the colony, a list of the recipients of which is attached.

This tuber is looked upon as a great culinary delicacy by the Japanese, and I am of opinion that it will grow well in this climate. The tubers arrived in good condition, are now making vigorous growth, and will soon give returns.

MELON.—Kolb's Gem, received from the Department of Agriculture, Georgia, U.S.A., has proved a great success, nearly all who have grown them speaking in high terms both as to yield and flavour. One specimen, weighing 51 lb., grown by Mr. D. Jones, of Redbank Plains, near Ipswich, was shown by this Department at the Warwick and Stanthorpe shows. This is, doubtless, a valuable acquisition to our melon tribe.

GIANT HONDURAS SORGHUM.—The seed of which was supplied by Mr. J. Henderson, of Tambourine, has proved to be very valuable as a fodder plant both for cattle and horses. The returns to hand show that it has been a great success, thriving vigorously even during the dry season.

ORANGES.—Reference was made last year to an orange grown in Nepal, India. The steps taken to secure seed have been successful, a small supply having lately come to hand, and have been placed in the hands of those possessing a knowledge of orange culture.

Mr. Gibson, of Ceylon, from whom the seeds were procured, speaks very favourably of the tree, which is wild, and, so far as is known, a native of Nepal. It

is a very profuse bearer, the fruit being in size between a mandarin and jaminaram orange. The fruit is brought by the Nepalese over the frontier for sale in India, where it is sold at the rate of 200 for one rupee. The flavour of the fruit is said to be delicious.

BAHIA NAVEL ORANGE.—Two wardian cases have just reached this Department, each containing one dozen of healthy young Bahia navel orange trees, obtained from California through the Department of Agriculture, Washington. These oranges have a great reputation in America, one report stating that if the American Department of Agriculture had done nothing else for the States than to introduce this orange, it had repaid the expense incurred in maintaining it. Care has been taken in distributing them to place them with such persons as are known to be well qualified to propagate, so that in a short time this fruit will have a fair trial in the colony. The contents of one wardian case have been distributed in the southern part of the colony, and the contents of the other have been forwarded to the northern part.

The Bahia navel orange is not to be confounded with the navel orange already grown in these colonies. The Californians have tried the navel orange grown here, but have not found it to be a success everywhere it is tried, but if successful in one or two places, it will, doubtless, soon repay the cost and trouble of introduction. As its name indicates, this orange originally came from Bahia in Brazil, whence it was introduced into America in 1870.

OLIVES.—The attempt made by this Department to get our agriculturists to take an interest in olive growing was made at a most unfortunate time, the dry season setting in just as the truncheons were distributed proved anything but conducive to success; nevertheless, in some cases the truncheons have started a growth and the present favourable season will, doubtless, enable them to obtain a fair hold upon the soil, and possibly this Department will be in a position to report more favourably next year.

RIPARIA.—A small parcel of the seeds of this vine was kindly placed at the disposal of this Department by J. Mackenzie Shaw, Esq., and have been placed in the hands of some of our viticulturists. This is the Riverbank grape of the Americans, is a native of that country, and is largely used both in Europe and America as a resistant stock on which to graft European varieties. In view of the probability of a visit from the dreaded phylloxera, it is well that our viticulturists should be armed with resistant stocks. Some of the seeds have germinated, and will in due course provide plants for future operations.

COTTON.—There being evidence of a revival of the cotton industry in the West Moreton District, steps have been taken to secure a supply of cotton seed from the Department of Agriculture, Georgia, U.S.A.

BAMBOOS.—Eleven different varieties of Bamboos, entirely new to this colony, were secured by Sir Thomas Mollwraith during his recent visit to Japan and have been placed at the disposal of this Department. They will be placed in the various Botanic Gardens of the colony for propagation.

INSTRUCTOR IN AGRICULTURE.—The Department of Agriculture, Washington, have not yet recommended a gentleman for the position of Instructor in Agriculture in this colony, the latest information on the subject, extracted from a newspaper cutting, being to the effect that a large number of applications had been lodged in Washington, and that the Commissioner would shortly make a selection. It is to be hoped that this position will shortly be filled, and by a gentleman possessing a knowledge of agricultural chemistry, and thus the successful working of this Department would be promoted in a marked degree.

Colonial Botanist's Office,

Queensland Museum, 25th March, 1889.

SIR,—I have the honour to forward the following report of work done during the past year, state of Botanical Library and Queensland Herbarium, &c., in my charge. As one of the Commissioners appointed to collect and prepare exhibits for the Centennial International Exhibition held in Melbourne, I devoted

much of my time to the work, being anxious that Queensland should not, if I could help it, come behind any of the other colonies in her exhibits derived from the indigenous vegetation. The shortness of time—only six months—left to the Commissioners for the work of gathering together an illustrative collection of the colony's products, however, prevented that full display of our natural resources which might have been obtained had more time been allowed for the work. However, as it was, the colony had no need to be ashamed of what she sent, while she has every reason to complain at the smallness of space allowed for the display of the articles sent. Our exhibit of indigenous woods, which comprised 537 kinds, is probably the most varied and valuable ever seen from a single British colony, and, I am glad to say, was duly appreciated by visitors to the exhibition. It will be understood that this large number of woods could not have been collected and prepared in the short time allowed for collecting the exhibits; but when preparing the wood exhibit for the Colonial and Indian Exhibition, I had a duplicate lot prepared, thus giving a start for the present exhibit, of 462 kinds. I have again had each fresh kind prepared in duplicate, so that a set of these fresh kinds may be forwarded to Europe to augment the collection there which I believe has been handed over to the Imperial Institute.

It may not be generally known that in Queensland we have about 900 different kinds of woods, or, say, an equal number to that of India, and far in excess of any other country. Seeing this I would urge upon the Government the desirability of devoting some small vote towards the expense of carrying on the work of collecting and preparing as full a collection as possible of our indigenous woods upon the same plan as already begun; and also that experiments may be carried out to prove their adaptability for various kinds of work. As with woods, so with grasses, Queensland stands unrivalled in point of number and nutritious kinds. Although the time was short for the work, I prepared a mounted exhibit containing 162 kinds, a number never before equalled at an Australian exhibition. Of both the woods and, grasses I prepared full descriptive catalogues which, after fulfilling the requirements of the exhibition will be useful works of reference on the subjects.

The excellent collection of economic plants which I collected here, and afterwards arranged in a conservatory at the Centennial Exhibition, proved one of the most instructive and attractive of our exhibits. The plants, however, suffered much at first from the cold, as the conservatory could not be supplied with artificial heat. The pamphlet also which I prepared, giving a sketch of all the plants of an economic character at present in the colony, has been eagerly sought after, both here and at the Exhibition, as it forms a ready work of reference on the subject.

PHYLLACHORA ASPIDEA, Berk. and Br.—This fungus, which was first found on the foliage of *Ficus repens*, at Ceylon, was received from Mr. J. Keys on the leaves of one of our native figs from Bundaberg.

MACROSPORIUM PEPONICOLUM, Rabh.—Some Pawpaw fruit received from Mackay were so badly affected with this fungus as to be useless forwarding to the Centennial Exhibition, for which they were intended. In several parts of Europe this fungus attacks the fruits of the pumpkin and melon family, hence Rabenhorst's specific name for the plant.

LANTANA CAMARA, Linn. Black Currant Shrub.—This is perhaps the most troublesome of all our naturalised plants, as it occupies the land to the expulsion of all else. Mr. W. S. Campbell, speaking of this plant, Report on the Richmond River District, says: "On each side of the road from Wyralla to Lismore, and also for some miles around Lismore, hundreds of acres of land that had once been cleared of timber have become utterly useless from the spread of this shrub."

PHYTOLACCA OCTANDRA, Linn.—The Red Ink-plant or Poke-weed. This plant, which has only been introduced now but a few years, bids fair to cause much trouble both to the agriculturists and pastoralists: some farms seem to be quite in possession of the pest; this is especially the case at the Rosewood, But

from Mr. W. S. Campbell's account, it must be even worse on the Richmond River, for he says, "there it grows to such a height as to in places hide the settlers' houses."

RICINUS COMMUNIS, Linn.—The Castor Oil Shrub.—Doubtless a most useful plant, but too fond of occupying the rich lands bordering on rivers.

DIRECT INFLUENCE OF POLLEN ON THE ORANGE.

In spite of what some botanists set forth as Nature's unvarying law, the question of the immediate and direct influence of pollen on fruit should, in the matter of the Orange and Lemon, and all Citrus fruits, be considered as one which has been settled.

For weeks each season I have been carefully examining the exterior and interior of Oranges growing on Maltese Blood trees, and on the Imperial Blood of the St. Michael family, which have a navel mark not common to either family. I have singled out these two families of the Blood Orange with the navel mark because I consider the three Oranges as the best of all Oranges, and have made careful experiments for years, hoping and expecting to combine in one Orange the superior points of the Blood and the Navel.

These Blood Oranges having the navel mark are completely changed in outline, in their exterior and all through, by the effect of the pollen of the Navel trees. From being naturally oblong, they become somewhat flattened, the flavour is changed, and the cellular form of the pulp is changed.

Of twenty Oranges having a navel mark recently cut from a Maltese Blood tree, standing beside a Washington Navel tree, only two of the Oranges had a single seed, eighteen were seedless, while nineteen in twenty of the Bloods which were not marked by the navel had one or two seeds. Not always does the pollen of the Navel show its effect in the lengthened axis. Sometimes you find an Orange shaped like the Navel except the umbilical mark is wanting on the outside. Inside there is no axilar centre; the inner Orange has spread all through the fruit. There are two sorts of pulp, two sorts of fruit-cells, and two separate and distinct flavours.

A few times I have seen an Orange cut from a Majorica tree, one side almost solidly coloured, like an Imperial Blood, pulp dark as wine; the other side not a trace of rubricate, the divisions of fruit-cells as distinct and clear as though they had been fenced off by an impassable dividing line. One side the decided piquant flavour, sub-acid, that a thirsty man gratefully remembers on a hot day; the other, the fruity flavour of a Strawberry or Black-cap Raspberry, with juice quite as dark as that of the latter berry. Such an Orange I cut at Ocala during the exhibition last winter, and observing visitors noted the difference in flavour as well as strong contrasts in colour in the two sides of the same Orange.

Some time later I cut a Prata Orange, such as L. W. Sherman, of Boston, sells for "whites," because the rind is a pale lemon colour. I noticed before I cut it, longitudinal, single rows of rubricate oil cells, running from flower to stem as straight as the lines of longitude on a school globe. The opposite cheek of the Orange had splashes of them, giving a beautiful contrast to the pale lemon shade. I was not surprised to find in the pulp, usually as pale and white as a Villa Franca Lemon, rubricate tints.

I then went to the row of trees on the opposite side of the Blood Oranges, and soon found on one of the outside branches of the Ribbed Du Roi, an Orange well marked as a Du Roi, save the blossom end, which was a well-defined Blood. I cut and found a more deeply-coloured Orange than the average Bloods, with not a seed, although the Du Rois are not wanting in seeds.

Among the ornamental dwarf Orange trees at Beliard President Berckmans, during a visit last winter, called attention to one found with rind not unlike the shell of

the old Crook-neck Squash when ripe, the exact counterpart of which he had seen on a tree in a distant part of the grounds. The distant tree originally came from Japan, and has not been bearing more than three years. I know such Oranges were never seen there on the tree on which he saw it, till this one strange tree began to bloom and bear fruit. Now tracks of this ribbed and warty fellow are again and again seen on the other trees.

In March last, I cut a cluster of five Oranges from the tree sent me by Wm. Saunders, Superintendent of the Grounds of the Agricultural Department at Washington, labelled Bahia. The cluster looked precisely like similar clusters growing on an adjoining St. Michael tree. Cutting them all, I could see no difference in seed or flavour from the St. Michaels; the same sharp acid, the thicker, rougher, and tougher rind than that of the Navels—not a thing to remind one that the sap of a Navel tree nourished those five St. Michael Oranges.

Some years since, I procured from A. W. Rountree, of New Orleans, the Double Imperial Orange. I budded a number of trees from the tree he sent. They bloomed fully for the first time last February and March. The past summer and autumn I found again and again Oranges on adjoining trees so exactly like the real Double Imperial, that the novice would say they were the same. This Orange (the Double Imperial) has an exterior, as E. H. Hart says, *sui generis*, and quite distinct from most Oranges. It has as much pollen (yellow, too) as any Orange bloom I ever examined. It is one of the coming Oranges for Florida.

Meanwhile, let me say, a race of Oranges which can completely metamorphose whatever other variety its pollen touches must be most prepotent indeed. Out of the two strains, the Navel and the Imperial Blood, will come the future Orange, which the intelligent lovers of the queen of fruits will say are the best. Their price will depend on the conscience of the seller. Note that Pelermo Imperial Bloods on March 1, sold in Boston at 4-35 dols. a box, when average Palermos sold at 1-50 dols, and less. *Lyman Phelps.*

(The phenomenon of the direct influence of foreign pollen upon the fruit of various plants has long interested naturalists. It is a matter of much practical importance, too, to horticulturists, if certain fruits, especially those belonging to the Squash and Melon family, change and deteriorate, as some assert, by the influence of the pollen from other plants of the same family acting upon the ovaries from which these fruits develop. Persons interested in the subject will find a summary of what is known about it in a paper by M. Maximowicz, published in the *Journal of the Royal Horticultural Society*, new ser. iii., p. 161. See also Darwin's *Animals and Plants under Domestication* (English ed.), i., 39; Asa Gray, in *American Journal of Sciences and Arts*, 2 ser. xxiv., 442, and Darlington's *Fl. Cestrica*, 2 ed., p. 555.—Ed. *From Garden and Forest.*)

TEA IN UVA.—Of my old district I shall not say very much, for I had not time to see much more than my own property. I think proprietors of Haputale estates may look forward to having some of the best and most profitable tea in the Central Province. If tea is added to deep rich soil and a forcing climate, it will find a congenial home on the Haputale ranges. It is growing best at the higher elevations, but I am sanguine that it will also do well at 2,000 feet, although the difficulty of establishing it so low down is greater. Much will depend down there, I suspect, on libera expenditure in planting operations. As to coffee, it may interest absent proprietors to hear that, on the whole, I found my good coffee looking far better than when I left Ceylon, two-and-a-half years ago. I found some of my upper fields looking as well as ever they did. Many fields of coffee which, when I left, were blasted by green bugs, are now clean, vigorous and full of crop.—*Cor., Local "Times."*

THE FINEST COCONUT PLANTATION in the island of its size is described to us by a good and impartial authority, as probably that recently created in the Mirigama district by Mr. W. H. Wright. It now covers 250 acres planted, from this year's clearing up to 3 years old and in 3 or 4 years more, it is expected the first fields will be coming into bearing. Meantime the plantation is a perfect picture of careful cultivation while the mansion, garden and grounds afford a capital illustration of how a country gentleman with taste and means, and we may say special experience and industry, can make life pleasant and profitable for himself and his family in the jungle.

JOHORE NOTES.—On all sides I hear good accounts of the coffee crop. Yesterday a planter described his bushes to me as "red with ripe berries." This is capital!—but only, oh only, don't! We hear of a forward move on the part of the proposed Straits Planters' Association. Since their circular—(how many months ago?)—we've heard nothing; and, deny it who can, our labour is not as satisfactory as your extract from the *L. and O Express*, in your issue of 7th inst. would make it out to be. A little less of the *couleur de rose*, Mr. Editor, please! Undoubtedly, the S. P. A. is the body of all others to tackle this question.—*Cor. Singapore Free Press, Dec. 11th.*

THE SIZE AND WEIGHT, QUITE EXCEPTIONAL OF THE FAMOUS ELEPHANT "JUMBO," are thus given in a notice of Barnum's show:—

The stuffed figure and the skeleton of Jumbo, who, it will be remembered, was killed by a railway train soon after his arrival in America, are the first objects that catch the eye of the visitor to Olympia. They are very typical of American enterprise. Many persons, perhaps, would have had the idea of preserving the bones of the famous elephant, but it needed a Barnum to perceive that, to borrow the language of the profession, there was money also in his hide. In Mr. Barnum's hands Jumbo dead has in fact become an even more profitable speculation than Jumbo alive. It is stated that his skin when removed weighed over three-quarters of a ton and varied from half an inch to an inch and a half in thickness. Standing in a life-like attitude, the stuffed Jumbo presents a very imposing spectacle. The skeleton is no less so. When alive Jumbo stood 12ft. high (to the shoulder), measured 18ft. round the middle and 14ft. in length, and weighed seven tons. His skeleton is declared to be the largest of any terrestrial mammal of the present geological era.

JAMAICA, Nov. 18th.—Writing to renew his subscription for the *Tropical Agriculturist* for the present year, Mr. W. W. Wynne of Brokenhurst, Mandeville, Jamaica, says:—

In this part of our island we have had fine "seasons," and my crop for 1889-90 is an average one, and if the present nice pouring rains continue there is every prospect of a bumper crop for 1890-91, *i. e.* of course "The Planter's Year" (next), but one never knows what the crop will be till it is in the pulper loft. Last July the heavy rains and high winds cost me a good fifteen times of 850 lbs.: it cut off all the young berries towards the ends of the primaries. I have planted within the last two years and-a-half 230 acres, on the system that prevails in these parts, viz. by giving out the virgin land to Negroes for three years rent free, my undertaking to cut down the trees, clean up and get ready for lining and pegging. After this is done by me, they plant their provisions, yams, plantains and bananas, between the rows. I plant my suckers when it suits me, generally before the October rains, so that, as I give out the land early in the spring, the bananas etc. afford a good shade for them. I hear from Mr. Sabonadiere that in his district the rains have been too heavy and the crops are very small. Thanking you for the vast fund of valuable information your excellent paper affords.—Believe me, &c., yours very truly,

WALTER W. WYNNE.

Correspondence.

To the Editor.

COFFEE AND TEA PESTS &c.: THE BEST OF EMULSIONS.

Queensland, Nov. 12th.

DEAR MR. EDITOR,—The following will suit your island to perfection. Fill a 5 gallon drum with water, adding $\frac{3}{4}$ bar of cut up common soap; dissolve; then add 1 full pint each separately tar and grease (bullock fat)—a residue settles to the bottom, which carefully collected and rubbed between two pieces of board in hot water dissolves it; mix this and the first 5 gallons together with hot water sufficient to make a total 20 gallons. Your leaf disease and insect pests will now have it:—apply as hot as you can with syringe or strawsonizer, the finer the spray the better. The emulsion looks like dirty water, but it is a thorough cure and does not hurt young tender leaves, neither will it wash off readily through rains.—Ever yours,

A WANDERER.

THE KOLA NUT; GOOD DEMAND; WHO WILL SUPPLY IT?—LIBERIAN COFFEE.

London, Nov. 29th.

SIR,—The present is to inform you that there has been a considerable movement in the kola.* The consumers in all directions are finding that it is an agreeable food and beverage, doctors are also finding that it is extremely valuable as a sustaining remedy in certain cases where they have to give powerful medicines, travellers have proved its value when exposed on long journeys, and delicate women and children find it far more nourishing than cocoa (*Theobroma cacao*); even in the hunting field gentlemen take a small piece 1 inch by $\frac{3}{4}$ inch by $\frac{1}{2}$ inch thick which sustains them for a whole day without having recourse to any lunch.

This is one side of the question, the other is that up to the present time the best supplies of kola, in fact, the only nuts that could be relied upon to come over in good order, have been the West Indian. But later shipments that have arrived from the West Indies have not come in good order, they have been shipped before they were properly dried, hence when they were cut with a knife in the centre they were quite soft, thus causing the nut very soon to go mouldy and wormy.

Immense quantities come from Africa, but generally speaking these are shrivelled up, dried, rotten, evidently picked from the ground, and altogether anything but an inviting commercial article. Again, the African nut we observed was of two natures: one, which divided equally into two sections, broke with an astringent flavour, the other had a fracture exactly like glass, when dry sometimes pink, sometimes brown, and with a sweet taste. Lately we have received from the island of St. Thomé a shipment of sprouted seed which we discovered had 4 and 5 divisions in place of the ordinary variety that we had been accustomed to with two divisions; they further had a thin shell on them, they were similar to those breaking bright. The first thing I did was to send these off to Prof. Heckel of Marseilles, and he advised me not to issue them as they were an unknown variety which he thought ought not to enter into commerce. We explained to him that these nuts produced the dry kolas which broke with the bright fracture, and we planted some at Sydenham, but it is too soon yet to pass any remarks on the foliage.

Hearing that Prof. Oliver of Kew had written on the *Sterculia Acuminata* and its varieties we sent him

* An increased use of Kola nuts, we presume.—Ed.

specimens in all the different forms together with the nuts that divided into two, but he has been unable to throw any light upon the subject.

Seeing that so many planters in Ceylon and Southern India have determined to go in for planting the kolas, I secured a good supply of the seed of the variety breaking with equal divisions, and a considerable portion of this has gone forward by the steamers lately leaving London. There is no doubt that some of the planters will be getting seed sent to them, and it is important that these facts should be placed clearly on record in your paper, which reaches every planter in the island; and if you will let me I should be very glad as soon as we decide the qualities of differences of this kola before referred to with the 4 and 5 divisions to lay the particulars before you.

One word in conclusion in regard to Liberian coffee. You will remark by the papers that this has now run up to 100s and is in considerable demand. The Dutch have kept to the front, and up to the present time have made it a rule throughout the Colonies to invariably send home for fresh seed, they never plant the coffee seed from their own trees with the view of establishing plantations.—Yours truly,

THO. CHRISTY, F.L.S.

[We shall be glad to hear further.—Ed.]

CEYLON TOBACCO FOR EGYPT.

Alexandria, Egypt, Dec. 9th.

DEAR SIR,—I beg to acknowledge the receipt of a copy of the *Ceylon Observer* of the 12th ultimo, and at the same time tender you my best thanks for having kindly given publicity to my letter respecting tobacco. In addition to the low priced tobacco there is also a market here for chewing tobacco ranging from 3d to 5d per lb., and I shall be very glad to hear from any of your planters on the latter article. The native taste in chewing tobacco runs into a very strong kind, and the leaves should be laid out flat and tied in bundles and be of a dark quality. I think a very large business might ultimately be done between Egypt and Ceylon in the tobacco trade,—I remain, dear sir, yours sincerely,

J. M. ROBERTS.

PLANTING IN PEERMAAD, TRAVANCORE:—A REPLY.

Penshurst Estate, Peermaad, Travancore, Dec. 11th.

DEAR SIR,—In your November issue of the *Tropical Agriculturist* there is an extract from the *Pioneer* on the present condition of Peermaad so strangely at variance with facts that I trust you will allow me space for a reply. If the writer had wished to convey to his readers a fair impression of the district, he should have visited the whole of it, instead of confining his attention to one small portion where the coffee is unfortunately not what it used to be in days of yore. I cannot find that he extended his visit beyond a few semi-abandoned estates, on which he expatiates as though they constituted the whole district. One would almost be led to believe, judging from his other letters to the *Pioneer*, that he had some personal interest in another district of Travancore, which he praises as loudly as he decries this. If he had torn himself away from "the valley exposed to the full fury of the S.W. Monsoon," eastward to the Perriar, southward to Arnakul and the Mount, and northward to Ferrintorra, he would have seen coffee trees loaded with crop in spite of leaf disease, tea both in old and new land flushing heavily, and cinchona in a thoroughly healthy condition. He might then have altered his opinion, and thought that Peermaad had a future before it and does not complain of its present.

He says that the elevation is too low for the growth of flavoured tea. Considering that the elevation is from 3,500 to 4,000 feet, this statement to any practical man carries its refutation on its face. Will you kindly, Mr. Editor, give me your opinion on three samples of Peermaad tea I am sending you by this post?

As to cinchona, we have little else but succirubra; but as it flourishes and pays (my last sales averaged over 3d net) we do not grumble.

Our friend indulges in a wild flight of imagination about the number of planters here eight years ago and now. There were never 40, and there are now more than six *bachelors*, not to mention all the married men, and since eight years ago Peermaad has become very much married. This does not look exactly like ruin.

If this *Pioneer* correspondent should ever visit Ceylon, I would recommend you to insist on his addressing his impressions to the *Observer* instead of to some far-away paper. Before it came to hand he might be beyond the reach of vengeance.—I am, dear sir, yours faithfully, F. M. PARKER.

[Mr. Parker sends us three samples of well-made nice-looking tea which we must try; but he ought to get the report and valuations of an expert.—Ed.]

"PLANTERS' ENERGY" AND RAGS.

Kelani Valley, Dec. 13th.

DEAR SIR,—I was delighted last night to read in the *Observer* that article from the *Daily News*. More power to the editor's elbow. We drank his health with all due decorum, and we all felt inclined to embrace that man. I can't imagine where he got hold of the cedars of Ceylon. He must have had his head jammed into a Ceylon Japan cedar tea box on some auspicious occasion.

I was equally interested, too, in reading your leading article lately on rags as a manure for our tea, and I have no doubt that such a fertilizer would be just the ticket, as there's no denying the virtue of certain old rags even those of Ceylon, and it is certain that something must be done in this direction if our present yield of tea is to continue.

There are, as you know full well, however, rags and rags, the good old 12½-center of 1837 as also that jumped up 5-center just beginning to make itself known a bit, but of course it can never hold a candle to the yeoman services of the "old un."

I maintain that your own old rag has done more for the planting enterprise of the colony—this isn't more soft soldier mind you—than all the other rags heme and local put together. I fancy I can see you blushing, with your usual modesty, and it reminds me of the story of the very plain young American proposing to a very pretty young lady. He said "Bessy, do you love me?" No reply. "Bessy, do you love me?" No reply. "If you love me, Bessy dear, and don't like to say so, just squeeze my hand."

What I'm worrying about now, however, is, that if H. K. R.'s rag manure succeeds, rags will go up in price, and you, dear *Observer*, will feel it, for as paper is made from rags, you will have to pay more for your raw material. Let us therefore look before we leap a bit and not embark too precipitately in any new enterprise at this time, particularly one that would be likely to affect the press of Ceylon and the price of the printer's paper.—Yours faithfully, L.

P.S.—Of course if rags increase the yield of our tea, and you have to pay in consequence more for your printing paper, we can well afford to pay you a little more for your periodicals.

FIBRES AND FIBRE PLANTS.

Dolosbage, Dec. 16th.

SIR,—Referring to your article on the production of fibres in Ceylon: as one whose business was formerly with fibres and ropemaking, I would recommend the introduction of Manilla hemp, should it be found that the aloe and common plantain,

now growing in the island, can be satisfactorily treated.

Aloe and sisal only came into the English market for ropemaking when Manilla rose to such a high figure some 7 or 8 years ago.

Mauritius hemp was used previously for fancy white cordage, being a very clean fibre, but more expensive than and inferior to Manilla. I think Manilla will always hold the position of the best fibre for ropes, and that an increase in its production would cause by the reduction of its price, a falling-off in inferior hems.

Is there not a planter who has seen the hemp grown and treated in Manilla who can help to solve the question whether Ceylon is able to cut out Manilla in hemp as China in tea? If the hemp be produced, I think, it would be found that by manufacturing in the island with our cheap labour and water-power Ceylon could send rope into the market at a very low figure. In conclusion I would remind you of the great strides made in steel ropes during the last few years, and point out how little hemp rope a steamer takes nowadays as compared with the tons used in the outfit of a sailing vessel some years ago.—Your truly, E. F. DAVIS.

[Any information of a practical nature is valuable. Caution is necessary in this as in other cases, but trials ought to be made. We are more hopeful of success from aloe than from Manilla hemp.—Ed.]

IS THE TEA HORNET AN ENEMY OR FRIEND?

Lethenty, Dec. 17th.

SIR,—During the last few months, from what cause I cannot say, the hornets, which were until then very numerous upon this estate, have disappeared. Since their departure I have noticed an increase of the caterpillar which devours the tea bushes, secreting themselves in rolled up leaves, and in some places there are more this season than I have noticed before. It has occurred to me that there may be some connection between these two creatures.

About eight years ago I most carefully watched the habits of the hornets, and bar an occasional onslaught among the coolies when overtly molested, all else was in their favour. I found them voracious and predatory in all their habits, nor on the other hand, when undisturbed, did they ever appear disposed to attack human beings.

I have often seen coolies plucking the bushes containing a nest without any injury resulting. I also noticed that during the north-east they did not appear to prosper so well as during the south-west monsoon.

Caterpillars, moths and the coffee-grub beetle I have observed them carrying away, and if a pound of beef were hung up in any proximity to their nest I would engage that it were all devoured or removed in an hour or two. Often I have noticed them trying to catch bees, but I do not remember witnessing the attempt proving successful. The beetles in rose blossoms were removed by these good custodians, and I have an idea that we are very much indebted to them for the good done in this and probably many other ways we know nothing of. I doubt if there is any family of insects so useful to us as the Hymenoptera in removing the insect enemies to which tea is subject.

From what I have heard recently I imagine a war has been waged against the hornets, the consequence possibly being an increase of these caterpillars. Our estates are not sufficiently wooded to induce small birds in large numbers to come amongst us. Last week I saw some honey-birds (*Cinnamomum zeylanicus* Legge) very busy where the caterpillars were the worst.

What I state and would draw to the notice of tea-planters is simply with a desire that they should hesitate before destroying what though on open enemy may be an indispensable friend in disguise. I would most earnestly draw the habits of this abused hornet to the notice of planters. It would be very satisfactory to know from others whether the presence of hornets has resulted in an absence of caterpillars and *vice versa*.

Let any aspirant for information place himself with a binocular within a reasonable distance of the nest and watch what the hornets are taking in about 9 a. m. I have found their busiest time.

W. F. L.

[This is a very interesting addition to the information we collected and published recently on the hornets following tea cultivation to higher altitudes, and we shall be glad to hear from observers of the hornets and their habits.—Ed.]

THE BLACKMAN FAN IN TEA WITHERING.

Holmwood, Agrapatana, Dec. 23rd.

DEAR SIR.—In the interesting account of the Blackman Fan Withering at Sitcoorie there seems to be some error. The width of the room is said to be 45 feet, and yet there are only 4 rows of withering shelves each 2 feet wide. This would give 37 feet of waste space above and 14 feet waste in the annex. It also says a bamboo shield is placed *below* each fan which would seem to imply the fan being on floor level with vertical shaft. Now as the opposite slit is on the floor this arrangement would only suck a current of air along the floor. Again if on the ground floor, only 100 × 45, there are sufficient driers to work off, after withering and rolling, 4,000 lb. made tea all between 7 a. m. and 5 p. m., the heat would seem sufficient to wither anything. The firing could not begin before 11 a. m., which leaves 6 hours to fire 4000 lb. made tea. The lot of the "cha bungalow sahib" who works in that factory must give him a foretaste of his future state!

R. W. W.

[We quoted the account from the *Indian Planters' Gazette*.—Ed.]

DR. ASHMORE OF CHINA ON THE "CEYLON HANDBOOK AND DIRECTORY"—AND ON THE EXTENDED USE OF QUININE IN CHINA.

DEAR SIR.—Thank you for the sheets of the "Handbook and Directory." They will assist greatly in the elucidation of the subjects of inquiry I have in hand. I have been in the habit of studying Directories and Handbooks the first thing in every place to which I have gone, but have never seen one that for fulness and variety of information comes quite up to this one which you have prepared. I have been surprised at the multitude of my questions which are answered at a glance.

A single word on the one subject of Cinchona: Any great increase of the yield of the valuable medicine derived from this tree and consequent cheapening of the product must prove an invaluable blessing to China. It is already in great demand among those who know its use. Hitherto its price has been so high that the poorer people could not purchase it; with a lowering of this price must come a greatly increased call. In our tours among the Chinese the inquiry for it is constant; we do not think of going out without a supply which we dispense only in specially needy and deserving

cases. It is used extensively not only for fevers but also for a general tonic. The Chinese have nothing whatever in their whole pharmacopoeia which can take the place of it for those specific purposes. All that is needed to have it far more extensively used is to have it known.—Yours, under obligation,

WILLIAM ASHMORE.

COOLIES FOR ASSAM.—The authority given by the Madras Government to recruit for coolies in Ganjam and Vizagapatam for the Assam tea gardens is about to be taken advantage of in more than one direction by planters and their agents.—*M. Mail*.

THE SECOND GEMMING SYNDICATE which was noticed in our London Letter a few weeks ago—its registration being recorded—is mainly the work by a relative of Mr. Davis, partner in Messrs. Gow, Wilson & Stanton, a gentleman who has had experience in connection with South African Mining Companies. The promoters are men of influence and include Messrs. Anderson Brothers of Philpot Lane, while Mr. Wm. Somerville of the wellknown Colombo Broking firm is down as Secretary. They will commence operations in our Gemming country very shortly we believe.

QUININE.—Some time ago there was a very animated discussion in your columns with reference to the bad method of administering quinine. The general opinion seemed to be in favour of heroic doses, but all were unanimous in the view that it should be administered as a stimulant. There was a good deal of writing on this subject afterwards in the European medical journals, and no doubt the arguments put forth were widely read. As the consequence we find that quinine is being largely administered to the Russian soldiers both as a prophylactic and a cure in the case of the outbreak of influenza in that country. The quinine we read is always given to the troops in Vodka, a native brandy.—*London Cor.*

MR. R. E. PINEO IN AMERICA.—Mr. Pineo has been interviewed by the *San Francisco Chronicle* and over a column is devoted to the result, the heading being "Tea from Ceylon." There is nothing of novelty to our readers, save one blunder of the reporter which makes Ceylon to give "900,000 cents of coffee now against the million in 1869—deficiency 100,000." These figures should of course be reversed: 100,000 being above our export now. Mr. Pineo left for British Columbia soon after the interview. The correspondent who sends us the paper, lives in St. Louis, and adds that ordinary black Ceylon tea costs 75 cents (of the dollar) per lb. in St. Louis—that is 3s 6d per lb. (in silver)! He goes on "I bought one lb. of Cruden (Maskeliya) tea today and paid 75 cents for it."—This is very high, the duty on tea in America being so much less than in England.

COCONUT BUTTER.—Coconut oil has been used as a substitute for cod liver oil, and now, as the following paragraph from the *American Cultivator* shews, it is replacing butter. How the peculiar odour is dispelled is not said:—

The United States consul at Mannheim, Germany, reports that German chemists have learned how to make butter from the oil of the coconut. One factory already produces 600,000 pounds daily, which is sold at fifteen cents per pound. The nuts are produced from Africa, South America and other tropical countries. Coconut butter contains seventy per cent of fat, and of the remainder, one-third is composed of albumen, which gives it a greater nutritive value than cow butter possesses. The new butter is used largely in hospitals, and is finding its way, on account of its cheapness, to the tables of the poor, especially as a substitute for oleomargarine, to which it is certainly superior as usually made.

SUBSTITUTE FOR COFFEE.

If my memory serves me correctly allusion has formerly been made by me to the subject of the following paragraph out from *the Times*. The information given by it shows that Mussaenda is not likely to be much of a rival to coffee in public favour:—

“MUSSAENDA, THE NEW SUBSTITUTE FOR COFFEE AND CHICORY.—The British Consul at Réunion, in his last report on the trade of that island, says that at one time he was besieged with letters from merchants in England asking for information respecting a shrub called “mussaenda,” the discovery of which, it had been said in some commercial journals, would deal a severe blow to the coffee and chicory trade. About two years ago a rumour was spread that the berry of this shrub could be advantageously employed as a substitute for coffee and chicory. Its true name is “gaertnera.” It grows to about 10ft. high, has very few leaves, and its branches are wide apart. The berries do not grow all along the branches as is the case with coffee, but in bunches at their extremities. At present it is only met with in the mountains where it grows in a wild state; but as it is widely disseminated over the forests, the picking of the fruit is not only an arduous, but, at the same time, an expensive process. It is just possible that, if regular plantations of the shrub were undertaken, “mussaenda” might be produced on an extensive scale, and much more cheaply than at present, but even then it is doubtful whether, by reason of its inferiority in fragrance and colour, it would ever compete with coffee to such an extent as to endanger the trade of the latter, as has been supposed in England.”—*London Cor.*

LANKA PLANTATIONS COMPANY.

COFFEE—TEA—COCOA.

It is also possible for me to send you by this mail an early copy of the Report of the Lanka Plantations Company, the compilation of which has been completed very considerably earlier than we had been led to expect it possibly could be, owing to conditions but lately mentioned to you by me. As the working of this enterprise has so much more of local bearing than has that of the P. & O. Company above but briefly referred to, I shall venture on a *resumé* of its contents despite the required encroachment on the limits of this letter. The report first deals with coffee. The quantity of this shipped home during the year was 1,656 cwt., a very slight increase on the amount received during the year previous, which was 1,601 cwt. But owing to the fact that the average price obtained per cwt. has been 92s 3d as opposed to but 73s 10d during 1887-88, it has realised upwards of £1,800 more in value, the total received being £7,728. Alas! what a falling-off as to king coffee is shown by the figures given for the year 1881-82 when the Company derived from this item of its cultivation no less than £16,704. The next production mentioned is cinchona. Of this 45,071 lb. was received, and this sold for £509. The directors express their resolution, taken consequent upon the continued depression in the market for this article, not to press its harvesting. Cocoa, which it was estimated would yield 600 cwt., only reached the figures of 423 cwt., the sales of it realising £1,499. Cardamoms also did not come up to the estimate, the Company's receipt from this product being only £133. The tea dealt with by the Company during the year was 157,567 lb., but of this 34,000 lb. was not grown on its estates. If we deduct the latter quantity, we have the production on the Company's own properties of 123,567 lb. as against 103,364 lb. in the year previous. Altogether the Company now has 1,270 acres under tea out of the total acreage of its properties of 4,097½ acres. After dealing

with the matter of production, the report proceeds to mention changes made in its management in Ceylon, and states that Mr. R. P. Harding and Mr. J. T. White retire from the directorate in the course of rotation, but offer themselves for re-election. In this report the directors have made what we believe to be a new departure, for they give in it with great detail the estimates sent home by the superintendents on their several estates for the year 1889-90, both of yield a cost of working with anticipated surplus. Nowhere in the report do we find any mention made of any proposed dividend. It has reached me at too late an hour for it to be possible for me on this occasion to tell you why this should be the case; but as, to judge from the profit and loss account, it seems apparent that the net profit of the year has been £493 7s 7d only, it is evident that the payment to preference shareholders of £414 odd in June last has left but little available for a further dividend even to them, let alone any chance for the ordinary shareholders of the Company to reap any present benefit from their investments. But it will be recollected how adverse have been the circumstances against which the Lanka Plantations Company has had to struggle ever since its formation. It has had to transform the whole of its production and we may expect to see the sum received for tea during last year, £6,360, very considerably increased year by year as the newly planted acreage comes to maturity.—*London Cor.*

TEA IN TRAVANCORE: NAGAMALLY
TEA CO., LTD.

Capital £20,000 in 4,000 Shares of £5 each, first issue of 2,000 Shares, of which 1,160 will be allotted as fully paid-up Shares on account of purchase-money, and 840 are now offered for public subscription.

Directors.—George W. Paine, Esq., (Chairman Kelani Valley Tea Association, Limited); Charles J. Scott, Esq., (of Mayfield Estate, Ceylon), Boxgrove, Guildford; Leopold F. Davies, Esq., (Messrs. Gow, Wilson & Stanton, Tea Brokers), Rood Lane, E. C. Manager in Travancore.—F. W. Bennett, Esq.,

Secretaries and Offices.—Messrs. Anderson Brothers, 16, Philpot Lane, E. C.

PROSPECTUS.

This Company has been formed to acquire the lease and develop the properties known as Culoorty and Nagamally, situated in the State of Travancore, in Southern India, approximate to Ceylon, held under a lease at a peppercorn rent per annum from the Travancore Government, of which fifty-three years or thereabouts are yet unexpired. The Vendors are now negotiating to have the lease made in perpetuity.

The property consists of

1,500 acres, of which 120 are under tea.

50 " being in full bearing.

45 " planted in 1887

15 " " 1888

10 " " 1889

and 1380 " forest, all available for tea

Included in the 1380 acres are some Nutmeg trees, Liberian Coffee, and Indigenous Tea, yielding a revenue of about £100 per annum, and which are a valuable adjunct to the property. The buildings, factory, and machinery, as described in the report, with some small additions, are sufficient for some time to come.

The price to be paid to the Vendors is £6,800, of which they take £5,800 in fully paid-up shares, and the balance of £1,000 in cash. The property is to be taken over from January 1st, 1890, the Vendors paying all expenses connected with transfer of lease and formation of the Company.

Tea estates in Travancore possess all the advantages, as to soil and climate, incidental to Ceylon, whilst labour is more plentiful and transport cheaper. The property has been very favourably reported upon by Mr. F. M. Mackwood, of Ceylon,

whose report and valuation is appended. The shipping ports are Tuticorin and Quilon, the former distant 60 miles by road and 40 miles by rail, the latter distant 46 miles by road.

Travancore Tea is becoming well known in the London market, and is much appreciated for its combined strength and flavour, and the prices realised compare favourably with those obtained for Indian and Ceylon growths. With the fine soil, evenly distributed rainfall and forcing climate, a minimum average yield of 500 lb per acre may be safely expected. The yield last year was over 600 lb. per acre from the 50 acres of tea in full bearing. The plentiful supply of labour and cheap transport afford great facilities for placing the Tea on the London market at a very low cost. Taking the yield at 500 lb. per acre, and the cost at 7d. per lb. laid down in London, which is high for Teas from this district, there will be a large sum available for dividend on an average selling price of 10d. per lb.

It is proposed to bring gradually under cultivation 1,200 acres of the 1,380 acres of Forest land, the balance being reserved for fuel and other estate purposes.

No promotion money has been, or will be paid to any person.

REPORT ON NAGAMALLY AND CULDOORTY ESTATES.

Visited in the middle of January, 1889.

Situated in Central Travancore, and held under Government title for a long term of years.

Area.—1,500 acres, of which 120 are under tea cultivation, the balance, 1,380 being heavy forest. The lay of land throughout this area is gently undulating, the greatest variation not exceeding 600 feet.

Communications.—A good cart road of about 3 miles in length connects the property with the Govt. Road to Quilon, on the west coast, distant 40 miles, and with Tinnevely on the South Indian Railway, 60 miles distant. Transport either way being cheap.

Rainfall, Elevation, &c.—The latter is a mean average of 1,000 to 1,100 feet above sea level. Climate is most suitable for tea, the rainfall being about 120 inches annually, well distributed through the ten months—March-December. January and February are generally dry, in my opinion a great advantage as affording an annual period of rest to the tea bushes.

Soil from appearance is good, consisting of light loam, with an outcrop of ironstone throughout.

Cultivated area consists of—

50 acres tea, 7 years old, previously planted with coffee.
46 " do 2 do.
15 " do 1 do.
10 " new clearing, supported with adequate nurseries.

The tea is of fair jāt in the old field; the latter plantings being of superior kind, and the two-year-old tea is, for age, the finest grown and developed tea I have ever seen; the clearings have been well planted and the older ones supplied, there being at present very few vacancies. All the clearings have been roaded and drained, but a few more drains could be put in the older tea with advantage.

The old tea has given the handsome yield of over 600 lb. per acre last season, without showing any signs of exhaustion; the two-year-old tea will give about 300 lb. per acre this coming season, and in another year will be equal to the old tea, with the advantage of fresher soil, and the fields opened this and last year are relatively equally good.

There is a small bungalow on the estate near the factory, and a larger one of permanent character lately built, above the young tea, at an elevation of 1,600 feet, affording a cool, healthy climate. The factory is a moderate sized building, all of wood, with an upper floor large enough for current requirements but will soon require enlarging; the machinery consists of a "rapid" roller, a Davidson's "Sirocco," and an 8-h.p. engine to drive the machinery. Another roller is, I understand, being sent to the estate, to provide for possible accidents occurring to the present roller.

There are ample "Lines" for the labour force.

Forest.—This consists of magnificent jungle, having soil, so far as I can judge, equal to the land already opened,

Labour.—Coolies are obtainable in abundance, and their rate of pay is much lower than in Ceylon.

Valuation.—I consider the property worth at present as follows:—

50 acres	Old Tea	R550 =	R27,500
46 "	2 years up.	400 =	18,400
15 "	1 "	250 =	3,750
10 "	New clearing & nurseries	125 =	1,250
1,380 "	Forest	35 =	48,300
			R99,200

inclusive of buildings and machinery, as necessary and component parts of the estate.

Taking the yield already given by the old tea and the grand growth of the two-year-old tea, I have no hesitation in saying that an average yield of 500 lb. as a *minimum* can be relied upon; with the low cost of work this yield should permit of the tea being put on board ship in Quilon at 30 cents per lb. assuming its market value f.o.b. to be as low as 46 cents (of a rupee) per lb. there is a profit of 16 cents per lb. this on a seven years' purchase fully bears out my valuation as given above, and judging from my Ceylon experience I believe the tea could be put on board ship in Quilon at probably 27 or 28 cents per lb.

F. M. Mackwood.

Colombo, April 18th, 1889.

SISAL OR ALOE HEMP.

WHO IS TO BEGIN THE NEW INDUSTRY IN CEYLON?

When bales of sisal (aloe) fibre from the Bahamas realize from £45 to £50 a ton in London, according to whether the fibre is machine, or hand cleaned, it is time Ceylon colonists tried shipments. The advice given by experts to Bahama planters is as follows:—

"Be very careful to see that the fibre is cleaned and fairly packed—no stained or damaged material being mixed with the good. It would be better if the bales were of uniform weight, say either 4 or 5 cwt each. Exact weight bales of this size can be made up by weighing the fibre before packing, and sales are more readily effected when the bales are of exact weight."

Of what the trade is doing for Yucatan on the Central American coast we have the following account:—

"To give an idea of the importance of henequen (sisal hemp), over 100,000 bales will be exported for the first six months of this year, representing a value of over 5,000,000 dols. Last year's export reached 214,069 bales, weighing over 76,000,000 lb., and of a value of over 10,000,000 dols. gold. You can therefore easily realise how an article grown from the soil, with little or no cost attached to it, selling now at the rate of £50 to £55 per ton must enrich Yucatan, which, all told, has not a population of more than 300,000 inhabitants. Yucatan, in fact is now so prosperous that money is a drug; people do not know what to do with it, and they are willing to buy all kinds of goods, even the most costly. As I said before, here is a most favourable field for English commerce."

QUININE IN INDIA.—The Madras Government having directed the sale of Naduvatam quinine by village officers in small quantities of a quarter and half an ounce, Collectors have been asked by the Board of Revenue to see that the medicine is brought prominently to the notice of villagers especially those residing in feverish tracts. The bottles which contain the drug, are to have labels affixed giving the price and the quantity to be taken both in English and the vernacular of the district.—*Madras Mail*.

* In another year these three clearings, with the wonderful growth in Travancore will be worth R150 per acre more.

THE FIBRE INDUSTRY.

RAMIE OR RHEA.

(*Boehmeria nivea*, Hk. & Arn. *Boehmeria nivea*, var. *tenacissima*, Gaud.)

Readers of the *Kew Bulletin* will have noticed that considerable attention has been devoted in its pages to the subject of the present note. The previous history of Ramie or Rhea, and of the various efforts that have been made in recent years to render its valuable fibre available for commercial enterprise, have been already fully summarised (*Kew Bulletin*, 1888, pp. 145-149; pp. 273-280; and pp. 297-298). During the present year interest in Ramie appears to have become more and more general, and judging by the correspondence addressed to this establishment the subject is followed with keen interest at home as well as in India and the Colonies.

In connexion with the Paris *Exposition Universelle*, 1889, a special series of trials was held of machines and processes for decorticating Ramie (*Exposition Universelle: Essais spéciaux de machines et appareils pour a decortication de la Ramie*), and at the request of the India Office, and in continuation of similar action taken last year, Mr. D. Morris, F.L.S., the Assistant Director, was appointed to represent this country and to prepare a report of the results. This report, with the permission of the Secretary of State for India, is reproduced below:—

Royal Gardens, Kew, October 26, 1889.

A series of interesting trials of machines and processes designed for the decortication of Ramie was held by the French Minister of Agriculture at Paris in 1888, and a report on the subject, which I had the honour to prepare for the information of the Secretary of State for India in Council, was published in the *Kew Bulletin*, 1888, pp. 273-280.

These trials were resumed this year as an integral part of the *Concours spéciaux des instruments agricoles* of the *Exposition Universelle*, and opened on the 23rd September last. The jury consisted for the most part of the members of the Commission of 1888. The attendance of foreign representatives was considerably larger than in 1888, and the greatest interest was manifested in the proceedings by a large concourse of visitors.

The machines and processes this year were confined to those which had been shown as a regular part of the general exhibition. As will be seen later, all the competitors were French, and this in spite of the fact that more than a dozen machines and processes have lately been designed in this country, which are now in course of being carefully tested.

In my previous report it was pointed out that amongst the French there was attached an importance beyond their value to machines for cleaning Ramie in the dry state. I ventured to express the opinion (p. 278), that as regards India and our own Colonies it was essential that Ramie machines and processes should be competent to deal successfully with the green stems and not the dry; and that until this end was gained Ramie fibre would, I feared, continue to remain unavailable for commercial enterprise. At the recent trials this was all changed. It was a noticeable feature throughout the proceedings this year that no importance whatever was attached to the decortication of dry Ramie stems. The trials were entirely confined to results obtainable with green stems, and in order to make them still more applicable to field operations some of the stems were supplied freshly cut with leaves and some without leaves.

The following six machines and one process were submitted to the jury:—

1. E. Armand—Paul Barbier, 46, Boulevard Richard-Lenoir, Paris.
2. P. A. Favier—Société la Ramie Française—14, Rue Saint-Fiacre, Paris [for treatment of dry Ramie stems].
3. P. A. Favier—Société la Ramie Française—14, Rue Saint-Fiacre, Paris [for treatment of green Ramie stems].

4. Norbert de Landtsheer, 2, Place des Batignolles, Paris [large machine].

5. Norbert de Landtsheer, 2, Place des Batignolles, Paris [small machine].

6. Félicien Michotte, 43, Rue de Saintonge, Paris.

7. Ch. Crozat de Fleury et A. Moriceau, Villiers-le-Bel, Seine-et-Oise [process for the treatment of green Ramie stems in the field].

BARBIER MACHINE.

The machine of M. E. Armand, constructed by Barbier, and more generally known as the Barbier machine, was in every respect the same as that tried in 1888, and described in my previous report. It is constructed to be worked by hand or by steam power. It weighs 625 kilos, and the price is 487. The construction of the machine is comparatively simple, and consists of a number of cylinders and beaters with a reverse action attached. This latter allows the stalks to be withdrawn when about five-sevenths cleaned, and of the other ends being put in to complete the operation. The disadvantage of this method, as regards time and output of ribbons, is more fully discussed under the De Landtsheer (small) machine. During the trials this machine caused a considerable loss of fibre, carried away with the pith and wood. In the first trials 10 kilos. of green stems without leaves were passed through the machine in six minutes. The result was 1300 kilos. of wet ribbons of fair quality. This would be at the rate of 130 kilos of wet ribbons per day of 10 hours; or of 96 pounds (avoir.) of dry ribbons for the same period.

In the second trials 24 kilos. of stems with leaves were put through the machine in 10½ minutes. The result was 1200 kilos. of wet ribbons of moderate quality. This would be at the rate of 68500 kilos. of wet ribbons per day of 10 hours; or of 50 pounds (avoir.) of dry ribbons for the same period.

Taking into consideration the cost of this machine and the power necessary to drive it, the outturn of ribbons is much too small to prove remunerative, and the machine in its present form is useless. Better results than these have been obtained by decorticating Ramie by hand.

FAVIER MACHINE.

Two machines were shown by M. P. A. Favier whose name is well known in connexion with the Ramie industry. Machine No. 1 was designed for the decortication of green Ramie stems, while Machine No. 3 was designed for the treatment of dry stems. In this report the remarks apply only to Machine No. 1. This machine was 2 m. long, 80 cm. broad, and weighed 800 kilos. The price was not stated. It required three-quarter horse power to drive it, and two persons to feed and receive the ribbons. The machine is adapted to be worked by four persons, but at the trials, owing to want of space, it was worked with only two persons. M. Favier stated that it was designed to produce ribbons entirely free from wood and pith, ready to be converted by a chemical process, also by the same inventor, into the finest filasse ready for weaving. In outward appearance the machine was a long narrow iron box furnished with numerous small cylindrical crushers and beaters. These were entirely covered by a number of movable iron sheets, which both protected the intricate system of cylinders and prevented the escape of dust and debris. The feeding apparatus consisted of a long narrow trough, in which the stems were arranged in lots of four to six and fed to the machine at two apertures leading to the rollers. The first pair of rollers was furnished with fine corrugations to grasp the stems and pass them on to a somewhat complicated system of crushers and beaters. The ribbons passed continuously through the machine, and were ultimately delivered into the hands of a workman at the other and perfectly free from wood and pith. In the first series of trials 10 kilos. of green stems without leaves were passed through the machine in 4½ minutes. Once or twice some of the ribbons were caught in the rollers and the machine had to be stopped. The time occupied in these stoppages was not counted. The wet ribbons yielded by 10 kilos. of stems weighed 2820 kilos.

This would be at the rate of 376 kilos. of wet ribbons per day of 10 hours; or, 276 pounds (avoir.) of dry ribbons for the same period. In the second series stems, more or less with leaves, weighing 60-350 kilos. were passed through the machine in 18 minutes. They yielded 18-100 kilos. of wet ribbons. This would be at the rate of 603 kilos. of wet ribbons per day of 10 hours; or 443 pounds (avoir.) of dry ribbons for the same period.

The ribbons in both cases were well cleaned. There appeared to be no waste. The *débris* under the machine consisted almost entirely of wood and pith.

These results I regard on the whole as satisfactory.

The somewhat intricate character of the various parts of this machine would be against its general use by planters in the Colonies, but there can be but little doubt it is a great advance on most other Ramie machines now available. It might, however, be adapted for use in central factories or *usines* where skilled labour would be obtainable, and for this and similar purposes the Favier machine may be recommended.

MICHOTTE MACHINE.

The Michotte Machine, called "La Française," at first glance resembled the Barbier and De Landtsheer (small) machines. It was driven by steam power, and consisted of a pair of large rollers, each furnished with helicoidal grooves running their whole length. The large rollers first crushed the green stems and then passed them on to beaters with movable bars intended to get rid of the wood and pith. In the first trials, 7 kilos. of green stems were passed through the machine in 1½ minutes, yielding 1 kilo. of badly cleaned ribbons. In the second trial 17,400 kilos. were passed through in 2½ minutes, yielding 6 kilos. of similar ribbons. In both cases the ribbons were mixed with crushed and mangled stems, full of wood and pith. The fibres were also cut transversely (probably by the helicoidal grooves) and rendered useless.

This machine in its present state possesses no merit whatever. It is difficult to realise under what circumstances it could have been entered for trial.

DE LANDTSHEER MACHINES.

M. de Landtsheer exhibited two machines. The small machine was very similar to that exhibited by him in 1888, but meanwhile it had received some slight modifications intended to accelerate its movements. It was driven by steam-power and required two men to attend to it. It had a horizontal feed plate, and consisted of a series of rollers and beaters which received eight or ten stems at a time. These were cleaned for about five-sevenths of their length, and by a reverse action (operated by a long handle pushed by the workman) they were then withdrawn and the other ends put in and cleaned. It will be noticed that each lot of stems, under this arrangement, had to be presented twice to the machine before they were cleaned. This involved a considerable loss of time and reduced the daily outturn of ribbons. In the Favier machine, as also in the De Landtsheer large machine, this difficulty has in a great measure been overcome. The De Landtsheer small machine was used for green stems in the second trials only. In these 24,400 kilos. of stem, with leaves, were passed through the machine in 10 minutes. The yield was 6,500 kilos. of wet ribbons of good quality. This would be at the rate of 390 kilos. of wet ribbons per day of 10 hours; or 286 pounds (avoir.) of dry ribbons for the same period.

In the first trials this machine was used by de Landtsheer to complete the cleaning of ribbons previously passed through the large machine. In this instance 15 kilos. of partially cleaned and wet ribbons were passed through the machine in 6¾ minutes. The yield was 10,500 kilos. of excellent fibre worth, according to the opinion of experts, about 70 to 80 centimes per kilo.

The large machine of M. de Landtsheer, like the Favier machines, had a continuous movement by means of which the stalks passed through the machine, without withdrawal, and the ribbons were delivered at the other end ready for drying. This is an important point gained. Indeed, this was the principal improvement

noticed in the machines presented at the Paris trials of 1889, and in all in which it had been adopted there was a marked increase in the outturn of ribbons. M. de Landtsheer's large machine consists of two pairs of cylinders. The first pair is furnished with grooves opposite one another, while the second have the grooves alternate. Beyond these are two sets of beaters (*batteurs à ailettes*) which break and get rid of the wood and pith and deliver the ribbons on a revolving stage placed beneath, whence they are quickly picked up by a workman and laid on one side. The particulars of weight and price of this new machine were not obtainable. It was driven by a two-horsepower engine and required two men to feed it and remove the ribbons.

In the first trial 36 kilos. of stem without leaves were passed through the machine in 2½ minutes. They yielded 10 kilos. of wet ribbons, but these ribbons had a considerable quantity of pith and wood lightly adhering to them, and in one instance the amount of wood and pith probably reached 20 to 25 per cent. of the gross weight. Taking the yield of wet ribbons as they left the machine, the 10 kilos. above mentioned would be at the rate of 2,400 kilos. of ribbons per day of 10 hours; or of 1,763 pounds (avoir.) of dry ribbons for the same period. Even allowing for the presence of pith and wood, which, when dry, might be removed by a light shaking or scutching, it is evident that this machine will prepare more than half a ton of dry ribbons per day. It is not at all improbable that M. de Landtsheer will be able to effect some further improvement in this machine. In any case the machine is worthy the attention of planters, who with a single instrument could work off about 50 tons of green stems per week. This is an exceptionally good result, and it serves to show what progress has now been made in perfecting machines for treating the Ramie plant on a commercial scale.

In the second trials 46 kilos. of stems with leaves were put through the machine in 1½ minutes. The result was 15 kilos. of wet ribbons (with particles of wood and pith adhering to them as before). This would be at the rate of 783 kilos. of wet ribbons per day of 10 hours; or of 575 pounds (avoir.) of dry ribbons in the same period. There is a considerable difference between the results obtained by this machine in the first and second trials. This was also noticeable in the Barbier machine. The construction of these machines evidently does not enable them to cope with stems with leaves attached. On the other hand the Favier machine did better with stems with leaves than those without leaves. This, however, is not a matter of great importance. In the field the leaves could be easily detached during the cutting; and if not removed then, they would fall off of their own accord after lying in a heap (inducing a slight fermentation) for a few hours.

FLÉURY-MORICEAU PROCESS.

Only one process was shown. This was singularly simple, and consisted of steeping the fresh (or dry) stems for a short period in boiling water and removing the ribbons by hand. An open galvanised tank about 6 feet long, 2 feet wide, and about 4 feet deep, filled with water, was raised on bricks (or stones) about 18 inches from the ground over an open fire. When the water had reached boiling point a crate containing 50 to 100 fresh stems was lowered into it (and depending on their age and character) left in it for 5 or 15 minutes. At the end of that time the crate was lifted out, the stems left to drain while another lot was put in. The stems already steeped were then taken up by a couple of workmen and quickly and effectually cleaned by hand. The action of the boiling water had apparently thoroughly loosened the attachment of the cortex to the wood and ribbons were produced perfectly clean and regular, and apparently without any loss of fibre.

This method was tested in the first trials only. The operation began by placing 18 kilos. of fresh stems in boiling water and allowing them to remain there for 10 minutes. In 36 minutes (or in 46 minutes including the time occupied in immersing

the stems) the workmen, apparently not specially trained in the work, produced 5-600 kilos. of excellent ribbons. This would be at the rate of 73 kilos. of wet ribbons per day of 10 hours; or of 161 pounds (avoir.) of dry ribbons for the same period.

This process, it will be noticed, is of the simplest possible description. The only apparatus necessary is a tank. This tank could easily be moved from place to place in the field, and the wood of the stems after the ribbons are removed would probably furnish most of the fuel necessary. The process can, however, only be utilised in a few special countries where labour is very cheap.

M. Crozat states that ribbons produced by this process can be dried, baled, and delivered ready for shipment at a cost not exceeding 8 to 10 centimes per kilo. (about 85 shillings per ton). In Tonkia it could be done for even less than this.

It will be noticed that the Fleury-Moriceau process follows somewhat on similar lines to that of the Favier process of 1882. In this latter the stems were steamed for some time in a close fitting cylinder. The former is, however, much simpler, and requires absolutely no skilled labour, nor any plant except an open tank, large or small, according to the circumstances of the grower.

The inventors of the Fleury-Moriceau process are evidently of opinion that wherever cheap labour is obtainable it is in every way preferable, in the production of Ramie ribbons, to the best machine. After all, placing the Ramie stems in boiling water is only a modification of the old retting process practised so long by the Chinese, and by means of which probably the China grass of commerce is still produced. In any case the Fleury-Moriceau process deserves to be carefully considered, and especially in its applicability to the circumstances of India. There the ryots might grow Ramie in small areas, prepare the ribbons and sell them to merchants for export, or to a neighbouring factory or *usine*. The steaming process of M. Favier, designed for use under similar circumstances, failed no doubt on account of the restrictions placed on the use of the patent, and the uncertainty of the demand for ribbons. The Fleury-Moriceau process re-opens the question under circumstances much more favourable, and the subject is one which deserves careful consideration wherever labour is sufficiently abundant to permit of ribbons being produced at a price that will compete with machine-cleaned ribbons.

The relative value of the several machines, and of the Fleury-Moriceau process, tried at Paris in 1889, may be gathered from the following tables:—

TABLE 1.—FIRST SERIES OF TRIALS. Green stems, without leaves.

Machine.	No. of Hands employed.	Weight of Green Stems. (Kilos.)	Time employed.	Quantity of wet Ribbons produced. (Kilos.)	Estimated Quantity of Dry Ribbons producible in a day of 10 hours (pounds Avoir.).*
Armand-Barbier ...	2	10	6 m.	1'300	96
Favier (No. 1) ...	2	10	4½ m.	2'820	276
Michotte ...	2	7	1½ m.	1'000	—
De Landtsheer (large machine) ...	2	36	2½ m.	10'000	1,763†
Fleury-Moriceau process... ..	2	18	46 m.	5'600	161

* In preparing this estimate the wet ribbons are calculated to yield one-third of their weight of dry ribbons, and the kilo. is taken as equivalent to 2·204 pounds avoir.

† This large yield of ribbons must be reduced about 20 per cent. on account of the pith and wood lightly adhering to them.

TABLE 2.—SECOND SERIES OF TRIALS. Green stems, with leaves.

Machine.	No. of Hands employed.	Weight of Green Stems. (Kilos.)	Time employed.	Quantity of wet Ribbons produced. (Kilos.)	Estimated Quantity of Dry Ribbons producible in a day of 10 hours (pounds Avoir.).
Armand-Barbier ...	2	26	10½ m.	1'200	50
Favier (No. 1) ...	2	60·350	1½ m.	18·100	443
Michotte ...	2	17'400	2½ m.	6'000	—
De Landtsheer:					
(a) Large machine	2	46	11½ m.	15'000	575
(b) Small machine	1	24'400	10 m.	6'500	287

AWARDS OF THE JURY.

As was the case last year, the official report of the jury will probably not be published till the appearance of the December number of the *Bulletin des Agriculture*. In the meantime it may be mentioned that the jury, following the rules applicable to the other exhibits at the Exposition Universelle, awarded a gold medal to M. Favier; a gold medal to M. de Landtsheer; and a silver medal to MM. Fleury-Moriceau. These awards, it will be noticed, follow closely the results already detailed above, and they may be accepted as affording a clear indication of the relative value of the several machines and processes submitted to the jury.

To those generally interested in Ramie culture it may be mentioned that the trials of 1889 have proved much more favourable than those of 1888, and the subject is evidently ripening for solution in many directions not thought of before.

This can be best shown by a comparison of the results as follows:—

TABLE 3.—RESULTS obtained in 1889 compared with those obtained in 1888,

Machine.	Quantity of Dry Ribbons producible in a day of 10 hours (pounds Avoir.) working on Green stems.	1888.	1889.
De Landtsheer:			
Large machine	—	—	1,763*
Small machine	120	—	287
Barbier	71	—	96
Favier, No. 1	—	—	443
Fleury-Moriceau	—	—	161

It will be noticed that the best results obtained in 1888 were at the rate of 120 pounds of dry ribbons per day of 10 hours. This was with the De Landtsheer small machine. In 1889 this machine, with improvements, produced at the rate of 287 pounds of dry ribbons (more than double the quantity) for the same period. With the large machine (make due allowance for the pith and wood lightly adhering to the wet ribbons) the returns of dry ribbons would be at the rate of over half a ton per day.

OTHER MACHINES AND PROCESSES.

Before closing this report it is desirable to pass under review a few of the machines and processes not represented at Paris which have recently come into notice in this country and elsewhere. In the absence of carefully arranged public trials under the control of men thoroughly conversant with the subject, it must be understood that it is impossible to express an authoritative opinion as to the merits of such machines and processes. They are noticed here solely for the purpose of furnishing a more or less

* See note in Table 1.

complete record of Ramie experiments which have been undertaken during the present year, and of affording information that otherwise would not be available to persons interested in the subject in India and the Colonies.

THE DOTY SYSTEM.

A system brought forward by Captain Doty (inventor of the Doty light) is based on the assumption that no decorticating machine, however meritorious, will fully meet the requirements of Ramie planters, who are obliged, with the aid of unskilled labour, to deal with a large quantity of green Ramie stems within a short time. Captain Doty is of opinion that where labour is cheap women and children might be employed to strip the fibre from the freshly cut stems by hand, and leave 80 per cent. of the weight of the crop (the wood) on the field. Under such circumstances the ribbons alone would be carried away, either to be dried for exportation or to be treated at central factories or *usines*, firstly by a process of fermentation, and subsequently by chemical cleaning and washing to produce filasse ready for spinning.

"Notwithstanding," says Captain Doty, "the failures of all previous attempts to deal with this fibre by fermentation it is almost self-evident that a fermentive treatment is the only possible solution of the problem. No mechanical process that can be devised will ever eliminate the gum by which the fibres are cemented together, and without the elimination of the gum the division and sub-division of the fibres necessary to produce a delicate filasse can never be obtained."

A trial of the Doty system recently took place near Rome, and a report thereon was prepared by Signor G. Trombetta, Secretary to the Italian Ministry of Agriculture, and published in the *Bolletino di Notizie Commerciale*, Sept. 1st, 1889, pp. 689-690. In this report it is stated that the system is based on the disintegration to which the gummy substance in the Ramie ribbons is exposed by an acid fermentation. The ribbons are first of all tied up in bundles and placed in fermenting vats, where they remain for about a week. They are then taken out and washed. Afterwards they are boiled with certain chemical ingredients for two hours, washed in cold water, and dried and combed. The report concludes by stating that the fibre was in some cases of unequal character as regards colour and quality, due to the provisional nature of the appliances used; but the results obtained on a small scale gave hopes that with larger quantities and suitable boiling vessels, properly closed, and with proper machinery to agitate the mass, the fibre would be obtained in a more satisfactory condition.

THE TILL MACHINE.

As far as can be gathered from a description privately communicated by the inventor (Mr. C. G. Till), this is a large machine, weighing nearly two tons, driven by steam-power, and costing about 150*l*. It is furnished with rollers and beaters, about 3 feet long; it has a continuous action, similar to the Favier and De Landtsheer (large) machine, and takes about 36 stems of green or dry Ramie at a time. It has not yet been fully tested for the output of ribbons, but the inventor estimates that it will clean between half-a-ton and a ton per day.

PAPLEUX SYSTEM.

In consequence of letters which appeared in the *Melbourne Argus* at the time of the Centennial Exposition held at Melbourne, inquiries were addressed to Kew respecting the Papeux system for cleaning Ramie.

This system was at one time in operation by Messrs. W. H. Spencer & Co., of Hitchin, Herts, but is now abandoned. Recent experiments have been carried on with a formula invented by Messrs. Spencer themselves, and by means of this they have been successful in preparing small samples of fibre of excellent quality. It is probable that Messrs. W. H. Spencer & Co. will eventually be able to treat Ramie ribbons on a large scale and convert them by me-

chanical means into filasse or finished yarns. It is understood, however, that at present the process is not available to the public.

PLAISIER MACHINE.

A machine, the invention of a Dutch engineer named Plaisier, is the subject of an extended notice in *de Indische Mercur* of the 19th January 1889, by Van Gorkom. This machine, driven by an engine of 1½ horse-power, has been successfully worked at Deli, in Sumatra, for some months, and it is stated to treat 5,000 kilos. of green stems per day, yielding 125 to 150 kilos. of ribbons.

GENERAL REMARKS.

In the Diplomatic and Consular Reports, Series 1889 (p. 37), there is given an account of an experimental planting of Ramie at a Colony in the Province of Santa Catharina, Brazil. This Colony obtained the first prize for a collection of Ramie fibres at the Antwerp Exhibition.

In the same Reports, No. 525, on the trade of Hankow, attention is drawn to the facilities which exist there for procuring and manipulating Rhea fibre on a large scale. The Consul adds, "it would give me much pleasure to know that a good business in this article could be started here. But until machinery for preparing it is perfected, exports would be premature."

On the 23rd August last a despatch was forwarded by the Foreign Office from the Acting Consul at Caracas, dated the 25th July 1889, giving an account, of the formation of an Italo-Venezuelan Company to plant Ramie on a large scale. Experimental plantations had already proved so successful that machinery had been imported to begin the operation of preparing the fibre.

As described in the *Kew Bulletin*, 1888, pp. 145-149 a Ramie factory established in Spain, at Torroella de Montgri, Gerona, in the neighbourhood of large Ramie plantations, appear to have proved successful. This factory employed the Favier decorticating machines. In a letter dated the 19th October 1889, Mr. Woodridge, Her Britannic Majesty's Consul at Barcelona, informs me that "Ramie is still being cultivated with important results near Torroella, and that they continue to use the Favier machines, which are believed to be the most perfect machines of their kind."

It may be mentioned that these factories are being worked privately, and probably the methods and machinery are not available to the public, except under a special arrangement with M. Favier. The fibre prepared is utilised in France, and does not come into general commerce.

In British tropical possessions, both in the East and West Indies, Ramie is being grown experimentally in the hope that some machine or process will eventually be produced to enable the fibre to enter into commerce and become a regular article of trade.

The results of the Paris trials last year naturally discouraged Ramie growers, and little if any extension of Ramie planting has taken place since that time. The results of the recent trials will no doubt be closely scanned by those interested in the subject. The first aim of planters should be to produce ribbons of good quality at the lowest possible cost. In other words, planters have to solve the question how to produce Ramie ribbons, that is, to secure the complete removal of the cortex (which contains the fibre) from the green stems, at such a cost as will prove remunerative to themselves and at the same time allow sufficient margin for the cost of converting these ribbons into filasse ready for the spinners. Hitherto the want of success in the production of ribbons has apparently been the only obstacle to the development of a Ramie industry. And probably on this account the Paris trials were wholly devoted to the production of ribbons and not of filasse. The conversion of ribbons into filasse is a subject believed to be more easily dealt with. In fact there are several systems exclusively devoted to this department which appear to accomplish it. Some machines, it is true, have attempted to produce filasse by a single process from the green stems. The result has no

been satisfactory, and it is very unlikely that this can be done with a plant like Ramie, in which the individual fibres are so completely immersed in gummy matter. Hence the subject has been divided into two parts. The first is concerned alone in the removal of the fibre in the form of ribbons from the green stems, either in the fields or in their immediate neighbourhood. The second is devoted to the treatment of these ribbons and in their conversion by chemical and other processes into flasse, or fine white silky fibres ready for the spinner. The first process will naturally take place where the plants are grown, in the Colonies or elsewhere, and machines like those of Favier and De Landtsheer, or processes like that of Fiery-Morieau, may be adopted according to the special circumstances of the planter. Sufficient progress has now been made in the working of these machines and processes to justify careful trials being undertaken with them both in India and the Colonies. If these machines or any others that may be forthcoming prove entirely satisfactory, and ribbons can be produced at a low initial cost, the question of their conversion into flasse is one which will naturally come into prominence. The conversion of ribbons into flasse will very probably, at first at least, take place in Europe, where chemicals and skilled labour are the more readily available. In some countries it may be found advisable later on to establish central factories or *usines* on the spot (to save freight charges on the ribbons), and ship only the flasse to Europe. In any case once a Ramie industry is well started, there can be no doubt numerous countries will seek a share in it, and only those possessing special advantages for the growth of the plant, a supply of cheap labour, and good facilities for transport and shipment can hope to make it a success.

The best market for Ramie at present appears to be France. What little is imported into this country, in the form of China grass or Rhea, is bought up for the French market. In the Monthly Circular of Messrs. Ide and Christie for the 15th October 1889, China grass is quoted "quiet" at 31s. to 35s. per cwt.: and Rhea, "no business," at 14s. to 10s. per cwt.

With regard to what is known in commerce as "China grass," this is hand-cleaned fibre shipped usually from Chinese ports. It arrives in this country in small parcels, the yearly importation being only about 100 tons. It is nearly all taken up by continental buyers. Rhea is the term applied to machine-cleaned fibre, generally in the form of ribbons or half-cleaned stuff. The price is much less than China grass, and in case of large shipments would probably not exceed about 7l. or 8l. per ton. It is important therefore for Ramie planters to aim at the production of ribbons at a cost not exceeding about 4l. or 5l. at the port of shipment. Important elements in such production would be to plant Ramie only in places where the soil and climate will allow of three or four crops to be reaped per annum; where labour is very cheap and abundant, and where good facilities exist for transport and shipment.

D. MORRIS.

SISAL HEMP.

Sisal Hemp is extracted in Yucatan from several plants, but the true plant (*Agave rigida*) is one nearly allied to the Koratoo (*Agave Morrisii*), a native of Jamaica.

The true Sisal Hemp plant exists under several varieties, but the one which is most largely cultivated is of a greyish-green colour with thorny spines on the edges of the leaves (*Agave rigida*, var. *elongata*.) The Department, with the aid of the Government and the British Consul at Progresso, was able to secure one dozen plants of this variety from Yucatan, but it has proved quite impossible to obtain any more, as the plants there wish to preserve the monopoly. There are now about 100 plants at Hope Gardens, and they are being propagated as fast as possible.

Another variety (*Agave rigida*, var. *Sisalana*) was very freely distributed in the Bahamas by His Excellency Sir Henry Blake when he was Governor in that Colony. The inhabitants now see the great importance of this industry, and the Government has been induced to forbid the export of any plants for three years. This variety is of a dark green colour,

and has no spines on the edges of the leaves. The absence of spines on the edges saves trouble and expense in harvesting. There are a few of these plants in the Hope Gardens. It has been ascertained that this variety grows in the Caicos Islands, and His Excellency Sir H. A. Blake has directed that arrangements shall be made for the importation of as many as can be obtained. It is expected that these plants will arrive next February.

There is another plant which also yields a large quantity of the Sisal Hemp exported from Yucatan, namely, Silk Grass (*Purcraea cubensis*). There is already a large quantity of this plant in Jamaica, and there ought to be no difficulty in planting out a large area. However, it only yields from 2 to 3 per cent. of fibre, whereas the true Sisal Hemp plant yields 4 per cent. Another species (*Purcraea gigantea*) is the Mauritius Hemp of commerce.

Mr. D. J. Stoddart wrote a pamphlet in the year 1886, on the cultivation of Sisal Hemp, which was printed at the Government Printing Establishment but is now out of print. Mr. G. Preston was sent as a Special Commissioner to Yucatan by the Government of the Bahamas to enquire into the working of the Fibre Industry, and his Report was published during the present year.

Notes have been drawn up from these Reports for the benefit of those who have not the means of consulting them:—

Soil.—Any dry, poor land will suit Sisal Hemp, but rocky, gravelly soil is the best for the production of the finest fibre. Moist land is not suitable, nor rich land, like old Sugar Estates, for though the leaves grow well and fast, the fibre is poor and small in quantity. Shade is prejudicial, even to the young plants.

Planting.—Young plants are the best for planting out, and they should not exceed two feet in height. If the plants have to be carried a long distance, the roots should not be trimmed, but when they are planted out, the roots should be cut off down to the trunk, and the dry leaves pulled off. The plants are put out in straight rows: the distance between the rows being 12 feet, and between the plants 6 feet in the rows. There will then be about 600 plants to the acre. Roads, running perpendicular to the rows, may be formed at intervals of 10 chains. It is necessary to keep the plants at this distance apart, for if they are too close, the leaves may be damaged in high winds, resulting in great loss of fibre. Great care is taken in Yucatan to put out the plants quite upright, and stones are even placed to support them in a proper position, for they grow as they are planted.

The rainy season is the best time for planting. Stoddart gives the accompanying plan for laying out a field:—

The field is divided into three sections, each of which measures 1 chain, and is represented as follows—

A to B first section, B to C second section, C to D third section; in the middle of each runs an interval of proper width having a depth on either side within each section of about five chains. The short lines drawn across indicate the rows of hemp between which the cutter works, and their fore has—while cutting in any section—a distance of not more than five chains to carry the leaves to the interval, where the cart gets loaded. Each section has its boundary line as is shown from B to E.

Culture.—The culture is extremely simple. No shade of any kind is allowed, bush is cut down, and trees taken up by the roots. The young suckers are taken off, and if they are not required for planting out, they are burnt. Any plant of quite low growth may be planted between the young plants to give "catch crops." When the plants are about two years old, cattle may be turned in to keep the grass low, and to prevent bush springing up. Sisal Hemp plants thrive better without either hoeing or ploughing. Various estimates have been formed of the duration of these plants, but at any rate they last from 12 to 20 years. When they show signs of dying off, new suckers are planted between and thus there need never be a vacant spot in the plantation.

Harvesting.—When the leaf is ready for cutting, it will have inclined downwards to a horizontal position, and its colour will have become darker. Cutting should commence from the bottom, and the leaf must be taken off clean and as close as possible to the trunk. As soon as the leaf is cut, the prickles on the edges and point should be trimmed off. The leaves are then made up point and base alternately, into bundles of fifties for delivery at the works. Thirty such bundles are a day's work but of course more can be done, if the variety is cultivated without the prickles on the sides of the leaves. The bundles are placed on the edge of the cart-road, 30 bundles being a load for a dray. The workmen are paid so much per 1,000 leaves.

The time required for the leaves to ripen after planting varies, according to soil and situation, from 2 to 3 years.

Extraction of Fibre.—The fibre should be extracted from the leaves as soon as they are brought in. If left for more than 2 or 3 days after cutting, the fibre is spotted.

When the fibre is extracted by passing the leaf through the machine, it is hung on drying stands in the sun for about 2 hours until it is quite dry. If rain comes on, the fibre must be hung up under cover, or it will become discoloured. In wet weather a fire is kindled to warm the drying house, or operations are suspended.

The fibre is often bleached by leaving it on the drying stand for 54 hours after being dried, but it requires to be constantly turned. The fibre is improved in appearance, but weighs less.

The drying stand is made by erecting posts 4 feet high and fastening rails or wire on the top from one to another.

The refuse from the leaves is dried in the sun and burnt.

Particular attention is paid in Yucatan to the operation of baling, and all discoloured fibre is separated and packed as a second quality. Even the cordage used to cord the bales of first quality must be of the same kind. The bales are passed either by a screw or a hydraulic press, and great care is taken to make the bales neat looking and of uniform weight.

Machinery.—One fibre machine is required for every hundred acres of plants.

Preston says:—"The first farm I visited, 'Chenkj,' was running 6 of Death's fibre machines or wheels 50 inches in diameter, 8 inch face and 8 knives or scrapers, driven by No. 7281 10 h. p. Marshall, Sons & Co.'s stationary engine, and each wheel was cleaning the leaves at the rate of 20 to the minute or 8,000 per wheel for a day's work. Two men at each wheel, standing between the wheel and rack containing the leaves, feed the machines as fast as their hands can move—one coy to two wheels supplies the

feeders, and three others carry away the fibre to the drying ground adjoining. It is the most simple thing possible, requiring no skilled labour. There is no water used either for soaking the leaves or washing the fibre, which after exposure to the sun for two hours, is fit for baling. The engine is driven by an Indian.

"Many of the engines are supplied by Brown and May and the wheels are all from Death and Ellwood, Leicester. There are in the State of Yucatan very many machines and many engines, but no hand power machines. The machines or wheels at present in use have been working ever since they were first introduced 20 years ago: the knives or scrapers require renewing occasionally.

"The working hours at this farm were from 4 a.m., to 12 noon, or earlier, if the 8,000 leaves to each machine were cleaned with an interval for breakfast. The fibre is all housed the same day, the machine men in the afternoon lending a hand in gathering it in from the drying ground. If the farm has a press it is properly baled; if not, it is hand-baled and sent to Merida at once, 8 bales on a dray drawn by six mules, or by road and railway from the more distant farms and there re-baled or sold as it is.

"Here was a farm cleaning daily 48,000 leaves or 72,000 lbs., of the crude material yielding 3,600 lbs., (5 o/o fibre) costing at the farm 2½ cents per pound Mexican silver (33½ below gold) worth in Merida 10½ cents gold. . . . There are in Yucatan some 200 henequen farms of all sizes, the largest running 30 machines and employing 500 hands, and several others of 20 wheels or more. Many farmers' daily incomes are \$500 to \$2,000 clear profit."*

Yield.—Each plant should produce 30 leaves in the year. If there are 600 plants to the acre, this gives 18,000 leaves per acre per annum. One thousand leaves weigh about 1,500 lb., and, yielding about 4 per cent. of dry fibre, give 60 lb. of hemp. Thus, each acre should yield about half a ton of hemp per annum.

The following quotations are taken from a recent number of the "British Journal of Commerce."—

<i>Fibre.</i> —Algerian, curled, green,	per ton	£7 0 0

The following is of importance in connection with this subject:—

Washington, Sept. 27.—A copy of resolutions, adopted at the Republican Convention of Pratt County, Kan., on September 7, will be presented to President Harrison tomorrow. The resolutions substantially say that the duty levied on imported fibres, suitable for making binding twine, has failed in its protective features to develop or give the farmers a home product to take the place of the foreign fibres, and that American grain-growers are compelled to rely on imported fibres of which to make binding twine suitable for binding grain. To continue collecting a duty on such imports is working a hardship on the grain growers by increasing the cost of their binding materials.

Congressman S. R. Peters was requested to frame and introduce a bill into Congress to place all raw

* Mr. Kennedy, of the Railway Work Shop, is engaged in the improvement of his Fibre Machine, and it is hoped that it may turn out a great success.

fibres that are used and are suitable for making binding twine on the free list, and to use every means is his power to have the bill passed at the earliest possible date. The President was petitioned to call the attention of Congress to the matter, asking immediate relief.

TEA MAKING AND OOLONGS IN HAPUTALE.

The manager of Gonomotava is good enough to inform us that—"Last November a break of 'Oolong' tea made here sold in London at one-and-sixpence a pound; black tea sold at the same time and made from leaf plucked in the same way averaged 1s 2d or 4d per pound less! The enclosed is a report from Mincing Lane Brokers:

"The samples of Oolong being practically the same, we are sending one to New York for report. There is something wanting about them, not in the appearance, which is much better than former samples, nor in the infused leaf or color of the liquor, but they lack that indescribable pungency which the Chinese Oologs possess and which we take it must be acquired by the different style of firing.

"If our Ceylon friends are really going in for Oologs would it not be worth while for them to get the Consuls of Foochow or Amoy to send down two or three experts?"

We really do not see that Ceylon planters require to learn from Chinese experts even in respect of "Oologs": surely 1s 6d a lb. is good enough proof of what can be done, and with further experience, our 'Oologs' will no doubt be pronounced 'perfect.'

THE CEYLON GEMMING AND MINING COMPANY, LD.

We are pleased to be able to state that one of our leading firms assisted by some well-known old friends of the Colony in England have successfully floated the first "CEYLON GEMMING AND MINING COMPANY," the necessary capital having been subscribed for in London and Paris.

No less than £50,000 sterling of the Company's capital, or say seven lacs of rupees, have been reserved for mining; and this is estimated to be ample to do justice to the valuable gem lands which have been, so far, secured by this Company. These include some of the best parts of the Rakwana gemming country. Mining whether it be for gems or plumbago has ever been a purely Sinhalese industry, and the promoters have done wisely in associating themselves with two Sinhalese gentlemen who are well-known not only as leading members of the Sinhalese community, but as successful plumbago mine-owners of many years' standing.

Government we feel sure will only be too ready to assist and facilitate the operations of a *bona fide* Company willing to expend so large a sum in developing the mining industries of the Island, as such extensive operations will give employment to large numbers of natives of the country; and from what we know of those connected with this Company and of the land they have secured we predict for it great success and a brilliant future. Details having only come to hand by telegraph, we reserve fuller particulars until these are confirmed by mail advices shortly due.

Meantime we may mention that considerable excitement prevails among "gemmers" at different points in Sabaragamuwa. Natives who have made little or "big" fortunes in gems of recent years are coming to the front; Mr. Joseph

Fernando is one such fortunate individual, and he had a large interest in a sale of some R17,000 worth of gems which was to come off in Rakwana on Saturday. These were found, we understand, on part of the land secured by the first Company. A Mining Manager and Machinery will shortly be on their way out and we may expect to have the operations of this, the first Company, fully under way before the present year is far advanced.

The Syndicate which has sent out Mr Barrington Brown will feel that they have been to a certain extent forestalled; but there is plenty of room for all, including the third Company whose promoters seem to be "waiting on providence." We may be sure that if success attend the early mining operations, we shall see a rush of capital if not Companies. The latest news of Mr. Barrington Brown is that along with Mr. Saunders he had passed up from Ratnapura, travelling via Everton and Boolettenne on through Rakwana district.

CEYLON UP-COUNTRY PLANTING REPORT.

Jan. 6th.

Whatever may be the future of the price of Ceylon TEA, there are people here who believe that it is destined to keep up. I heard of a contract perhaps to extend over two years, and the price for leaf fixed was 10½ cents. It is to be hoped that both the contracting parties will find this rate profitable.

We are wanting rain now, and it looks as if it were not very far off. If the N.-E. has signally failed, we have so far been spared the usual cold winds which prevail at this time. Of course we are not out of the wood, and may have more than enough of it yet, but every day less is a gain.

CACAO which has just borne is resting, and not likely to do much in the way of blossom for some months yet; trees however which have been liberally treated are full of promise, with lots of blossom now visible and to come.

COOLIES are plentiful, and sometimes difficult to provide with profitable work. The news from the Coast of a threatened famine—now happily averted I trust—is rather choking off those fellows who might have relieved the somewhat congested force by a visit to their native land: you hear more of a willingness to recruit, and of the desirability of giving out advances earlier, and in a liberal fashion than of a wish to be paid up.

PEPPERCORN.

LETTERS FROM JAMAICA:—NO. 30.

To the Editor,

WEATHER AND CROPS—BLUE MOUNTAIN COFFEE—LEAF DISEASE AND COFFEE PROSPECTS IN BRAZIL—MONSOON RAINS AND DAMAGES—MATTERS POLITICAL—THE LABOUR QUESTION—LEAVING A CERTAINTY FOR AN UNCERTAINTY—THE RAILWAY POLICY—THE FORTHCOMING EXHIBITION—PENNY POSTAGE.

Blue Mountain District, Jamaica,

For Packet of October 23rd.

DEAR SIR,—It is a long time since I last had this pleasure, but I have really not had sufficient materials with which to compose a letter: even now I fear this epistle will not be as interesting to your readers as may have been some of my previous effusions. Judging from what I read in the *Overland Observers* you kindly send me every mail, our brother planters in Ceylon appear to have suffered as much as we have here from an unduly wet spring and summer. Ever since the commencement of March we have had a great deal of wind and rain, with very few fine days in between; the [consequence is that] [we] are [in] for

short crops as the coffee in our top fields has made no blossom to speak of; whereas a very dry spring is the thing needful to produce good blossoms, and secure good crops. Some few estates may do better than others, notably those that did not do much last year, but I am of opinion that taken as a whole the produce of "bons fide" Blue Mountain coffee this coming season will be under the average. This very wet season which was at first thought to be most beneficial to the settlers has in some measure disappointed them, as the excessive wet has caused a good deal of the coffee to "go light" and die off at the ends of the branches, but the quality is good, and they must be realizing good prices for their "cherry" with ordinary Jamaica coffee, in bags, still selling from 82s to 85s per cwt. in the London market.

If it be true, as I read not long ago, that a disease *does* exist in some districts of Brazil with effects not unlike that of the leaf disease in Ceylon and the East Indies, prices are pretty sure to be maintained, and as I have more than once observed, it will not be so bad for the Brazil coffee planters themselves if nature puts a check upon excessive production, so that they may themselves realize paying prices rather than drive coffee so low by glutting the market, as to cause them to be losers, even with their large yield per acre.

Our heaviest "seasons" (or monsoon) are, as in Uva, Ceylon due in October; we were hoping that as we have already had much rain for the last seven months, we might have less than usual this month, but at the time of writing it is pouring, and looks as if it would go on for some days longer. It was just at this time ten years ago in 1879, that the last heavy floods took place, which did so much damage, and caused loss of life. God grant we may now escape a like catastrophe.

As to matters political, our Legislative Council is now in session, and is to pass some useful laws, one for a cadastral survey of the island; for up to the present time such a thing does not exist; a law for the establishment of industrial schools: the first to be started at the Hope Gardens, under the auspices of Mr. Fawcett, the Director of Public Gardens and Plantations; the institution with the help of the money collected as a Jubilee Fund at the suggestion of Sir Henry Norman of a Training Hospital for Midwives: a law relative to Pilotage, the pilots having protested against the custom of allowing captains of ships, after passing an examination to be their own pilots; and last though not least let us hope the question of Immigration may be revived. Mr. Espeut is not likely to let it lie dormant, especially as two petitions have been sent in to the Governor praying that the introduction of coolies into the island may be re-established. It is very apparent to me and many others that unless labour can be procured, many more sugar estates will have to be abandoned, and that even capitalists wishing to turn fruit growers will be unable to get the labour they need. It is an undeniable fact that the Jamaica Creole settlers, the offspring of the old slaves, are very much better off than they were twenty years ago, especially in the districts where bananas grow freely; consequently they have no necessity to work on the sugar estates, in fact many have themselves become employers of labor, so the European planter and the penkeeper find it difficult to supply their wants. I believe Government is willing to reintroduce coolies on the understanding the planter or indentor bears the whole of the expense and responsibility. Now this seems hardly fair, for by present arrangements the cooly is only bound to work five (5) years on the property for which he is indented, and may afterwards remove

elsewhere and set up on "his own hook;" but as each cooly would probably cost the planter £20 or more to import, besides paying him wages at the rate of one shilling a day, and keeping him in hospital when sick, five years appears to be too short an apprenticeship, at such a heavy cost, and it should be lengthened to ten years. Government should moreover advance the necessary funds to the planter at a reasonable rate of interest, the planter re-paying by yearly instalments: this aid should readily be rendered by Government, as indirectly the whole community must benefit by the introduction of the coolies; and the maintenance of the sugar industry which has till lately always been the staple industry of Jamaica; this, were it abandoned, would be truly most disastrous to the welfare of the island. The example of Demerara and Trinidad should be sufficient for our Government. What would those Colonies be like had not coolies been largely introduced, it is absolutely necessary that Jamaica should follow suit unless Government wishes the whole island to pass into the hands of small Creole Proprietors, and the European planter and local capitalist driven out of the island. It may be said, if there is so much work to be had in Jamaica, why do so many leave the island for such places as Colon, Port Limon and Nicaragua? Because human nature will be the same to the end of the chapter. The inducement of fabulously described high wages; the desire to make money, buy a plot of land, and become a settler, is too great; and though many, as has been fully proved, only go away to die, or return debilitated and impoverished, as so many lately did from Coon, they will still listen to the voice of the charmer, the agent who bamboozles them into leaving "a certainty for an uncertainty." The American Syndicate have not yet taken over the Railway, or paid the £100,000 cash, but I hear surveyors are busy on the proposed routes, and that Mr. Wesson, the original promoter, is daily expected. I was glad to see our new Governor, Sir Henry Blake, is of the same opinion as myself, that it would have been better for the Government to have retained the railway, and extend it gradually, as has been done in Ceylon under Government auspices; and very many who were so ready to hand over everything to "Uncle Sam," now see the folly of our handing over 1-35th part of Jamaica to the Company, and that of the best remaining virgin land in the island.

Your readers will be surprised to hear that Jamaica is about to take a rise out of her fair sister Ceylon, for we are to have an Exhibition in December 1890: our Governor is very anxious to see it carried out, as he believes it will bring Jamaica and the other islands more before the world at large and prove that "there is money yet" in the islands if people will only believe it; and that it does not follow of necessity that a man who settles in the West Indies is sure to die of yellow fever, any more than a man who lives in England is bound to be carried off by smallpox, or scarlet fever.

We are at length to have the boon of penny postage vouchsafed to us from 1st January next: it has been a long time coming, just 50 years after its adoption in England.

W. S.

THE VIOLET HARVEST.—The violet harvest in Southern France and Italy is extremely good. Three trains daily bring huge cargoes of violets to Paris, packed in light fruit baskets. The contents of the evening train are kept for Paris consumption, while the violets that arrive in the morning are sent chiefly to England. What are our own farmers about that they do not also grow violets in winter?—*Court Journal.*

THE GEMMING ENTERPRISE IN SABARA-GAMUWA, CEYLON.

RAKWANA, Dec. 30th.—Gemming operations, temporarily interrupted by the heavy rains as regards a few pits at ne, are now being vigorously carried on over all the gem fields. The deep pits on Botatenu have been productive of gems of some value. It is reported that the half of this land east of a stream has been secured by the London Company's local agents. The Everton pits are being worked by half-a-dozen lessees, one of whom, Joronis Appu, has been so fortunate as to obtain a sapphire valued at R700, but reserved for a bid of R1,000. The pits are very close to each other, but there is ample room for all those engaged to be well repaid their labor and enterprise. Mr. Symons, who is now at Springwood bungalow, has been visiting his Aberfoyle property, where, too, gems could be found in plenty, if pits were freely opened up. Rakwana gemfields have been lately visited by a prospector, who has been putting up at Ratnapura for some weeks and must by now be in Colombo. The general impression was that he was agent for the Gemming Company, but this was a mistake. He was once a Coconut Planter in Negombo and later in Jaffna, but the great collapse of the European coconut enterprize in Jaffna affected him badly, and later he was in Australia. He is believed to be agent for Mr. Siedle of Colombo, and should be well qualified to judge of land in the way of calculating the probable cost of digging up, supervision and washing, though ignorant of the natural appearance of gems, comparing him with skilled native prospectors. Considering that Mr. Barrington Brown is the only European at present in Ceylon who really has anything more than a rudimentary idea of gems and gem lands, the agents of the Gemming Company have acted wisely in securing tracts of the lands which native tradition has credited with wealth of gems, and which native gemmers are ready to expend capital and labor on. The well-known gem Notary is credited with the dictum that gemming will seldom or never pay, and that money off gems is to be obtained by buying and dealing in gems. The Notary has seldom "gemmed," and on those occasions as a rule he has been one of the most successful gemmers. His pecuniary gain from gem-dealing is well-known. If Mr. Barrington Brown visits Rakwana, great advantage should accrue to the District, as there are many lands available and some of them cheap.

RATNAPURA, Jan. 4th.—The weather is all that one wish for.

There was a large influx of visitors to the city of gems during the festive season, among them being the Hon. T. B. Panabokke and Mr. Thomas Dunuwille, the extra Kachcheri office assistant at Kandy. Mrs. Wace, the chief lady of the Province, gave a ball at her residence on the 27th December, at which amongst others these two Kandyans were present. A Gan-Arachochi was got ed to death by an elephant belonging to one of the De wales in this Province.

Yesterday the Hon. F. R. Saunders and Mr. Barrington Brown arrived here by coach, and left for Rakwana. The latter has offered R400,000 for a gem-pit belonging to Iddalmalgoda Kumaribamy; but the offer has not yet been accepted.—*Cor.*, "Examiner." ["Oh, oh!" we must say to these figures: indeed the whole story is probably apocryphal.—*Ed.*]

THE LANKA PLANTATIONS COMPANY, LIMITED.

COFFEE; TEA; CINCHONA; CACAO; CARADMOMS; RUBBER, &c.

Directors:—George Allen, Esq., R. P. Harding, Esq., Edward Pettit, Esq., Sir Herbert Bruce Sandford, E.C.M.G., James Thos. White, Esq. Agents in Colombo:—Messrs. J. M. Robertson & Co. Secretary:—Mr. William Bois.

Authorised capital, £200,000 in 15,000 ordinary shares of £10 each, and 5,000 preference shares of R10 each.

REPORT.

To be presented at the Ninth Ordinary General Meeting of the Lanka Plantations Company, Limited

to be held at the offices of the Company on the 24th December, 1889, at 3 o'clock in the afternoon.

The Directors submit their Report for the twelve months ending 30th June last, together with the Balance Sheet and Accounts of the Company made up to that date. The quantity of Coffee shipped home was 1,656 cwt., against an estimate of 2,375 cwt., and the amount realised therefrom was £7,689 11s 9d, and 11 cwt. sold in Ceylon for £39 2s, a return in crop but little better than last year's, but upwards of £1,800 more in value. The following statement shows the quantity of and the amount realised in each year since 1881:—

COFFEE CROP FROM 1881 TO 1889 AND WITH PROCEEDS.

Average Net Price 68/10½ per cwt.

The Cinchona Bark shipped has been about 45,071 lb., which has been realised, and has produced £509 9s 8d. The depression in this market continues and at present there seems but little prospect of im-

provement. The Directors are not therefore disposed to press the harvesting of this product. The quantity of Cocoa estimated was 600 cwt., but the crop only produced 423 cwt., realising £1,499 2s 11d. The Cocoa trees are now looking fairly well, and there is every prospect of the present estimate being realised. The Cardamoms also failed to produce the estimated quantity, there have been 1,515 lb. only received, which realised £133 8s 1d. The Tea received from the Fordyce, Fruit Hill, and Ampittiakande Estates has amounted to 155,620 lb. (of which 34,000 lb. only was made from purchased leaf as compared with 68,000 lb. made last year from bought leaf), in addition to which 1,947 lb. were sold in Ceylon. The proceeds of the shipments of tea to London amount to £6,318 18s 7d, and of the tea sold in Ceylon to £42 14s 1d, and it is expected that a larger return will be obtained this year without purchasing outside leaf. There was also a sale of 50,023 lb. green leaf from the estates where the Company have no factory. The Tea received last year was 171,364 lb. of which 68,000 was made from bought leaf.

The following statement shows the acreage and state of cultivation of cultivation of the Company's estates on the 30th June last:—

Estate.	Coffee	Cinchona.	Tea.	Cocoa.	Cardamoms.	Rubber and Sapan Wood.	Grass.	Pattina.	Forest.	Tota.

The Directors who on this occasion retire are Mr. R. P. Harding and Mr. J. T. White, and being eligible, offer themselves for re-election. Mr. John Smith (a shareholder) the Auditor, also retires and offers himself for re-election. The Directors in their circular of the 25th September last, issued in answer to a circular which had been recently sent to some of the Shareholders by Col. Howard, dealt at considerable length with the history of the Company and its present position, add detailed the successive changes in cultivation which circumstances over which the Directors had absolutely no control had forced upon them. They do not therefore think it necessary to say more upon that subject in this report, but as in that circular they promised to detail the changes which had taken place in the management and control of the Estates since their late manager ceased to act, they accordingly proceed to fulfil their promise. The system of management, which when the Company was started, seemed admirably adapted for insuring the best possible re-

sults (viz., general superintendence by one who had a large stake in the Company's success, assisted by one of the oldest and most influential firms in Ceylon) when Coffee was practically the only product then cultivated, appeared to the Directors to be no longer calculated to produce the most beneficial results, when a large portion of the Company's estates had been planted with Tea, the manufacture of which requires constant supervision by resident superintendents assisted by properly qualified assistants.

The Directors therefore after having given the matter their most serious consideration determined to dispense with the services of a General Manager, and to provide for constant supervision on each estate by resident Superintendents assisted as abovementioned and always upon the estates unless absent by leave of the Colombo Agents, and therefore always able to give their close attention not only to the cultivation, but to the manufacture of Tea, which is absolutely necessary to produce Tea of a good quality. In addition to this the Directors with a view to giving the resident Superintendents the advantage of the varied knowledge which a Visiting Agent going from one part of the island to another must necessarily obtain, and also with a view to obtaining periodical reports on state of cultivation and mere accurate estimates of receipts and expenditure than have been heretofore at their disposal, appointing the following gentlemen as Visiting Agents:—

Mr. Dick for Ampittiakande, Arnhal, Rappannahock, Rillamulle and Thotulagalla.

Mr. Giles Frederick Walker for Fordyce and Garbawn, Fruit Hill, Gonagalla and Paramatta.

Mr. Grigson for Yatawatte—and when this new arrangement was determined upon it was calculated by the Colombo Agents that it would not only promote a much more efficient management, but effect a saving of about R5,000 per annum in the expenses.

The Directors have no reason to suppose that the calculations then made will not prove to be correct, but until at least another year has passed it will be difficult to estimate the benefits to be derived from the new system, they will be able to speak with more confidence after the end of the current year 1889 90, when some of the benefits which are expected to be derived from the new system will, it is hoped, have ceased to be the subjects of estimates. As far as the Directors can judge everything connected with the management is going on extremely well. As new circumstances arise they are vigorously dealt with, the estimates are made with the greatest possible care, and when (as it is happened in one or two instances) such estimates have had to be reduced the expenditure has been cut down as nearly as possible to a corresponding extent. The estates are now being managed with a firm grip which is calculated in the course of another year (weather and other circumstances permitting) to produce very beneficial results. The Director do not think it necessary to say anything further on these points, but they think it may interest the Shareholders to have an epitome of the revised estimates for the year ending 30th June next.

The following is a copy of such Epitome:

ESTIMATES OF THE CROPS AND EXPENDITURE BY THE SUPERINTENDENTS FOR THE YEAR 1ST JULY 1889, TO 30TH JUNE 1890, APPROVED BY THE COMPANY'S AGENTS AND VISITING AGENTS.

PLANTING IN THE SOUTHERN PROVINCE OF CEYLON; UDUGAMA, CEYLON.

This is a small district near Galle very compact comprising the following estates:—Riseland above the river Gindura near Udugama village, and also Udugama estate. These two places lie separately from the main district. Then taking the new cart road from Udugama village you ascend and arrive at Saumarez, where there is a nice factory and machine worked by steam. This is the largest factory in the district and takes the leaf from the greater part of the district. Then passing along the cart road, you come next to Daphne, then "the Company" as it is familiarly called (Ginniedomine is the name of the estate). Taking the bridge path branching off at Ginniedomine bazaars you reach Doonebale, beyond which are Beau Séjour, and Digidolle, while lying between Doonebale, Saumarez and Ginniedomine is Indian Walk where the only clearing of the year is in progress. I have mentioned Saumarez factory, but there are besides the Doonebale factory, a converted set of lines, and the Riseland factory a neat small building. Indian Walk has just been furnished with a factory, so that there are now four factories in the district.

Beyond Beau Séjour, the cart road, now in course of metalling, leads away through forests and chena to the road between Galle and Kanaka. The road is being splendidly laid with metal and will soon be in fine order. The only complaint now is that there is so little depth of metal.

Labour.—Most estates,—in fact all,—use Tamils for the ordinary work and call in Sinhalese when pressure comes. Sinhalese get 2½ cents per lb. of green leaf. There are many Sinhalese located on the estates and in many cases the Tamil has taken unto himself a Sinhalese wife—and invariably the union has been more satisfactory than if he had a wife from among his own people. The Sinhalese is a better wife than a Tamil, being more obedient and careful with the cooking.

There is a large field in the villages from which to draw all surplus labour, and Tamils form the permanent force.

Tea Prospects.—A great part of the district having been opened in various New Products, the cream of the soil was taken off before the tea was put in and

consequently tea hangs fire at first in places; but there is hope and while there is hope we can bear up against disappointments. The younger places give good promise, but it may be well not to say too much about prospects just yet a bit.

The soil is of a nature which is favourable to tea, being free and full of iron, but a free iron soil in a blazing hot sun in the lowcountry is not calculated to do much till the roots are well down and the bushes show good cover.

The Udugama tea is of good strength, fine liquor, pungent, and delicate flavour.

The district is about 20 miles from Galle whence tea is shipped. As the crow flies the sea is about 12 miles off, and this makes Udugama the most salubrious district in the lowcountry. It had a bad name when the jungles were being opened and malaria was prevalent in newly opened land, but all tropical districts have been subject to this.

Tea can be sent to Galle by road or down the Gin-ganga to within a mile of Galle.

MAY UDUGAMA LONG FLOURISH!

[Hear, hear!—Ed.]

SOME MINOR AILMENTS AND THEIR CURES.

CHRONIC RHEUMATISM.—This condition is of such common occurrence that any detailed description of the symptoms is almost uncalled for. The joints are most frequently attacked; the knees, ankles, hips, and shoulders usually suffering severely. Sometimes the pain is worse at night, but more frequently during the day, and on exposure to wet and cold. The methods of treating this obstinate condition are many, an indication that there is no specific means of curing the disease. Turkish baths are useful, and benefit will be obtained from baths containing Extract of Pumilio Pine. When the pains are worse at night, Tabloids of Iodide of Potassium may be given, two or more twice during the day, and two at bedtime. The Tabloids of Salicylate of Soda are also useful, two or three being taken two or three times daily. As a local application, rubbing with Lanoline is recommended, whilst others prefer friction with Hazeline. In many cases a change of climate will have to be resorted to, and the patient will have to go to Ventnor, Hastings, or some other place for the winter.

INSOMNIA OR SLEEPLESSNESS.—Sleeplessness may arise from various causes. It may be due to pain, to restlessness, or to excessive activity of the brain. It is customary in many cases to take morphia; but the administration of morphia, unless under the advice of a physician, is to be regarded with suspicion. A better remedy, and one not likely to be injurious, will be found in Bromide of Potassium Elixoid, given in doses of a tablespoonful or more at bedtime. Tabloids of Sulphonal have been found almost a specific for most forms of sleeplessness, and have the advantage of producing no after-effects. Care should be taken to see that the room is properly warmed, and that the patient has plenty of bed-clothes of light kind.

SORES.—Sores on the skin are generally due to defective circulation of the part, and are excited by a blow or friction. They have a tendency to spread so as to form large ulcers. They are by no means easy to cure unless the patient will consent to rest entirely in bed. The application of bandages will often do much good, but more benefit will be obtained by the use of Hazeline locally than by any other remedy. The bowels should be kept well open and the general health and strength maintained by the administration of Dialysed Iron. The preparation made by Borroughs, Wellcome & Co. is one of the best.—*Health, London.*

MR. R. E. PINEO IN MANITOBA.

FROM CEYLON:—AN EASTERN TEA AGENT ON A BUSINESS VISIT TO AMERICA.

Mr. R. E. Pineo, a gentleman who has come to America as the representative of Ceylon tea planters, for the purpose of establishing agencies for Ceylon tea, arrived here yesterday afternoon from Vancouver. He has with him two Hindoo servants, man and wife, who travel in their native costumes, which makes them interesting objects in this part of the globe. Mr. Pineo has lived in India since 1858, and is thoroughly acquainted with the political and commercial affairs of that and tributary countries. He says that the C. P. R. is a grand route for East Indian and Australian trade for American points, and he is confident if the company establishes agencies at Hongkong for the through billing of freight that immense trade could be developed, as the route is the shortest in existence. He intends interviewing Mr. Van Horne on the subject when he reaches Montreal. Mr. Pineo is enthusiastic on the matter of Ceylon tea; he claims that it is the best flavored, purest and cleanest tea made in the world.

Mr. Pineo will establish agencies in all the leading wholesale countries of Canada and the United States, including Winnipeg. Mr. Pineo says that Ceylon is a grand country. The chief products of the country are tea, cotton and tropical fruits. The natives comprise Boers, Buddhists, Ceylonese, tamans and mongrels. Ceylon is the Mecca of the Buddhists. Mr. Pineo leaves this morning for Montreal, going via St. Paul and Chicago. This is his second trip around the world, and he has crossed the Atlantic and Pacific Oceans eighteen times.—*Manitoba Daily Free Press.*

TOBACCO: LONDON BORNEO TOBACCO CO.

The report to be presented at the first yearly general meeting states:—The number of fields planted this season is about 150. The directors had reason to believe that a larger amount of fields would have been cropped this first year, but the inevitable difficulties of starting an almost entirely new enterprise in a new country have not been altogether overcome. The company was exceedingly unfortunate whilst in the full swing of preparation to lose suddenly, by death, the services of their manager, Mr. Beuse, a gentleman who, the directors had every reason to believe, was eminently fitted to carry on the important duties of his position. Two of the European assistants were also invalidated about the same time. Unfortunately for this year's crop the British North Borneo Company, at the very moment when most assistance was required from them, found themselves, from no fault, perhaps of their own, but in consequence of a small war being suddenly forced upon them, unable to give all the assistance and protection required; moreover, the large number of desertions that took place, and the necessity of undertaking, until another manager could be obtained from Deli, the practical management of the estate, crippled the hands of our managing director, and prevented him from either planting the number of fields he had intended or of obtaining satisfactory results from the employment of the labour hired and paid for. There is every reason to expect that the difficulties previously referred to will not occur again, as a telegram just received from the managing director, dated Singapore, Dec. 9th, reports all operations going on favourably, health of colonies good, and prospects of labour supply favourable.

As opening new estates, especially on a large scale, is evidently attended with considerable risk of sickness and consequent loss, the directors have decided not to attempt to carry out the original idea of cultivating 1500 fields in 1890, but full preparations are now going on for planting about 80 fields, new managers of ability have been obtained, and the local government are doing all in their power to help the enterprise.—*L. and C. Express, Decr. 20th.*

THE BLACKMAN FAN IN TEA WITHERING.

In view of the articles which have from time to time appeared in our columns regarding the Blackman Air Propeller as adapted to our tea withering sheds, the following extracts from letters received by the Blackman Co. Ltd., and forwarded to us, will doubtless be of interest to our readers:—

I.—Extract from letter from G. O. Kentish, Esq., Taranti Tea Estate, Doorns.—“The (two 48-inch) ‘Blackmans’ are doing grandly. I will send you a report in a day or two, as requested by Mr. Aldam: but I may mention that I withered dry leaf with them in 3½ hours, and wet leaf in 8. The fans were then only running at two-thirds speed. With the greater speed I have now I expect much better results.”

II.—Extract from letter from A. S. Peuny, Esq., Dikooch Tea Estate, Cachar.—“Some time ago you asked how the two (48-inch) fans were doing, and I now have the pleasure to give you the following figures:—August 29th.—668 lb. plucked at Dixea the previous day, reached this factory at 7-45 a. m.; was spread at 8. o a. m.; and rolled at 11-30. August 30th.—580 lb. arrived from Dixea (8 miles distant) at 7-40 a. m. was spread at 8. o a. m.; and rolled at 11-45. These results are most satisfactory. Formerly the Dixea leaf had to be always kept over until the following day; no doubt, to the detriment of manufacture. A factory with ‘Blackman’ fans can, I consider, do with one half the usual number of buildings.”

III.—Extract from letter from A. A. Bull, Esq., Baracora Tea Estate, Sylhet.—“My arrangements for keeping the loft practically air-tight are not yet completed, and I have ‘gill-mills’ instead of glass windows. Although I am not able, owing to circumstances, to reap the full benefit of having them (two 60-inch Blackmans), I work them regularly and find them of great assistance in withering, even as they are, and I am very glad indeed we invested in them. As soon as glass arrives I hope thoroughly to test them.”

Several of these fans are being erected upcountry by Messrs. John Walker & Co., agents for the Blackman Ventilating Co., and one of them can be seen at the Colombo Iron Works. They cost little, says our correspondent, and are an undoubted success.

REGULATION OF SUPPLIES OF TEA.

The Indian Tea Districts Association have issued the following report of the special committee, appointed by the general committee of the Indian Tea Districts Association at their meeting held on Nov. 19th, 1889, to work out details of a scheme for regulating the supplies of tea placed on the market, with a view to prevent the depreciation in values, not infrequently caused by hurrying forward more tea than the buyers are able to deal with:—

The special committee, having had the advantage of conferring with the representatives of nearly all the leading brokers, has arrived at the conclusion that, looking to the difficulty of formulating any arrangement of a hard and fast nature, and considering the many conflicting interests involved, the object in view can be best attained by a general understanding among growers and importers and the brokers.

The special committee find that the following are among the contributing causes of a depressed market:—

1. The unnecessarily large number of separate breaks sent home by gardens, thereby harassing the trade.

2. The offering of an enormous quantity of tea for sale on a single day.

3. The printing for sale of breaks of tea before the teas are actually ready for sale in the warehouse, and consequent frequency of withdrawals from sale at the last moment.

The brokers being more fully in possession of the information necessary to enable them to exercise control over supplies, inform us that it has hitherto been their endeavour, as far as possible, to confer either to a certain extent with regard to printing,

but that more might be done by merchants themselves to support their efforts.

The brokers are accordingly recommended to endeavour as far as possible to dissuade their principals from—

1. Printing their teas for sale before all the teas of each break are actually in the warehouse, and have been bulked and worked.

2. Bringing out fresh catalogues of tea to be sold on the last days of the same week in which the catalogues are issued, when the total amount already advertised for sale appears sufficient, or more than sufficient, for the requirements of the trade.

Members of the Association are invited to do their utmost to strengthen the hands of their respective brokers, and at the same time to endeavour to attend the fortnightly meetings of the Association, on Tuesdays, at 2 p.m., to confer with one another, and with brokers, with a view to better regulation of the supplies put on the market.

Robert Lyell } Members of the
Geo. Seton } Special Com-
R. G. Shaw } mittee.

Ernest Tye, Secretary.

A meeting of the general committee of the Indian Tea Districts Association was held on the 17th inst. to receive the report of the special committee appointed to consider the question of regulating the supplies of tea placed on the market. The following members attended:—Chair—William Roberts (Jorchaub, Darjeeling, and Tiphook Companies), R. G. Shaw (Assam Frontiers Company), Robert Lyell (Geo. Williamson & Co.), R. P. Doake (Duncan, Macneill, & Co.), A. Bryans (P. R. Buchanan & Co.), J. Berry White (Jokai Tea Company), W. L. Watson (Jas. Finlay & Co.), W. N. Clark (Begg, Dunlop, & Co.), Geo. Seton (Octavius Steel & Co.), Henry Earnshaw (Alex. Lawrie & Co.), W. F. Raban (Gotoonga Estate), Arthur Thompson (W. J. and H. Thompson, and Noakachar Tea Company), Geo. White & Co., G. W. Wilson, and Stanton, Arthur Capel & Co., Stenning, Inkipp & Co.

After a very lengthy discussion the following resolution was moved by Mr. W. L. Watson, seconded by Mr. J. Berry White, and carried unanimously:—“That the brokers be requested to meet once a week, and endeavour by mutual agreement to regulate the offerings as far as possible in accordance with the demand at the time and the members of the Association present hereby pledge themselves to support them.”

It is hoped that all members of the Association and others interested will give their cordial support.—*H. and C. Mail.*

GRAPHITE IN NORWAY.—A graphite mine has been discovered at Eker, close to Hongsund, Norway. The quality is apparently good, and hopes are already entertained that this discovery perhaps may give rise to the erection of local lead pencil manufactories.—*Public Opinion.*

GEMMING IN CEYLON.—The Gemming and Mining Company of Ceylon, Limited, have issued a prospectus, with a capital of £100,000. Messrs. Delmege, Reid & Co., of Colombo and Galle, who are interested in some of the under-mentioned properties, have expressed their willingness to act as local agents, and the London board consider this a guarantee to the shareholders that the anticipations contained in this prospectus will be fully realised. The company has been formed for the purpose of acquiring the freeholds (subject to a small Government licence) of the well-known estates of Everton (native name, Kabragallakelle) and Aberfoyle (native name, Kalkanda), being a portion of some of the richest gemming land situated in the Rakwana district, Ceylon; and to provide capital for developing the properties and working the gemming pits already sunk and proven. The secretary of the Ceylon Gem and Mining Estates Syndicate, Limited, points out that his company is in no way connected with the Gemming and Mining Company of Ceylon.—*H. & C. Mail.*

COFFEE.—There was some talk about a wonderful substitute for coffee, a product of the island of Réunion. Mr. St. John, the British Consul at Réunion, has furnished a report upon these Gartneria seeds, for the plant was found to be not a new species of *Mussaenda*, but a member of the natural order *Loganiaceae*, named *Gartneria vaginata*. Mr. St. John states that they yield a pleasant beverage when roasted like coffee-berries—a beverage possessing some of the flavour of coffee, but much less fragrant. Mr. St. John further points out that the shrub is by no means plentiful upon the island, and is not so fruitful as the coffee plant. He believes that it could not be placed upon the market at a price that would either compete or compare with that of genuine coffee.—*H. & C. Mail*.

TEA PLANTING IN THE CAUCASUS.—Considerable confidence is expressed by some of the Russian newspapers in the prospects of tea planting in the Caucasus. The *Novosti* states that the plantations on the Black Sea coast between Batoum and Sukhum Kaleh are assuming the appearance of regular tea gardens. However, tea-growing is no new thing in the Caucasus, as half a century has elapsed since the first tea shrub was planted there in the public garden of Sukhum Kaleh. Prince Erstow exhibited at the recent exhibition at Tiflis a tree 4s years old, and Colonel Solovtsov exhibited other-five years old. All these were in the most flourishing condition, and, moreover, provided seeds sufficient to plant a considerable area. One of the chief drawbacks to the industry has been the necessity of importing all seeds from China, and this now promises to be obviated by the supply procurable from the public gardens and great estates of the Caucasus. French and German naturalists have declared that there is no region more suitable to the cultivation of tea than the shores of the Black Sea between Batoum and Sukhum, where the climate is warm, moist, and equal.—*London Times*. [With reference to this paragraph, following a succession of similar notices, we may remind our Russian friends that they can obtain any quantity of the seeds of a better species of tea than the China from India or Ceylon. We doubt, however, if the climate is so suitable as it is represented; while on the Black Sea shores as in the United States, the abundance and cost of labour will settle the question.—*Ed.*]

COCONUT BUTTER.—What is known in your land of coconuts about coconut butter? The mention of it in the following extract is novel to me:—

Coconut Butter.—The United States Consul at Mannheim, in his last report, refers to a discovery by German chemists in the coconut of a fatty substitute for butter. Immediately after the discovery a firm was established in Mannheim for the purpose of manufacturing the new article, to which it has given the name of coconut butter. Although in existence only a year, it is unable to meet the constant demands made on it. It employs 25 men, has a 40-horse power engine, and produces daily 3,000 kilos. of butter, which it retails at from 6½d to 7½d per lb. The nuts come mainly from the South Sea Islands. The new butter is of a clear, whitish colour, and is said to be better adapted for cooking than table purposes. It is neither disagreeable to the taste nor smell. At present it is chiefly used in hospitals and other State institutions, but it is rapidly finding its way into houses where the people are too poor to buy butter. The working classes are rapidly adopting it in place of oleo-margarines. It is said to be singularly free from acids, and to be therefore much easier of digestion. In Germany there are about 50 factories engaged in producing margarines and other artificial butters.

SAND AND GRIT IN INDIAN TOBACCO.—The Indian Government, in sanctioning the further engagement of Mr. Caine, the tobacco expert, by the Madras Government, instructed the Under Secretary to write:—

I am to take this opportunity of suggesting for the consideration of His Excellency the Governor in Council, that in the coming year careful experiments be tried by Mr. Caine with a view of ascertaining whether sand or grit, &c., are or are not taken in by the leaf while drying, this being the one fault which has stood in the way of tobacco exported from Northern India.

CACAO AND TOBACCO IN KURUNEGALA DISTRICT.—I have been in Kandy, where I spent a delightful day amongst the Peradeniya Palms. From Kandy I walked 25 miles to Kurunegala in 3 stages, stopping *en route* to see what was *once* the glory of cacao cultivators, viz. the estates round Galagedara, but which, alas, are now but shadows of their former selves. After that, I was late to see Herr Schappie and his tobacco enterprise (as it was all over for this season), but I heard that he was well content with the result of the crop and when a planter is content, one knows that he has been something more than successful!—*Cor.*, Jan. 3rd.

THE TROPICAL AGRICULTURIST MONTHLY.

Vol. IX.]

COLOMBO, FEBRUARY 1ST, 1890.

[No. 8.

THE PLANTING ENTERPRISE OF CEYLON IN 1889.

REVIEW:—TEA, COFFEE, CINCHONA CACAO, CARDAMOMS,
COCONUTS, CINNAMON, GRAIN, TOBACCO, COTTON,
NEW PRODUCTS.

TN respect of the great plantin industry of the Colony—in tea, coffee, cacao, cinchona bark and cardamoms besides minor products—we are accustomed at this time of year, not so much to look back to

to take stock of the position attained and to look at the prospect before us, giving revised estimates of the current season's exports based on the experience of the quarter expired as well as on the latest district reports. But before doing so, we may say, that 1889 has been by no means a favourable year for tea 'flushing,'—cropping—or for the planting of new fields, in respect of rain distribution and the season generally. On the contrary, in the face of the irregularity of the monsoons and the almost entire failure of the "North-east," estimates of tea crops in many districts have not been realized by a very considerable percentage and the general opinion now seems to be that our own and Mr. Rutherford's anticipation of tea export for the present seasons will be found above the mark. We have endeavoured to get the opinions of all the Inspectors of Estates in the country as well as of some other experienced planters, and taking the average of about a score of returns before us, the result will be found in the table we publish below. In the same way we give the average of estimates for the other principal staples of estates deduced from the information collected, and add finally, our "Revised Estimate" based on the respective value attached to different returns:—

		SEASON 1889-90.			
		EXPORT ESTIMATES:			
	Observer's October estimates.	Shipped up to 9th Jan.	Average of Planters' estimates received.	Observer's revised estimates.	
Tea, lb.	...42,000,000*	9,278,091 (Last year 7,448,807)	83,800,000	41,000,000	
Coffee, cwt.	90,000	27,042 (Last year 24,709)	84,500	85,000	
Cinchona Bark lb...	7,500,000	2,311,745 (Last year 3,506,877)	6,850,000	7,250,000	
Cocoa, cwt.	16,000	7,353 (Last year 2,601cwt.)	15,500	15,500	
Cardamoms lb.	... 300,000	92,489 (Last year 66,719)	275,000	300,000	

* Mr. H. K. Rutherford estimated at 43,000,000 lb.; Messrs. Somerville & Co. estimated at 42,660,000; and Messrs. Forbes & Walker at 40,000,000 lb.

In the case of TEA we are going on the fact that while one planter's estimate is so low as 30 millions (!) and another from a shrewd quarter stands at 38 millions, yet the majority of our returns are not under 40 millions, while two very experienced observers go even now as high as 42 and 42½ millions lb. respectively. There is also the fact that in the first quarter of the season—by no means considered a favourable one this time generally—we have shipped no less than 9½ million lb. We do not think, therefore, taking all into consideration that Ceylon should export to all quarters—the Colonies, America and the Mother-country—less than 41 millions during season 1889-90, of which less than 39 millions may be sent to the United Kingdom. Considering the falling-off in China exports and the fact that the Indian tea crop is below the estimate, this quantity should be readily taken off and the statistical position of our staple, especially in anticipation of a reduced imperial tea duty, must be considered very good. The year in fact opens with very encouraging prospects all round to the planter—the only little cloud at present being perhaps found in rather higher rates for rice than are usual. Here is what an experienced tea planting authority says in sending in his estimate:—

"Prospects generally are I think good. Labour is plentiful, and in some cases more than is required in the immediate present, and whenever inquired for is easily obtainable from the Coast. The number of 'permanent settlers,' I may call them, on estates has largely increased. Sinhalese take to estate life readily, and seem to have no wish to return to their villages. In nearly all cases where they are resident on the estate, they work under Tamil kanganyas, and have adopted the Tamil coolie dress and the Tamil language. They work as well and as regularly as the Tamils, and we have here a new and steadily increasing source of labour supply, at the higher as well as at the lower elevations which on all accounts we should endeavour to encourage."

TEA IN UVA.

The past year has given evidence both in yield of crop and prices obtained that (with the facilities for safe, cheap transport the railway now making will secure) there is no reason why Uva should not become a first-class tea-producing division of the country. Here is the opinion of an experienced and cautious planter in the BADULLA division and what he says of tea doing well on patana (natural grass land of which there are great reserves at a good altitudes in this province) is specially noteworthy:—

"With regard to tea prospects in Badulla district.—Tea is doing very well indeed on all places where the lay of the land is fair and where the soil is not gone, it is doing especially well on patana. We have no old tea, none I fancy much over four and half years,

But such yields as 400 lb. an acre have already been secured, 500 lb. an acre has been got, and the latter is the estimate over a large estate this season. I got 366 lb. made tea myself off a field $2\frac{1}{2}$ - $3\frac{1}{2}$ on patana land, and many places could give better figures. I have said enough to show you that there is nothing to prevent tea, climatically, (is there such a word?), doing as well here as anywhere in the island. Our tea is of good flavor, and prices of Spring Valley and Glen Alpin are encouraging, especially when you consider that a large proportion of their leaf is purchased, that all the tea is young, and that the manufacturers have all their experience to gain. I do not however think Badulla (or Haputale) will ever again be as valuable under tea as it was under coffee. Many estates in outlying parts of the district will probably not be put into tea owing to transport difficulties. If patana tea lasts, a great deal of patana land will be opened, but people would hardly for some years yet open new estates of that character. Given fair lay of land I believe tea will do as well here as in the best up-country districts of the island. Labor supply is, though not abundant, sufficient, and the Sinhalese are taking to work on estates so generally that the difficulties of clearings or other temporary heavy works are much lessened."

From both the HAPUTALE and MADULSIMA divisions, we have also had lately, exceptionally favourable reports as to quality of, prices obtained for, and yields of tea. There is therefore no reason to doubt that Uva will have ready for the Railway as much produce (in tea, cocoa and cinchona bark chiefly) as will make up for the deficiency in coffee on the estimates on which the railway financial returns were based.—We now turn to poor dethroned ex-king

COFFEE.

Uva, of course, makes up most of the miserably poor estimate of exports, with a certain quantity from the Agram division of Dimbula and the Bogawantalawa end of Dikoya.* In Uva we include Udapusselawa. We have received this season more favourable reports of the appearance and condition of individual coffee estates in all these districts, than for perhaps a couple of years previously, and not a few planters are still hopeful of keeping their best fields in good heart by careful cultivation, every encouragement being afforded them by the high prices prevailing and in prospect. Some experiments in a quiet way are being made in planting Coorg coffee seed along with shade trees after the fashion which has proved a success in Mysore; and so far we believe Mr. Hamlin of the O. B. Estates Co. is entirely satisfied with his Kondesalle fields (Dumbara) planted after this fashion within the last two and three years. Such experiments however can only be isolated ones, in certain selected localities, and unless a revival takes place in respect of planting Liberian coffee in the lowcountry—of which there is no sign, and no special encouragement to do so†—Ceylon is unlikely to be good henceforward in any season for a larger export than 100,000 cwt.; while it may fall to 50,000 before many seasons roll by, if the shade experiments do not prove permanently successful.

* The Rattota division of Matale East once a flourishing coffee-district is estimated to give only 80 cwt. this season, but there will be 240,000 lb. tea, 150,000 lb. cinchona bark and 16,000 lb. cardamoms.

† For instance, the Kalutara district first opened very much for Liberian coffee and in which 16,200 acres have been taken up by planters of which 5,800 acres are cultivated, is now practically all in tea—1 to 12 years old—giving very nearly 1 million or (950,000 lb.) crop this season. The Chairman of the district writes:—“generally speaking it may be said that tea is the sole cultivation on the 5,800 acres noted above, the cultivation of Liberian coffee and citronella grass having been practically abandoned, Cinnamon estates not included.”

CACAO, YIELDING THE COCOA OF COMMERCE.

Our estimate does not indicate much progress in this desirable product, being 1,100 cwt. below the maximum export in season 1886-87. One gentleman who makes his estimate 15,000 cwt., adds the following remark:—

“This season’s crop is very early, much more so than last year, fully a month earlier,—hence the progress in exports, as compared with last—it is not an excess of yearly yield, but only an excess up to date.” In the Kurunegala district and around G. I.agedara, while there has undoubtedly been failure and much disappointment, we are glad to see one Superintendent, Mr. F. H. Shelley reporting in the following gratifying way:—

“I manage 330 acres of this product; and crops have been steadily progressive for the last five years.”

CINCHONA BARK.

It will not do, as some writers are inclined, to say that cinchona is practically dying out in Ceylon and that in the face of canker and other causes, there is no chance of this product continuing among our exports even on a diminished scale for many years. Such statements amount, in fact, to a slander on leading districts in Uva where the cinchona tree from well-selected seed, flourishes well and indeed in a few other favourite divisions of our planting country. It cannot be forgotten how a recent visitor, a Java planter by no means inclined to think much of what he saw in Ceylon, confessed that finer fields—some of them young—that he saw of cinchona on Cannavarella were not to be excelled in all Java. It is ridiculous, too, to say that there has been absolutely no fresh planting within the past three years in Ceylon. No good is done by such statements. Apart even from Uva, we know of promising plantings in different districts and still more of estates with abundance of flourishing coppices which in a few years will once more be yielding bark. Nevertheless, there is ample evidence that Ceylon will never again send the large exports of bark which she did in the past, unless a sudden spurt or revolution on the market, should induce an elaborate harvesting from all available trees. On the contrary, for two or three more seasons, downward the course of our cinchona exports may be expected to be. We do not think the total can be below 7 million lb. for this season, nor below 3 or 4 million lb. (chiefly from Uva and the Agram) for many years to come; but the latter figure may be reached by 1892-93. It will not do henceforward therefore to speak of Ceylon as ruling the cinchona market in Europe. Java rather is likely to take that place; but with a steadily increasing consumption, there ought to be a good demand at much better prices—ere long—for all available bark. The highest estimate sent in to us for the current season’s exports is $7\frac{1}{2}$ millions, while one is as low as five millions. In estimating, however, for a falling-off of $3\frac{1}{2}$ million lb. on last season’s exports, we feel, for various reasons, that we have gone as low as is justifiable.

CARDAMOMS.

Of this product, the cultivation continues fairly profitable, a fact perhaps due to the non-extension of cultivation on any large scale during the past few years. The highest estimate of exports furnished to us is for 320,000 lb and this by a gentleman for whose opinion we have great respect; the lowest return (from another “Old Hand”) is only 220,000 lb. We are inclined to the higher return and adhere to our original figures 300,000 lb, or practically the same export as during the past season.

SALES OF ESTATE PROPERTY.

During the past year, there has not been much movement in respect of plantation property, but

there is the prospect of more capital seeking investment in such property during 1890. The following are some of the estates sold, so far as we have been able to learn:—

District.	Estate.	Sold by.	Purchaser.
Kelani Valley	Wilton	A. J. Thackwell	Native R17,000
"	Obertsey	Ross-Wright	H. Fyler
Maskeliya...	Mousakelle	H. M. Husey	£6,000
"	Ekolsund	W. B. Seton	£5,000 to Mr. Harding
Dimbula	Ladbroke	Cantlays	A. C. White
"	Rosita	Fraser-Stephens	Jas. Hill
"	Tangakelle	Sir W. Gregory	Ceylon Tea Plantation Co. £6,500
Dikoya	Battagalla	W. Willans	Messrs. Harding and Saunders
Medamaba- nuwara	Kobonilla	"	E. J. Young
"	Horankanda & Meemunagalle	"	"
"	Waitalawa	Heirs of Thos. Hudson	Charles Strachan R4,510
Pundaluoya	Harrow and Kaluoya	Messrs. Kars- lake	Mrs. Har- man and H. Van Cuylenburg
Nuwara Eliya	Margherita	E. T. & A. A. Delmege	E. Radley A. Rogers & Co.
"	Court Lodge	"	"
Matale	Ityliadde	L. F. Kelly	J. H. Barber R3,000
Group of Estates in different districts		O. B. C. Liquidator	W. D. Bosan- quet and O. E. Rowlands

In addition to the practical reports given in our last issue in regard to COCONUT and CINNAMON prospects, we append the following from the review of our Ceylonese contemporary of the "Examiner":—

The prices now ruling for Coconuts and Oppra are in favour of the producer, and if the demand for Oil continues to be brisk, Planters will have little cause to complain. The preponderance of opinion against the idea that the leaf disease which is believed to be spreading offers serious cause for alarm, is consoling; but it should not relax vigilant and intelligent observation. A useful index would be the crops on individual Estates—whether to confirm or correct the impression that crops have been disappointing in recent years, or to ascertain how far the seasons are responsible for the retrogression, or absence of due development, if such there be. So far, the only hopeful feature about Cinnamon is that Chips are scarce. The action of the larger Proprietors has thus been successful in arresting the production of the article; but it has not yet stimulated the demand for Quills. Immediate results are, of course, not to be expected from measures such as have been adopted; but the fact remains that, locally, the prices for Quills are lower than they have been for months past. The London Quarterly Sales next month should show the beginning of, we trust, a steady advance in price, through the diminished production of the coarser bark. The demand for Plumbago continues at highly satisfactory rates, and there is no reason to apprehend a restricted demand during the year.

In respect of the GRAIN Cultivation of the island, there is no lack of progress under the stimulus given by the extraordinarily liberal—some people think extravagant—policy of the Government in respect of irrigation works and this has been seconded by the invention of a wonderfully economical cement sluice by Mr. A. Murray, P. W. D., one of the specially satisfactory event of the year. A bad—that is too dry a season—in some districts and especially the failure of the North-east monsoon in the Eastern Province, make 1889 and part of this year a very unfortunate time for the rural population affected. We pay little attention here

to the unnatural, unhealthy agitation got up in a certain quarter—seldom happy but when agitating on a big scale—for a revolution in the system of grain taxation. The simple answer to such a demand is that the only alternative to the existing Ceylon system is the Indian system of land taxation, and that the Ceylon rice-cultivator as he is, is far more lightly taxed than his brother in India. In other respects, the condition of native agriculture is satisfactory and by degrees tea, cotton, tobacco and fibre-yielding plants may be expected to be added on a large scale to their gardens, while fruit and root cultivation is steadily extending. The holding of four Agri-Horticultural Shows—at Kandy, Matale, Kegalla and Matara,—is a matter for gratulation; for their influence for good on the people and their industries, is undoubted.

OUR NEW PRODUCTS.

(BY A PRACTICAL PLANTER.)

TOBACCO.

This product is no doubt making rapid strides in certain districts, and the coming season promises to add considerably to the acreage under cultivation; Wategama is to be the field of one Company's operations (Ceylon Tobacco Company, A. Philip, Esq., Secretary, with the Hon. T. North Christie as Director), where the soil and rainfall appear to be almost all that can be desired for this crop; land however in the district appears difficult to obtain. The tobacco grown at Wategama during this last season though somewhat small is of very fine texture and can be cured to the desired color to meet present tastes, at Wategama. With the above Company Messrs. Vollar and Gwatkin, T. C. Owen, Radley and others will be interested in tobacco cultivation. Matale, Katngastota, Kurunegala will also come to the front as tobacco-growing districts. The Ceylon Tea Plantations Company Limited propose opening tobacco clearings at or near Lunugalla. The curing of the tobacco in many cases will be done on the estates where it is grown, whilst other estates' tobaccos will be sent to Karandagalla to be cured by Messrs. Vollar and Gwatkin, who have, we understand, cured some 60 tons of their own and for other estates this season. The experience of several tobacco growers and curers from Sumatra, India and Borneo during their visit to Ceylon has been imparted to their friends here, during the past year which should assist in bringing this product to the English and Foreign markets as a more desirable article than it has previously been, and we shall look with interest to the future of tobacco as a paying investment for Ceylon planters.

COTTON.

Another product quite in its infancy when considered in connection with Ceylon, appears also to be attracting more attention by the European planters. Previously it has been almost entirely in native hands who have cultivated it in small quantities for their own use and found a difficulty in disposing of it for sale; now, however, with the Spinning and Weaving Company ready to purchase raw cotton in any quantity, there are prospects of cotton growing becoming a large agricultural enterprise in Ceylon.

Planters are evidently holding back for more reliable information than has yet been given on the subject of cotton planting. There is no doubt that cotton requires certain qualities in the soil to induce it to grow and bear well and the point will be to find what districts are suited to its remunerative growth; when this is known it might be planted with great advantage as a "catch" crop with say cacao, tea or coffee; being a six months' crop it would not interfere much with the growth of the young cacao, tea or coffee but would rather shelter these permanent products and provide the estate with funds by a quick return; two or even three crops might possibly be taken by pruning down the cotton trees after cropping before it would do any material damage to cacao. In Dumbara, Wategama and Matale we hear of very fine cotton being grow

between the young cacao; in one case it was planted between tobacco plants before the latter were cut down and now that the tobacco crop is reaped a very fine field of cotton reigneth in its stead.

The Spinning and Weaving Company should do all they can to encourage the growth of cotton by getting out a number of *cheap* hand gins for planters, whereby they (the S. & W. Co.) would receive the cotton ready ginned and save the planters immensely in transport. Cotton seed obtained with the cotton is in the proportion of at least 3 to 1, i. e. if cotton is sent to Colombo ginned, instead of paying transport on 4 tons it would only be on one ton; on unginned cotton of the seed is required on the estate again for planting or cattle feeding there is the return transport to be paid, so that there can be no doubt the S. & W. Co. can very materially encourage cotton growing by the above plan which will also bring the grist to their mills. By calling for tenders at home this Company would possibly be provided with suitable hand gins for a few £'s each, whereas now, the local prices given are R850 to R450!

We hear of some Ceylon-grown Sea Island Cotton selling in England at 1s 4d per lb. the highest price quoted by the Spinning and Weaving Company for Sea Island cotton is 40 cents per lb.; it is scarcely necessary to tell such business-like men as the directors of the Spinning and Weaving Co., that if they wish to secure Ceylon-grown cotton they will have to advance their rates to an equivalent to home prices. We shall a little later give the actual figures for cost of planting, supplying, keeping cotton free of insects (which are legion), picking, ginning, despatching to Colombo, &c., &c., with value received for the produce of a cotton clearing so that planters may judge for themselves what may be gained by growing this product.

TRADE IN CEYLON IN 1889.

(BY A MERCHANT.)

During the twelve months there has been a gradual improvement in trade generally and this must be traced mainly to the expansion of the Tea enterprise, large areas coming into bearing, more labourers being employed, more money circulating, and, as a consequence, an increased demand for imports and articles of consumption.

But other things besides tea have contributed to the welfare of the native community more especially in the steady demand there has been for the products of the Coconut tree, and for Cinnamon, Plumbago, &c. The total value of the trade of the island cannot yet be ascertained, but that it exceeds that of recent years there is no doubt.

The number of bushels of *Rice* imported at Colombo was 5,515,391.

In *Cotton Goods* the offtake has been on a larger scale, the heavier makes of shirtings having been most sought after, and business in gray dhoties has also been on the increase, whilst colored and printed goods have shared in the improvement. Imports of Manchester-made goods from India, and of Indian-made goods, have been on a considerable scale.

In *Metals and Hardware* there has been a marked increase to meet requirements created by the erection and extension of tea factories and estate buildings more especially, and there has been more general activity in the bazaars than for some years past.

In *Export* business has been on a full scale and in most cases at prices that have been fairly remunerative, as for the most part transactions now-a-days are on a 'cost and freight' basis and the old merchants' risk of consigning to markets, for realization on their account is pretty much a thing of the past.

Plumbago has been very largely exported, and during the past few months extremely high prices have prevailed. The advance was brought about through several vessels with cargoes for America having broken down on the way, thus causing a scarcity, which had to be satisfied. Since then arrivals have been more than sufficient, and prices are falling. The good prices that dealers have been getting have stimulated mining, and machinery for pumping is now being introduced at many of the pits.

Cinnamon has been depressed owing partly to accumulation of stocks but largely on account of the excessive exports of chips. This, however, will be rectified by the united action recently taken by growers, and there is a prospect of a good trade at the present level of prices.

Cinnamon oil and *citronella oil* have been in limited request until towards the latter part of the year, but great difficulty is experienced in procuring pure Essential Oils owing to the adulteration which has been so largely practised.

Coconut oil has fluctuated a good deal in price, but the export has been on an average scale. Latterly the prices of copra have advanced owing to the unfavourable season and limited yield of nuts, and the volume of transactions both in oil and the raw material has become curtailed.

Cotton has scarcely attained an important position yet, as regards quantity produced, but some very excellent descriptions are being grown, and the cultivation is certain to spread gradually.

It is not likely however at an early date to become an article of export (much as Manchester would like to have Ceylon-grown cotton), as there is a market at the new Cotton Mills at Wellewatta for all that can be raised. But if the island were opened up by railways, there is no reason why Ceylon should not become a large cotton-producing country like Tinnevely, the crop from which exported from Tuticorin during the last season has amounted to 120,000 carries of 500 lb. each and with the total value of R16,200,000.

Kapok (the fine but short-stapled fibre produced by cotton trees) meets with a ready sale, and the wonder is that it is not more largely cultivated, seeing that it commands from 20 to 25 cents a lb. cleaned.

Fibres.—The trade in Aloe fibre such as has been developed in Mauritius and Bahamas, has yet to be started in Ceylon; but 1890 ought to see a good beginning made.

1890 opens with prospects favourable to the island trade as a whole, but as rates of Exchange are tending upwards, the rupee values of produce can hardly fail to be weakened, whilst importers of goods would be benefited by any improvement in the value of the depreciated silver coin.

[We had hoped to get the value of the trade in 1889, but the Principal Collector of Customs cannot give it for some weeks yet.]

THE IMPORTANCE OF LIMING.

WITH PRACTICAL ILLUSTRATIONS.

By John Hughes, F.C.S., F.I.C., Consulting Chemist to the Ceylon Planters' Association.

The value of lime as an occasional dressing for the soil has been recognised from a very remote period. In this country, liming—that is to say, the practice of applying burned limestone—was usually associated with a summer fallow in preparation for wheat; but with the disappearance of this expensive mode of preparing a good seed-bed for the above-named cereal, the old custom of liming has also gone out of fashion. This is to be regretted for many reasons which may conveniently be arranged under the following headings:—

1. Lime is a necessary constituent of all naturally fertile soils, as it is required to make up the mineral portion of our crops.
2. On clay soils it has a wonderful effect in decomposing the insoluble silicates of potash and rendering them available as plant food.
3. On peaty land or rich vegetable soils it corrects the excessive acidity and promotes the formation of valuable nitric acid compounds from the previously inert nitrogenous organic matter.
4. On damp soils it improves the mechanical condition, making them not only drier but more friable and easier worked.
5. Finally, if used judiciously, lime may be truly regarded as the key for unlocking the hidden treasures of the soil, and making them available for the production of larger and better crops, while for certain diseases—such as fingers-and-toes in turnips—it is considered a specific in many localities.

In excessive quantities, or, if applied too frequently liming is, undoubtedly, exhausting, and this fact has given rise to the saying that lime is good for the father but bad for the son.

Liming should be followed by manuring, and then the full benefit of both will be obtained. Indeed, without a sufficient supply of lime in the soil, the application of ordinary farmyard manure is frequently most disappointing in its results, especially in the case of root crops.

Before proceeding further, however, it will be useful to mention in a tabulated form the relative amount of lime removed from the soil by the ordinary farm crops, and the reader will easily understand by looking at the figures which crops remove the most, and therefore, should not be sown unless the land contains a sufficient supply of lime, or it is proposed to add it specially.

Lime removed per acre by an average crop of the following:—

		lb.	lb.
Clover hay	2 tons,	contain	86
Turnips	root 17 tons	" 25	} = 74
"	leaf	" 49	
Mangels	root, 22 tons	" 24	} = 53
"	leaf	" 29	
Swedes root, 14 tons	" 20	} = 42
"	leaf	" 22	
Beans	grain, 35 bush	" 3	} = 33
"	straw	" 30	
Meadow hay	1½ tons,	"	28
Potatoes	tuber, 6 tons	" 3	} = 26
"	haulm	" 23	
Oats	grain, 45 bush... ..	" 2	} = 12
"	straw	" 10	
Wheat	grain, 30 bush... ..	" 1	} = 11
"	straw	" 10	
Barley	grain, 40 bush... ..	" 1½	} = 10
"	straw	" 8½	

From the above it will be seen that corn crops require but little lime, and that most of it exists in the straw, which we know is usually returned to the land in the form of dung.

Potatoes, meadow hay, and beans come next in the table, then swedes, mangels, and turnips, and, finally clover hay, which, in a moderate crop of 2 tons, removes as much as 86 lb. of lime per acre. In addition to the crops mentioned above, peas, vetches, and sanfoin also require a generous supply of lime in order to yield good returns.

We find upon inquiry that the use of lime seems to be limited to certain localities, and that the quantity applied per acre, as well as the quality of the lime, varies in different parts of the country.

Thus, in Scotland, in the western counties of England, and in South Wales the practice of liming is still much esteemed by practical farmers, while in the southern and eastern counties, where the soil is naturally calcareous, being connected with the upper and lower chalk formations, and where the climate is warmer and the rainfall less, it is not usual to apply me in its caustic condition; though in counties such

as Lincolnshire and Yorkshire much benefit is derived from a good dressing of chalk marl every nineteen or twenty years.

Again, in Cornwall sea-sand, rich in carbonate of lime, in the form of minute particles of marine shells is extensively used for mixing with farmyard dung as a manure for barley.

Indeed, this local practice of applying lime in the milder form of carbonate teaches us that on light sandy soils, naturally poor in organic vegetable matter, it is more prudent to use lime in this condition than in the caustic form of calcined limestone, which would have an injurious effect on such light soils.

Moreover, we may fairly conclude that if finely-ground shells are useful as a dressing for soils light in character and deficient in lime, finely-ground raw phosphates, such as coprolites, Belgian phosphate, or the more recently introduced basic slag are also suitable and economically valuable fertilisers, although the phosphate of lime is in the form known as insoluble phosphate.

In the next place, as regards the quantity of lime applied, there is great variation. Thus, in Scotland, notably in the neighbourhood of Roxburgh, as much as 200 bushels are used per imperial acre, at intervals of every nineteen years, whereas, near Durham, 90 bushels every twelve years, is the usual dose, and on the red soils of Worcester, 70 every six or eight years.

The weight per bushel varies from 70 to 100 lb., according to the quality of the lime and the care taken in burning. As a general rule, it may be taken that the quality varies with the weight; the less the weight the better the quality.

There are a great many varieties of limestone which, on burning, produce a corresponding variety in the quality of the lime.

In Somersetshire and Devonshire there is the famous carboniferous or mountain limestone, in Glamorgan-shire the well-known lias limestone as found at Aberthaw. In Pembroke-shire we find silurian, also caradoc, which latter although, containing 80 per cent. of carbonate of lime, is regarded by geologists as a sandstone on account of its gritty formation.

Lastly, the coelitic lime tones of Gloucestershire and chalks of Kent and Sussex form another class which yields a great variety of caustic lime.

Speaking generally, the best limestone for agricultural purposes is that which yields after burning the purest and white-t powder on slaking with water.

Mountain limestone produces excellent lime; 1 ton should yield, after burning, 11 cwt. of caustic or quicklime.

The goodness or richness of lime may also be noted by observing the quantity of water absorbed during slaking—the more, the better the quality. The superior limes swell out and increase in bulk from two to three times their original size. When a farmer, therefore, has the choice of different qualities, it will be worth his while to get some information as to which it will be most economical to employ.

Freshly-burnt lime is soluble to the extent of 1 part in 770 parts of water, and has a hot, alkaline taste, which is very marked when compared with the mild taste of powdered chalk, which is only soluble to the extent of 1 part in 3,500 parts of water, or 2 grains per gallon.

Lime has a natural tendency to work downwards in the soil as it becomes dissolved; it should, therefore, never be ploughed in, but sown broadcast on the surface, and the land allowed to remain untouched for a week or so.

In the analyses of the drainage water from the experimental plots at Rothamsted, it was found that the quantity of lime passed through the soil increased with the quantity of nitric acid passing away.

Thus, while the water from the unmanured plot contained only 6.97 grains of lime and 1.05 grains of nitric acid per gallon, the water from the plot manured with a heavy dressing of sulphate of ammonia contained 13.81 grains of lime and 4.55 grains of nitric acid per gallon.

Similar results were noticed where nitrate of soda was applied, as also, though not to the same extent, in the plot where ordinary dung was used. We may infer from this that nitrogen, when resolved into nitric acid, combines with lime as its favourite base, so that it is most necessary that soils should contain a sufficient supply of this important constituent whenever nitrate of soda, sulphate of ammonia, or even farmyard dung is intended to be applied.

It may here be mentioned that all soils which contain less than 1 per cent. of lime in the form of carbonate of lime may be considered as deficient in this respect, while those containing more than 4 per cent. of carbonate of lime should not, as a rule, require any additional supply.

It is a curious and interesting fact that of the soils sent up from different parts of the country for analysis and report from time to time, in most of the cases there is a very marked deficiency of lime, and it may be useful to conclude this paper by introducing a few of the results as practical illustrations of the importance of liming.

No. 1.—Soil sent by Mr. John Mountain, Braceborough, Lincolnshire, and taken from a field of turnips which were affected so badly with fingers-and-toes and canker at the roots that there was not a sound bulb in the whole field.

On analysis of the dried soil only .38 per cent of lime was found—in round numbers $\frac{1}{2}$ grain in 100 grains. This failure of turnips was no doubt due to insufficient lime and acidity of soil, as there had been 10 tons of dung and 3 cwt. superphosphate applied per acre, which should have given a good crop.

No. 2.—Soil from Llanhilleth Rectory, Monmouthshire, upon which it was found impossible to get a crop of peas though well-dressed every year with horse manure. On analysis only .12 per cent of lime was found. The application of a good dressing of freshly-slaked lime in the autumn produced a marked effect the following summer, as an excellent yield of peas was obtained.

No. 3.—Soil sent by Mr. J. Sutton, Abbey Farm, Huntingdon, and taken from a field which only gave 2 qrs. of barley per acre, notwithstanding that 4 cwt. of good artificial manure had been applied.

Found the soil to be unusually acid, with much vegetable matter containing .34 per cent of nitrogen and only .79 of lime.

The land evidently wanted draining and liming, and this was recommended accordingly.

No. 4.—Soil, from Mr. John Norman, Barton Farm, Horwood, Devon, and taken from a field of a light, porous nature, upon which seeds following oats had failed in 1884.

On analysis only .40 per cent of lime was found, or less than $\frac{1}{2}$ grain in every 100 grains, and it was therefore no wonder that clover seed had failed.

It would be possible to give a greater number of instances where lime was found to be deficient, but space will not admit. We should remember that the use of manufactured manures, such as super-phosphate dissolved bones, or even dissolved Peruvian guano, does not render the occasional application of lime unnecessary. Indeed, quite the contrary, as all these manures are essentially acid in their properties, and doubtless tend to make the soils upon which they are used more acid than they otherwise would have become under the old-fashioned way of farming.

Moderate but more frequent doses of lime are therefore required to counteract this tendency to acidity, as well as to meet the direct requirements of plant life. Lastly, in districts where limestone is used for metal on the roads, the muddy scrapings will furnish one of the most economical dressings for the improvement of the adjoining grass meadows.

79, Mark Lane, E. O.

CINCHONA IN JAVA.

Our Amsterdam correspondent writes:—"It is a fact deserving attention that in 1889 about 44 per cent more Java cinchona bark of private plantations has been sold here than in the preceding year, viz. 3,719,965 lb., whilst I had in my letter dated December

28th, 1887 estimated the importation of private bark in 1889 at 25,000 packages of about 150 lb. each equal to about 3,750,000 lb. A London firm of brokers are apparently in error in saying, as they do in a recent report that 'the present crop of Java cinchona bark shows a moderate increase as compared with the previous (1887-88) Java crop'; and also in their statement in an earlier report, that 'the last crop (1887-88) of Java bark shows an increase, but not the heavy quantity anticipated by so many expressing an opinion.' The firm in question probably alluded to your issue of 31st December 1887, in which the future output of Java crop (1888 and 1889) was correctly estimated, as I do not know of anyone else having published an opinion with figures on this subject. I maintain my opinion expressed in my letters of December 14th and 28th, 1887:—(1) That an average of 4 per cent of quinine (sulphate) in the bark produced is the vital question for a plantation of cinchona bark; (2) that Java, where still many poor trees, cultivated from seed are existing, will progress in quantity and quality of its bark from year to year; and (3) that Java and other districts producing bark of at least 4 per cent quinine will in a few years be the only ones where cinchona growing will offer a profit, however moderate that may be."—*Chemist and Druggist.*

THE ORIENTAL COFFEE COMPANY, LIMITED.

Mr. J. Young presided over the thirteenth annual general meeting of the shareholders of the above company, held recently at the offices, 32, Great St. Helens, E. C., and moved the adoption of the report, in which the directors pointed out that the result of the year's working, although fairly good, was not so satisfactory as was expected, owing entirely to unfavourable weather. A heavy monsoon was followed by a long drought, which prevented a good deal of crop from ripening, and the total quantity shipped was 83 tons 2 cwt. The prices obtained for coffee fortunately compensated, in a great measure, for the deficiency in the estimated crop, the average realised having been 86s. 9d. per cwt., against 65s. 5d. the previous year. The balance sheet showed that, after covering the adverse balance brought forward from last year, and the payment of an interim dividend at the rate of 5 per cent. per annum, a sufficient amount remained to pay another dividend at the same rate, and carry forward £313 11s 2d to the current year. This, it was hoped, would be satisfactory to the shareholders under the circumstances. The prospects for the coming year were not so good as was hoped for, the drought above-mentioned having lasted just long enough to injure the blossom considerably, and having been followed by an equally long period of heavy rain with hardly any of the usual breaks of sunshine, the growing crop had inevitably suffered, and would probably not exceed eighty tons. But as the price of coffee had advanced, and fine qualities were likely to be scarce, the directors trusted that the result of the year would be about the same as the last. The speculative excitement of the year having centred mainly on mining and breweries, the directors had not considered the time opportune to endeavour to make a further issue of shares in a purely agricultural enterprise, but would carry out the wishes of the shareholders as soon as a favourable time arrived. The report was adopted.—*H. & C. Mail.*

COFFEE IN BRAZIL.—"The Instituto Fluminense de Agricultura, Government experimental farm, has succeeded in grafting Maragogipe and Java coffee"—says the *Rio News*—"on Liberian stocks. This is an important matter, if it can be made of commercial value, for the state of Rio de Janeiro particularly, for if the old stocks can be used for grafting, and this can be done with some fruit bearing trees, there is no reason why this coffee zone should not show a return of its former prosperity."

TEA.

(From Messrs. I. A. Rucker & Bencraft's Weekly Tea Circular.)

LONDON, Dec. 19th, 1889.

TWELVE MONTHS' PUBLIC AUCTIONS.

Public Sales of Tea from January 4th to December 19th, 1889.

Ceylon averages and monthly deliveries.—a January: Deliveries 1,946,832, average about 10½d. b February: Deliveries 1,915,114, average about 10½d. c March: Deliveries 2,137,838, average about 10½d. d April: Deliveries 2,105,018,

average about 9½d, Whitsun Holidays. e May: Deliveries 2,893,198, average about 9½d. f June: Deliveries 2,667,890 average about 9d. g July: Deliveries 3,677,728, average about 11d. h August: Deliveries 3,200,918, average about 1s 0½d, great strike. i September: Deliveries 2,900,718, average about 1s 1½d. j October: Deliveries 2,635,483, average about 1s 1½d. k November: Deliveries 2,177,092, average about 11½d. l December: Nil.

CEYLON TEA.—We have experienced a firm market for all teas below 1s, but regret to say finest pekoes and broken pekoes have had to be almost sacrificed to effect sales. We anticipate that when quality falls fine teas will go higher, but unfortunately the keeping qualities of Ceylon tea have so often proved wanting that few will venture to hold their teas for a rise. The figures for the public auctions for twelve months, which are printed on the other side, will prove very interesting if compared with our circular of same date 1888. The same feature to which we called attention then is very marked now, namely the effect of low prices in assisting and stimulating deliveries. After five months of low cost in March, April, May, June and July, the deliveries for five months were 15,340,502 lb. The deliveries of seven months of higher prices being 12,938,430 lb. Cheap teas were taken to the extent of 3,667,890 lb. in June, and fell to 2,177,092 lb. of high cost tea in November.

SUGAR AND VANILLA IN MAURITIUS.

Port Louis, Dec. 11th, 1889.

SUGAR.—The Weather and the Crop:—The season has been a remarkable fine one for crushing operations so that it is probable that the coupe will be entirely at an end before the end of December. The young plants are beginning to suffer in some districts from the want of rain, but the evil will soon be repaired, for we are now entering upon that period of the year when the whole Island is abundantly watered owing to the vicinity of passing cyclones. The yield has on the whole not been quite so satisfactory as we had hoped, and this is to be attributed to scarcity of rain during the months of April and May this year; it is therefore to be expected that the total of this year's produce will be inferior to that of last year.

THE SUGAR MARKET.—The market has shown great animation throughout the month and several important sales have been made for our various export-markets, excepting for Europe, where ruling prices are considerably below other quotations. In the face of a diminished harvest and of a stock on hand which is inferior to that of last year and of the small quantity of sugar in first hands, holders are very firm at this day.

We are in advance in our shipments as compared with last year to the extent of 7,758 tons, and with those of the previous one to the extent of 9,378 tons.

VANILLA.—The market is firm—we have to record the sale of a few lots fine quality at R26.25 per kilo above 6 inches. Vanillos from R10 to R12 per kilo. As we mentioned in our last, the outturn of the present crop will not exceed 12,000 to 13,000 kilos.—Merchants and Planters Gazette.

WEATHER AND PLANTING IN MADULSIMA.

CAPITAL PRICE FOR MADULSIMA TEA,

Madulsima, Jan. 7th.—The weather has been splendid since the 31st Dec. for drying and dispatching quantities of bark, but very rough on tea clearings and supplies. I don't remember a worse planting monsoon; and I don't think work had to be stopped more than once on account of the rain, during the whole monsoon. Rainfall for 1889 110.19 inches, against an average for previous 5 years of 126.06 inches. Some large additions are to be made to the acreage of tea on several estates, during this year: I hear of one estate putting in over 200 acres, and another 150 acres. I don't think you noticed the fine price obtained for the tea from a small estate at the far end of our district, I saw the last lot of broken pekoe fetched 1s 7d.* on a poor market; the only other estate to equal this was Culloden, and none was superior. Very creditable to all concerned. Best wishes for 1890.

COFFEE IN CENTRAL AMERICA AND BRAZIL.—Late advices from the interior of the province of Ceará give very good reports as to the prospects for the coming coffee crop. The trees are very healthy and strong and a heavy bloom is expected.—It is said that notwithstanding a probable loss of 10,000,000 lb. for want of labour to save the harvest, the exports of coffee from Guatemala during the present year will show a considerable gain over 1888. Great attention is being given to the cultivation of the berry, and it is estimated that within a year or two the product will reach 100,000,000 lb. The country itself consumes about 10,000,000 lb.—*N. Y. Com. Bulletin*, in *Rio News*.

THE SALE OF TEA BY CHEMISTS.—The *Grocer* has an editorial in quite a Jiugo strain in respect of our innocent article in the *Diary* on "The Tea Trade." (See page 493). It is described as "an ambitious attempt to instruct chemists how they may not only sell bleached teas, but also blend for themselves." It appears that grocers "devote years of hard work" to the study of this art (or is it a science?) of blending teas, "and find, even then, that their knowledge comes none too easily." We really did not know that our grocerial friends were such a dull lot—"Years of hard work" to learn how to mix equal parts of Assam Pekoe and Ceylon Pekoe, and scarcely get to understand the business when the severe strain of the study has made their heads bald! And now chemists and druggists can learn all about it in half an hour. It is indeed a revelation. And what a testimonial, too, to the quality of our *Diary*! For the "organ of the trade" has evidently been through the article with Sam Weller's double-million-power magnifying-glass, and does not record the discovery of the shade of an error. And then the gentle *Grocer* man—who must be a new hand—proceeds to advise his readers to restore the balance by selling patent medicines. His own paper has been giving more or less accurate advice on that subject for years; and now he has discovered the opening. Verily it does take a mind, as Hosea Biglow says, "as big as all out-doors. To make out it looks like raining. After once it fairly pours."

UNEQUALLED TEA FOR THE CZAR: SIX HUNDRED MILES UP THE YANG-TSE-KIANG.—The Yang-tse-kiang, the third largest river in the world, and more than three thousand miles long in all its windings, from its rise in the north-western mountains of China to its discharge into the Yellow Sea, is navigable by steamboat as far as Jehang—a thousand miles up from Shanghai. There are three companies which run steamers up the river, and it was in one belonging to the China Navigation Company, the "Nganking," a fine vessel of 3,000 tons, fitted up with every latest improvement, that we recently made the journey, to and fro, from Shanghai to Hankow. The distance is six hundred miles, and the trip there and back, which occupied nine days, proved in every way interesting and enjoyable. Large numbers of "Chasus" go up every May to the river ports, and even as early as April we had quite a crowd of them in the "Nganking." We had learned to look upon the "chasu" with mingled fear and dread, for every one kept saying, *apropos* of our trip, "Better go early and so avoid the 'Chasus'"—it was a great relief to our mind, therefore, to discover him, later on, to be neither more nor less than a simple tea-taster. Our "Chasus" were all Russians, and bound for Hankow, which is one of the largest marts on the river for the tea-trade. At the house of the hospitable Commissioner of Customs we tasted some tea which I should imagine for delicacy of flavour must be unequalled; it was some that he had received as a gift from a "chop" sent to the Emperor of Russia, and is not to be bought for money, being reserved exclusively for the use of the Imperial Court.—*Graphic*, Dec. 7th.

INSECT IN COFFEE: GONAMOTAWA, HAPUTALE, Jan. 4th.—I enclose you an insect, caught on a coffee tree recovering from an attack of green bug—which species it closely resembles. Can you classify it?—*Cor.* [Our entomological referee, reports:—"The green insect is the larva of a small cicada, allied to the frog hopper. They can do no harm to Coffee."—*Ed.*]

THE ASAHAN TOBACCO COMPANY has been established in this city (Amsterdam) with a capital of 1,000,000 guilders in two series each of 500,000 guilders, the first of which has been fully taken up. The object of the company is to work and cultivate grounds near the east coast of Sumatra. Tobacco, as well as other produce, will be cultivated.—*Cor., L. and C. Express*, Dec. 27th.

THE FIRST 1890 CINCHONA AUCTIONS.—At Tuesday's bark sales it was agreed unanimously, upon the motion of Mr. David Howard, seconded by Mr. D. B. Tabor (W. H. Cole & Co.), to fix Tuesday, January 14, 1890, as the day upon which the first bark sales of the coming year shall be held. The last auctions of the present year will take place on December 17th.—*Chemist and Druggist*.

A LIMITED TEA Co.—Under the title of W. H. and F. J. Horniman & Co., Limited, the business of the well-known tea dealers and packet tea proprietors has been converted to the joint stock form. The capital of the Company is £250,000 in 4,000 preference shares of £25 and 3,000 ordinary shares of £50 each. The subscribers who take one share each are: F. J. Horniman, 29 to 33, Wormwood Street, E. C.; W. Figg, 33, Mincing Lane, E. C.; G. W. Potter, m. d., 8, King Street, Oneapside; J. W. Jones, Sussex House, Hornsey Rise; J. T. Livermore, 36, Fairholt Road, N; F. H. Stollery, Norfolk House, Clapton; A. Scarr, 55, Varley Road, N. There shall not be less than three nor more than seven directors. The first are F. J. Horniman, E. J. Horniman, J. R. Manning, and L. R. S. Walcott. Qualification, £2,000. F. J. Horniman is appointed chairman with a remuneration of £1,000; other directors to receive £250 each.—*H. & C. Mail*.

A New Coccus.—At the meeting of the Scientific Committee of the Royal Horticultural Society on December 10th, Mr. Morris read a letter addressed to the Director, Royal Gardens, Kew, by Mr. R. W. Bluffield:—"I see in the August number of the *Kew Bulletin*, an interesting account of the *Cerya purchasi*, and its depredations in South Africa, California, &c. During the past four years our gardens at Alexandria have been invaded by a coccus, which threatens now to destroy all our trees, and is causing the greatest alarm here. . . . It first appeared about four years ago, when I noticed it in quantities on the under side of the leaves of a banyan tree, but it has since spread with extraordinary rapidity, and one of our most beautiful gardens, full of tropical trees and shrubs, has been almost destroyed. A breeze sends the cottony bugs down in showers in all directions. It seems to attack almost any plant, but the leaves of the *Ficus rubiginosa*, and one or two other kinds of fig, seem too tough for it, and it will not touch them. It seems almost hopeless here for a few horticulturists to try to eradicate this formidable pest, while their indifferent neighbours are harbouring hotbeds of it, and there will have to be some strong measures taken by law to put it down." The insect in question had been referred to Mr. Douglas, and was said to be an undescribed species of *Dactylopius*. Spraying with kerosene emulsion was recommended, but no remedy was likely to be effectual that was not carried out universally.—*Nature*, Dec. 26th.

“THE GEMMING AND MINING CO. OF
CEYLON, LIMITED.”

This mail brings us a copy of the prospectus of the first registered Ceylon Gemming Company, and a very long and interesting document it proves to be. The Company also forms the subject of a good deal of information in our London Letter including a reference in the City article of *The Times* from the Secretary of one of the rival “Gemming and Mining Syndicates” which, to say the least, is not very generous, although from the similarity of names it may have been thought necessary to prevent mistakes in identity. No doubt the Syndicate which has sent out Mr. Barrington Brown—known popularly in Ceylon as Messrs. Saunders and Harding’s Company—deserve credit with British capitalists for taking the prudent step of having a professional expert’s opinion before trying to launch a Company. This is the course also followed by the second Syndicate promoted by Mr. Davis of Messrs. Gow, Wilson & Stanton, whose agent Mr. Fahey has just arrived in the island. At the same time, we were bound to say in defence of the course adopted by gentlemen so much local standing and experience as Messrs. Geo. Vane, C.M.G., Thos. Dickson and E. T. Delmege—who, with Mr. P. E. Linthilac (Messrs. Dufour Bros. & Co., Director Gold Trust and Investment Co.) and Mr. Charles Schmalz (Messrs. C. Schmalz & Co., Diamond Merchants Paris) form the Directorate of the Company whose title heads these remarks,—that they have a thoroughly good answer to the implied criticism of Mr. G. T. Verney in the *London Times*. Their prospectus shews this, in pointing out that they require no expert’s report as to gems being found in the principal properties they have secured. The gems, gemmers and gempits are all there; the work is even now being prosecuted—the business this first Company takes up, is in fact “a going concern” only requiring proper, practical management and scientific appliances in machinery &c. to develop an industry on the scale justified by the capital now to be expended. That capital moreover is of a more moderate amount (£100,000) than the sum (over £300,000) projected in connection with the first Syndicate, and we believe that the Directors and their friends are prepared to take the entire responsibility even if the general public do not care to secure any part of the shares offered. Indeed this news is confirmed by a card from one of the Directors written just as the London mail closed on the 20th ultimo and stating that at a meeting of the Board then sitting, “they had decided to go to allotment.” Another fact in favour of this Company is that they have secured local Directors in Messrs. C. E. H. Symons, Jacob de Mel and S. C. Obeyesekere with Messrs. Delmege & Co. as local Agents and the New O. B. C. as Bankers. But the main point in their favour is their acquiring outright the Everton and Aberfoyle estates—the price paid being over £11,000 sterling—and mining rights over Rangwelltenne, Springwood and Barra estates. While Everton has been a mine of wealth to gemmers for years, the other properties are reported to have valuable gem lands and some plumbago deposits. Along with the prospectus the Company have issued a rough sketch map showing the position of all these properties, the distances to Colombo, &c. On the back of this, there is a whole page devoted to extracts from the *Ceylon Observer*, and our book on “Gold, Gems and Pearls in Ceylon and Southern India” is specially quoted in the prospectus. Should success therefore attend this Company and others to follow which have been indebted for information to the same

source, a percentage of the profits should be set aside for the compilers! But to resume, the arrangement made in acquiring mining rights over the estates named strikes us as an eminently equitable one—indeed a very favourable one to the proprietors. They are to be paid first of all R1 per acre per annum over the whole extent for five years; 2ndly, compensation by valuation for any damage to planted land in opening pits; 3rdly, an expenditure of at least £500 sterling on each property in prospecting is guaranteed; and 4thly, the proprietors are to have 20 per cent (1-5th) of the actual profits from gems found on these estates. Nothing could be fairer to estate owners than such terms, although it would almost appear a better bargain for Mining Companies to buy estates outright at the current rates of value for tea-bearing fields.

Since writing the above, we learn from the local Agents—whose advertisement will shortly confirm the news—that the capital of the first Company registered had all been subscribed before the mail left in the proportion of one-fourth by the public and three-fourths by the wealthy Companies behind the promoters that from the first undertook to float the concern on the information placed before them. It is certainly a curious fact that nearly all the richest of our Sinhalese are known to have made much of their money out of plumbago, the Messrs. de Mel, Fernandos, Paulis Silva, &c.—In the *Financial News* of December 17th, we find the prospectus of the Company headed with the following curt notice:—“The subscription will open on Thursday the 19th instant and close on or before Friday, December 20th.” Not much time allowed for the public to subscribe! From the editorial columns of the same paper referred to we take the following:—

Ceylon, which has from time immemorial been famed for its gems—sapphires, rubies, oriental topaz, garnets, amethysts, cinnamon stone and catseyes—has at last attracted the attention of the company promoter, and it is announced that a company has now been formed to carry on the gemming industry in a systematic manner, on a large scale and with the aid of the best of machinery and of engineering skill. Mining for precious stones has long been a paying business among the Sinhalese, who have carried it on in the primitive manner, with very imperfect appliances; and it is believed that, with the advantages that the new company will enjoy, the industry may be developed into one of great importance and profit. Gemming is, of course, one of the most speculative forms of mining, but it is one which, when it does pay, pays handsomely.

We now quote rather freely from the prospectus itself—this being the pioneer of, we trust, a good many similar Ceylon Mining and Gemming Companies:—

GEMMING AND MINING COMPANY OF CEYLON, LIMITED.
—Incorporated under the Companies acts, 1862 to 1888. Capital £100,000, Divided into 49,950 Ordinary Shares of £2 each, and 50 Founders’ Shares of £2 each.

A special feature of this undertaking is that some well-known Ceylon gentlemen have allowed their names to be identified with the enterprise, and have consented to give the benefit of their experience to this company, and will be upon the spot to overlook the working and management of the gemming industry. Messrs. Delmege, Keid & Co., of Colombo and Galle, who are interested in some of the undermentioned properties, have expressed their willingness to act as local agents, and the London Board consider this a guarantee to the shareholders that the anticipations contained in this prospectus will be fully realised.

This Company has been formed for the purpose of acquiring the freeholds (subject to a small Government license) of the well-known Estates of Everton (native name, Kabragallakelle) and Aberfoyle (native name, Kalkanda), being a portion of some of the richest

gemming land situated in the Rakwana district Ceylon; and to provide capital for developing the properties and working the gemming pits already sunk and proven.

The properties, which have been known for many years past to dealers in precious stones, consist of:—

Everton	about 760 acres
and Aberfoyle	" 520 "

Together... " 1,280 "

being situated within 2 miles of Rakwana, and in the immediate vicinity of the Botiyatenna Estate, whose owner is reputed to have made a fortune by gemming it.

Mr. Thomas Dickson has further negotiated for the acquisition of the mining rights of the following properties for a term of five years, with the option of renewing same every five years upon payment of a nominal rent of one rupee per acre yearly, and a Royalty of 20 per cent of the net profits realised by gemming and mining upon each Estate separately, and the same will be included in the intended sale to the Company:—viz.,

1. Rangweltenne estate, consisting of 404 acres of land, forming the northern boundary of the Everton estate. Valuable gems have been found upon it, and the indications of what would be discovered by systematic working are very good. As much as R60 per month have been offered and refused for a license to open a pit with a few feet of area. 2. Springwood and Barra estate, consisting of about 1,100 acres. Precious stones have been found on this estate, part of which forms the east boundary of Aberfoyle estate. On the alluvial land on Barra estate the "Illan" indications are good, and precious stones have been found in it, but as yet no licenses have been granted for gemming. The cart road passes through the estate. Valuable deposits of plumbago, of which Ceylon has practically the monopoly, have been discovered on this property, and the veins are now being worked.

The above and the following particulars regarding the Estates have been furnished by Mr. C. E. H. Symons, who for many years past has taken a great interest in the search for precious stones as carried on by the natives, and whose practical knowledge has been placed at the service of the Company, and from information supplied by Mr. Charles Shand, of Colombo, and Mr. A. A. Delmege, of Messrs. Delmege, Reid & Co., who have visited some of the Estates to obtain authentic information as to the value of the land for gemming purposes.

Mr. Symons reports, under date September 12th, 1889:—The tract of land comprised in the accompanying sketch contains some of the richest gemming fields in Ceylon—the Everton Estate, known to natives as Kabragallakelle, runs from 2,810 to 3,300 feet in elevation. This Estate has been famous for its gems for the last 30 or 40 years; the purity and depth of colour of the Sapphires found on the Estate are proverbial. Catseyes of the highest value have also been found in quantity, but only a very limited area has been gemmed—some 10 or 12 acres at the outside—and that only in the most primitive fashion. The stones found so far on Everton are Sapphires, Rubies to a limited extent, Catseyes, Tourmaline, Amethyst, Topaz, Common and Star stones. Corundum could be found by the ton, and there are several promising veins of Plumbago, want of capital being the reason the mineral have not been worked. Crystals of remarkable size and purity of whiteness are found in quantity, and for optical purposes they are unsurpassed.

There have been from 50 to 60 pits sunk in Kabragallakelle, (Everton) which exist to this day, the most of them only sunk to the first strata of ilium, a few having been sunk to the second strata. He further states with reference to Aberfoyle: Gemming has never been systematically carried on here to any extent, but pits here and there have been sunk with success, and the anxiety of natives at the present moment to get licenses to dig, shows that the few are doing well; indeed, it is positively known that one man has during the past week found sapphires and rubies valued at over R2,000, and his pit is not 10 feet below the surface. The estate is peculiarly

situated, having precipices on three sides of it, so that none of the stones that were washed into it in ages past can have found their way out, being stopped by the precipices that surround it, and the best judges have declared the land to be, and the most promising gem land in the district.

Mr. A. A. Delmege in writing, states:—The land you have got is unique; gems, and valuable gems, have been coming out of it for years, and you see the papers certify to the fact that gems are now coming out of the land. This is the gem land of Ceylon. The land is the most notorious for authentic finds. The finds have extended over a long series of years, and the quality and value of the gems found are known to be of great value; for instance, page 72 in Messrs. A. M. and J. Ferguson's book upon "Gold, Gems and Pearls in Ceylon and Southern India," states that £9,000 worth (of gems) were taken from the Everton Ridge and Batakanda from $\frac{1}{2}$ acres, and R90,000 worth of gems were sold at one auction being found near Martinstown. On page 110 of the same book:—"7,000 worth of gems have been picked up on one Rakwana estate in a year (the writer no doubt referring to Everton.)"

It is known in Ceylon that gems—that is, Sapphires, Catseyes, Rubies, and, I believe, Alexandrites, and numerous gems of lesser value—have been for many years steadily found on the land represented on this map. So far as I am aware there is no other such pieces of gemming land in Ceylon. Gems for years have been and are steadily found on it. Their value must aggregate many thousands of pounds, but there are no means of ascertaining their value, as the natives keep all finds a profound secret, and take the stones to Ratnapura, 28 miles distant, where Moorish dealers go constantly to buy them. Yet you may say the ground has scarcely been scratched. Doubtless there must be gems to an enormous extent to be got only wanting European capital and enterprise to bring them to the light of day.

Samples have been received which are on view at the Company's office of Sapphires found in the Rakwana district, and upon the Estates acquired by this Company. On page 71 of the book previously quoted it is stated: "We have seen Mr. Dixon on his return from the Rakwana district. Gem pits exist on Everton Estate to the depth of 40 yards, and Mr. Dixon saw finer stones (Sapphires chiefly) than any he had previously seen in the Island. Two or three were valued by the Chetty owners at over £200 apiece. The gravel pits are easily worked, very little machinery being required. Labour is abundant, and can be obtained at nearly nominal rates. Planters accustomed to work natives are easily got at a small remuneration. A good bridle-road runs through the Estates to Rakwana, a distance of two miles; and here it meets with the Government cart-road to Colombo. There is more than ample timber on the Estates for all purposes, and water for washing is to be had in abundance, as may be seen from the plan."

The Directors, having every confidence in the high character of the gentlemen who have reported on the properties, as also in the information contained in Messrs. A. M. and J. Ferguson's book, which is fully confirmed by the articles which have appeared in the leading Ceylon newspapers of recent dates, a few of which accompany this prospectus, have no hesitation in expressing their favourable opinion of this undertaking. As this will be the first Company in the East, with the exception of the Burma Ruby Mines, that has been started with the view of prosecuting the gemming industry in a practical and business-like manner, with the assistance of the best class of machinery and European engineers, the Board cannot make a fair estimate of the probable profits, but they see no reason to doubt the success of the operations of the present Company, and a very substantial return to the Shareholders in the near future. As the property is of such large extent the Directors may consider it advisable to dispose of part of their Estates to other Companies. An offer has already been received of £250 per annum as a rental for a small portion of the Aberfoyle Estate for tea planting. Should this

offer be accepted, the Directors will be careful to retain in their own hands all mining rights. The Directors have provided that out of the present issue £20,000 shall be appropriated as working capital, which should be ample; but to provide against contingencies 15,000 shares (say £30,000) will be held in reserve for issue if required, for further working capital or other purposes of the Company. Messrs. Loos and Van Cuylenburg, one of the leading firms of solicitors in Colombo, will certify that the title deeds and leases are all in order, and no part of the purchase money will be paid to the vendors until the properties are transferred to the Company with a good title free from incumbrances.

The vendors, who are the promoters of the Company, will sell the proprietors and leases, and undertake to pay and indemnify the Company against all expenses of the establishment and promotion of the Company (except brokerage and the fees payable to the Government upon the transfer of the property to the Company) for £50,000 (payable as to £11,500 in cash, and £38,500 in fully paid up ordinary shares or in cash, or partly in cash and partly in such shares, at the option of the Directors) and the right to the allotment of the Founders' shares at par, under the terms of the undermentioned contract of December 5th, 1889, and thereout the vendors will satisfy all their engagements. This will leave a working capital of £50,000 as above mentioned.

GEMMING IN RAKWANA.

January 6th.

Messrs. W. Saunders and Barrington Brown have been in the district some days. They are staying at the Resthouse, and for the present have been visiting gemlands and making diverse enquiries. The Hon'ble Mr. Saunders, C. M. G., had accompanied his brother but left after a short stay, a special coach conveying him to Ratnapura. There was a great sale of gem on Botiatenne on Saturday last. The proceeds were over R2,000 for the gems from one pit, and over R900 for the gems from another. The lucky proprietor who gets his 1-5th from all sales must be congratulated. The Botiatenne pits have always paid well, and the proceeds of the various sales must have by now exceeded R40,000 on the spot. The pit owners would have to deduct expenses and interest on capital sunk, before making any profit out of the gems sold, but the owner of the land gets 1-5th without much expense, save that of a couple of representatives to watch proceedings and guard against thefts as well as illicit gemming.—Local "Examiner."

THE PRIESTMAN OIL ENGINE.

A correspondent calls our attention to the following notice of this engine in the *Electrician* of Dec. 20th.

Since its first introduction, some few years ago, the Priestman engine has been considerably improved, and as a consequence, it is now steadily making its way. The uses to which a reliable portable engine, requiring little attention and few repairs can be put, are so numerous that it is not surprising to find an engine like the Priestman which fulfils these requirements to so large a degree, should be in great demand. For driving dynamos in connection with installations in country houses, a good oil engine is especially useful.

One special feature of this engine is that it uses the common petroleum oil of commerce and not petroleum spirit, which has a very low flashing point. The general arrangement of the engine is similar to a gas engine, the cycle being the same as that of the "Otto." The power is obtained by forcing the oil, which is contained in a small tank, by means of a pressure into a vaporiser, where it becomes mixed with the requisite quantity of air to form a combustible charge, which, being heated, passes into the cylinder. Here it is at first compressed and then fired by an electric spark. The exhaust passes away round the vaporiser and forms the heating power for the incoming charge, and thence passes into the open air through an exhaust pipe. The engine requires little or no attention after

starting, and can be safely left to run on by itself. The cost of working is small and no driver is required. By recent improvements in the engine, the oil consumed has been as low as 1.2 pints per actual horse-power per hour, which at the present cost of oil is less than 1d. per actual horse-power per hour. No lubricating material is required for the cylinder, as the charge itself does all that is necessary in this way. The most general form of the engine is the ordinary horizontal type, two forms of which are supplied—one being the engine itself mounted upon a substantial pole plate and having a separate tank for circulating water, the other form consisting of the engine mounted upon a substantial cast-iron tank or water vessel, which in itself forms a massive foundation. In addition to the horizontal types, a portable engine has lately been introduced, and at the present time the construction of both launch and tramcar engines is under consideration. Many minor improvements have lately been made in the construction and working of these engines, more particularly so as to ensure economical and reliable working, and to still further simplify the attention necessary. A new form of electrical battery has been added, which is an ordinary storage cell which will last for from two to three months working daily, and is easily recharged.

As an additional proof of the value of this engine we have only to add that it secured the silver medal of the Royal Agricultural Society at Nottingham last year.

NEW STAPLES IN UPPER BURMA.

Experiments on an extensive scale of new staples are being made in Upper Burma and the Shan States. The result of the experimental cultivation of wheat in the Shan States has not proved very successful, still the authorities have distributed to some of the Chiefs about 5,400 lb. of seed who have promised to make another trial. Wheat, which was experimented on in the Toungoo and Shwebo districts and tobacco in several other districts, have both proved almost a failure, while the latter plant in Saigong was devoured entirely by insects. It is satisfactory to learn that tobacco cultivation was more encouraging in Lower Burma, especially in the Pegu and Amhurst districts, the leaves obtained there being almost equal to the best samples. As regards vegetables, the prospect is more encouraging, particularly in the Upper Ohindwin and the Jungdwin Valley where beet, onions, lettuces, knol-kohls, sag, and tomatoes flourish luxuriantly.—*M. Mail.*

AGRICULTURE AND THE RICE DUTY IN BURMAH.

Today we publish in another column the concluding part of the Chief Commissioner's Resolution on the Revenue Administration of Burmah for the year 1888-89, in which our readers will find many points of interest. We think every one will agree with the argument therein adduced on the subject of the export duty on rice. Theoretically the tax is objectionable, and when it becomes possible to remit taxation, this tax should be one of the first to go, as it would handicap Burma were other rice-producing countries to compete more seriously than they do in supplying rice to the markets of the world. But at present the tax does very little harm. It is practically equivalent to rather less than a rupee per acre in the land revenue charged on lands cultivated with rice; and the increasing cultivation and growing exports show that, so far, it is no impediment to the progress of Burma as one of the chief suppliers of rice to the world at large. In some special markets, perhaps, it helps to exclude Burma rice; but so long as we can get, as we do, customers for all we can supply at present, and can get remunerative prices for it we can afford to let a few minor markets go. In their case even it is probably not the export duty alone which excludes Burma rice, but the export duty plus the greater distance from these particular markets. Theories are very good things in

their way, but they must not be acted on too rigidly. As a rule, no doubt, any export duty on produce is objectionable, but there are exceptions to every rule, and in this particular case the theoretically objectionable tax could only be got rid of by imposing others which would be much more injurious in practice, however perfectly they might square with theoretical principles. So long as Burma can find a market for all her surplus rice, and that at prices which encourage the spread of cultivation, it is evident that the tax is doing no serious harm. The country is still able to hold her own, and even more, for the exports steadily increase. The export duty could only be removed at the cost of imposing the tax in some other way or by cutting down the expenditure. The latter would be a suicidal policy, as it would tend to promote inefficiency in the administration, and that just when greater efficiency is required rather than less. The imposition of the tax in some other way, as, for instance, in an increased land revenue, would simply be to raise the money with a maximum of friction and at a maximum of cost, while the present mode of raising it causes practically no friction at all, and involves little or no cost. It is easily collected as duty at the ports, the cultivators scarcely realising that they are paying it at all; whereas, if they had to pay it direct to the theogvees all over the country, they would realise it fully and bitterly resent it. Every one who knows the country must agree with Mr. MacDonnell in thinking that to abolish the rice duty, and to increase the land revenue to a corresponding amount, that is, by about 45 lakhs of rupees annually, would be objectionable to the people.

What is wanted in Burma is to induce the people to supplement the income they derive from rice-growing, by cultivating other articles as well, far more than they do. An experimental farm has been started at Lashio in the Northern Shan States, which is under the charge of Mr. Hillier, of the Madras Agricultural College, and this we are glad to learn promises to be a success. It is true that the object of such farms is not so much to establish a paying Government farm, as to spread among the people a knowledge of certain facts and the practice of growing staples which will benefit the country generally. But to get the people to take up the growing of new staples we must not only prove to them that these staples will grow in the country, but also that it will pay the ordinary cultivator to grow them. The want of success of so many such farms is probably due to some extent to the experiments made on them being on too small a scale to convince the people that they will really pay; and partly perhaps, to the system of cultivation being too expensive for the ordinary peasant to adopt on his own account, as well as too scientific to be understood by him. From all we can gather of the working of such farms they are too often experiments which are quite over the heads of the ordinary peasantry. To make them really fruitful in the direction of introducing the production of fresh staples by the people, once it has been proved experimentally on the farm that such staples can be grown, they should be on a larger scale to prove to the people that it pays. So long as a fresh staple is only grown experimentally in a small field of the Government farm, the people are apt to pass it by as merely one more instance of the incomprehensible vagaries of Europeans; but if a large quantity were grown and exported, they would begin to think that there might be money in it. Moreover, so long as an article is produced only in small quantities the upcountry peasant often has a difficulty in disposing of it. No one near him knows exactly what it is worth, or where to find a market for it. All this has to be seen to, and if new industries are to take root they must be carefully nursed through the first few years after their introduction. We trust that the farm at Lashio will prove a permanent success; but although this depends very largely on the zeal and intelligence of the Superintendent, it does not rest entirely with him. The district officers must co-operate with him in explaining the objects of the farm to the people, and, should they be induced to grow new staples, in getting them to market until the ordinary channels of trade are formed.—*Rangoon Gazette.*

OPENING THE FIRST REGULAR TEA PLANTATION IN CHINA.

IMPROVING THE TEA TRADE OF FORMOSA.
